# Ultrasmall cerium oxide nanoparticles as highly sensitive X-ray contrast agents and their antioxidant effect†

Abdullah Khamis Ali Al Saidi,<sup>a</sup> Adibehalsadat Ghazanfari,<sup>a</sup> Ahrum Baek,<sup>b</sup> Tirusew Tegafaw,<sup>a</sup> Mohammad Yaseen Ahmad,<sup>a</sup> Dejun Zhao,<sup>a</sup> Ying Liu,<sup>a</sup> Ji-ung Yang,<sup>c</sup> Ji Ae Park,<sup>c</sup> Byeong Woo Yang,<sup>d</sup> Kwon Seok Chae,<sup>e</sup> Sung-Wook Nam,<sup>f</sup> Yongmin Chang<sup>\*f</sup> and Gang Ho Lee<sup>†a</sup>

Owing to their theranostic properties, cerium oxide (CeO<sub>2</sub>) nanoparticles have attracted considerable attention for their key applications in nanomedicine. In this study, ultrasmall CeO<sub>2</sub> nanoparticles (particle diameter = 1–3 nm) as X-ray contrast agents with an antioxidant effect were investigated for the first time. The nanoparticles were coated with hydrophilic and biocompatible poly(acrylic acid) (PAA) and poly(acrylic acid-co-maleic acid) (PAAMA) to ensure satisfactory colloidal stability in aqueous media and low cellular toxicity. The synthesized nanoparticles were characterized using high-resolution transmission electron microscopy, X-ray diffraction, Fourier transform-infrared spectroscopy, thermogravimetric analysis, dynamic light scattering, cell viability assay, photoluminescence spectroscopy, and X-ray computed tomography (CT). Their potential as X-ray contrast agents was demonstrated by measuring phantom images and *in vivo* CT images in mice injected intravenously and intraperitoneally. The X-ray attenuation of these nanoparticles was greater than that of the commercial X-ray contrast agent Ultravist and those of larger CeO<sub>2</sub> nanoparticles reported previously. In addition, they exhibited an antioxidant effect for the removal of hydrogen peroxide. The results confirmed that the PAA- and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles demonstrate potential as highly sensitive radioprotective or theranostic X-ray contrast agents.

## Introduction

Owing to their excellent physicochemical properties, metal-based nanoparticles have attracted considerable interest in various applications; thus, these nanoparticles provide enticing opportunities to overcome the limitations of existing technologies or to make breakthroughs in a new field.<sup>1–4</sup> Metal-based nanoparticle contrast agents in X-ray computed tomography

(CT) are more sensitive than commercial molecular iodine contrast agents.<sup>5–11</sup> Therefore, they can provide enhanced diagnosis at reduced doses.

As one of the reliable and prevalent imaging modalities owing to its innate ability to provide high-resolution as well as whole-body scan,<sup>12,13</sup> CT is based on high-energy ionizing X-ray radiation *via* which free radicals and reactive oxygen species (ROS) can be generated during an X-ray scan.<sup>14–17</sup> The natural radiation dose is 2–3 mSv per year.<sup>18</sup> Each medical CT scan covers 0.001–16 mSv, depending on the scanning objects of the body; hence, multiple CT scans are harmful to the body.<sup>19</sup> Contrast agents can reduce the X-ray radiation dose without deteriorating the image quality *via* contrast enhancement.<sup>12,13</sup> They also facilitate the identification and diagnosis of certain conditions and diseases of the body.<sup>12,13</sup> Currently, the iodine contrast agents approved by the United States Food & Drug Administration<sup>6,20</sup> exhibit limitations, such as low sensitivity, necessitating high injection doses that could cause side effects,<sup>21</sup> and low contrast for soft tissues. In addition, they undergo rapid renal excretion because of their low molecular masses, allowing only brief imaging times. However, heavy metal-based nanoparticles can overcome these limitations because of their higher X-ray attenuation,<sup>22</sup> lower osmolality

and viscosity,<sup>6,23</sup> and longer blood vessel circulation times<sup>24</sup> than those of molecular iodine contrast agents, leading to higher contrast images, lower injection doses, and longer imaging times. Therefore, developing alternative contrast agents derived from heavy metal-based nanoparticles is imperative.

In particular, cerium oxide (CeO<sub>2</sub>) nanoparticles exhibit an additional unique property of reducing the ionizing risks of X-rays *via* their antioxidant effect based on feasible oxidation state interconversion between Ce<sup>3+</sup> and Ce<sup>4+</sup>.<sup>14–16,25,26</sup> CeO<sub>2</sub> nanoparticles can scavenge free radicals and ROS produced during CT scans, thereby protecting against tissue damage.<sup>26–28</sup> This property of CeO<sub>2</sub> nanoparticles further renders antibacterial and antineurodegenerative therapeutic properties.<sup>29–31</sup>

Thus far, a limited number of Ce-containing nanoparticles have been reported as radioprotective<sup>15</sup> or theranostic<sup>32–36</sup> X-ray contrast agents. Based on the high X-ray attenuation of CeO<sub>2</sub> nanoparticles<sup>22</sup> and their exceptional catalytic properties, rendering them highly effective in removing excess ROS from radiation-induced damage,<sup>26–28</sup> Garcia *et al.* synthesized 5 nm albumin-stabilized CeO<sub>2</sub> nanoparticles and used them for the *in vivo* imaging of normal and tumor-model mice.<sup>15</sup> Chaurand *et al.* successfully located CeO<sub>2</sub> nanomaterials [particle diameter (*d*) = ~31 nm] in mouse lung tissue using X-ray imaging.<sup>32</sup> They reported that the X-ray attenuation was ~2 times greater than that of the commercial iodine contrast agent Iohexol. Liu *et al.* synthesized CeO<sub>x</sub> nanoparticles embedded in mesoporous silica particles (overall diameter = 119–134 nm) and applied them for the diagnosis and X-ray induced photodynamic therapy of cancer.<sup>33</sup> They reported that the X-ray attenuation was 3.79 times greater than that of the iodine contrast agent Iohexol. Cao *et al.* synthesized dextran-coated CeO<sub>2</sub> nanoparticles (*d* = 3 nm) and applied them to CT-guided therapy of inflammatory bowel disease by scavenging ROS and down-regulating proinflammatory cytokines.<sup>34</sup> Naha *et al.* synthesized dextran-coated CeO<sub>2</sub> nanoparticles (*d* = 4.8 nm) and applied them to CT diagnosis of gastrointestinal tract and inflammatory bowel disease.<sup>35</sup> The X-ray attenuation was ~1.2 times greater than that of the commercial iodine contrast agent Iopamidol. Jia *et al.* synthesized doxorubicin-loaded upconversion core@mesoporous CeO<sub>x</sub> shell nanoplatforms (*d* = ~48 nm) for tumor diagnosis *via* CT and the synergistic chemophotodynamic therapy of tumor.<sup>36</sup> Feng *et al.* synthesized citric acid-coated CeO<sub>2</sub> nanoparticles (*d* = ~3 nm) as a renoprotective contrast agent and successfully applied them to *in vivo* spectral CT angiography.<sup>37</sup> Youn *et al.* synthesized CeO<sub>2</sub> nanoparticles (*d* = 3.5 nm) and nanorods (9.4 × 130 nm), and compared their therapeutic effects. Compared to the nanoparticles, the nanorods demonstrated better effects on reducing cerebral edema.<sup>38</sup>

Herein, ultrasmall CeO<sub>2</sub> nanoparticles (*d* = 1–3 nm) coated with hydrophilic and biocompatible polymers, namely, poly(acrylic acid) (PAA) and poly(acrylic acid-co-maleic acid) (PAAMA), were synthesized using the one-pot polyol method. Their particle diameters were less than those<sup>32–39</sup> of the previously investigated nanoparticles. Notably, smaller CeO<sub>2</sub> nanoparticles in particle size can exhibit a higher X-ray attenuation efficiency due to their more effective X-ray attenuation and more

powerful antioxidant effect because of their higher amounts of Ce<sup>4+</sup> on nanoparticle surfaces. Therefore, ultrasmall CeO<sub>2</sub> nanoparticles synthesized herein can act as highly sensitive radioprotective or theranostic X-ray contrast agents. The polymer-coated ultrasmall CeO<sub>2</sub> nanoparticles were characterized using various techniques. Cellular cytotoxicity was assessed to confirm their suitability for biomedical applications. The X-ray attenuation properties were characterized by measuring phantom images. The CT images *in vivo* were measured before and after intravenous (IV) and intraperitoneal (IP) injections to confirm the potential of the CeO<sub>2</sub> nanoparticles as X-ray contrast agents. Finally, their antioxidant effect was evaluated by measuring the removal of hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) in the oxidation reaction of rhodamine B (Rh B) under H<sub>2</sub>O<sub>2</sub>/365 nm ultraviolet (UV) irradiation with and without the nanoparticles.

## Results and discussion

### Colloidal stability, particle diameter, hydrodynamic diameter, zeta potential, and crystallinity

The PAA- and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles, exhibiting colloidal stability, were successfully prepared using a simple one-pot polyol method (Fig. S1†), as confirmed by the below-described characterization methods.

Transparent nanoparticles were suspended in aqueous media, which did not undergo precipitation after synthesis (>1.5 years), indicating excellent colloidal stability (Fig. 1a). The high negative average zeta potentials ( $\zeta_{\text{avg}}$ ) of −48.3 and −43.0 mV for the PAA- and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles in aqueous media, respectively (Fig. 1b and Table 1), confirmed their excellent colloidal stability in aqueous media. The colloidal dispersion was also confirmed by Tyndall

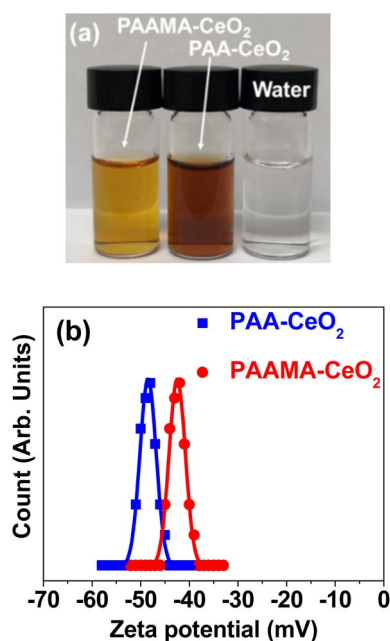

Fig. 1 (a) Photographs of PAA- and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles dispersed in aqueous media and water. (b) Zeta potential ( $\zeta$ ) curves and Gaussian function fits to obtain  $\zeta_{\text{avg}}$ .

effect (Fig. S2†); light scattering was observed only for nanoparticle suspension samples owing to the collision between the nanoparticle colloids and laser light, whereas light scattering was not observed in triple-distilled water.

High-resolution transmission electron microscopy (HRTEM) images of polymer-coated CeO<sub>2</sub> nanoparticles revealed nearly monodisperse particle diameter distributions (Fig. 2a(i), a(ii), b(i) and b(ii)) in which (i) and (ii) label PAA- and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles, respectively. Additional HRTEM

images are provided in ESI (Fig. S3 and S4†). The nanoparticle dispersions were confirmed by elemental mapping in the high-angle annular dark field-scanning transmission electron microscope (HAADF-STEM) mode (Fig. 2c(i) and (ii)), which revealed the uniform elemental distribution of Ce (Fig. 2d(i) and (ii)) in HAADF-STEM images. X-ray energy dispersive spectroscopy spectra (Fig. S5a and b†) confirmed the presence of Ce in the nanoparticles. The average particle diameters ( $d_{\text{avg}}$ ) for PAA- and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles were

**Fig. 2** (a(i)), (a(ii)), (b(i)), and (b(ii)) HRTEM images: nanoparticles enclosed within the dotted circles in (b(i)) and (b(ii)) were magnified as indicated by the arrows (scale bar = 2 nm). (c(i)) and (c(ii)) HAADF-STEM images. (d(i)) and (d(ii)) Elemental mapping in the HAADF-STEM mode. (e) Particle diameter distributions and log-normal function fits to obtain  $d_{\text{avg}}$ . (f) DLS patterns and log-normal function fits to obtain  $a_{\text{avg}}$ . In (a)–(d), (i) indicates PAA-coated ultrasmall CeO<sub>2</sub> nanoparticles and (ii) indicates PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles.

estimated to be 1.8 and 2.0 nm, respectively, based on the log-normal function fits to the observed particle diameter distributions (Fig. 2e and Table 1). The average hydrodynamic diameter ( $a_{\text{avg}}$ ) values of the PAA- and PAAMA-coated ultrasmall  $\text{CeO}_2$  nanoparticles were estimated to be 14.5 and 15.5 nm, respectively, based on the log-normal function fits to the observed dynamic light scattering (DLS) patterns (Fig. 2f). The large hydrodynamic diameter of the nanoparticles was attributed to the PAA and PAAMA coatings on the nanoparticle surfaces and accompanying hydration of a large amount of water. Each monomer in PAA comprises one carboxyl group. PAAMA comprises almost equal numbers of acrylic acid (AA) and maleic acid (MA) monomers, and each of the AA and MA monomers comprises one and two carboxyl groups, respectively. These numerous carboxyl groups possibly lead to strong binding between the polymers and nanoparticles *via* electrostatic (*i.e.*, hard acid-base) interaction, consequently supporting their observed excellent colloidal stability in aqueous media.

The successful synthesis of the nanoparticles was further confirmed by X-ray diffraction (XRD). Before thermogravimetric analysis (TGA), the nanoparticles exhibited very broad peaks, corresponding to a face-centered cubic (FCC) structure and reflecting ultrasmall particle diameters (Fig. 3a). However, after TGA up to 900 °C under airflow, they exhibited sharp peaks (Fig. 3b). All peaks could be assigned to the (hkl) Miller indices (111), (200), (220), (311), (222), (400), (331), (420), (422), and (511) of FCC  $\text{CeO}_2$ , as indicated on the top of the peaks.<sup>40,41</sup> The estimated cell constant (5.406 Å) was consistent with that (5.4113) of bulk  $\text{CeO}_2$  (JCPDS card no. 00-034-0394).<sup>41</sup> Using Scherrer's formula,<sup>42</sup> the diameters of the PAA- and PAAMA-coated ultrasmall  $\text{CeO}_2$  nanoparticles before TGA were estimated to be 1.06 and 1.07 nm, respectively, which were consistent with (or slightly less than) those observed in HRTEM images.

#### Fourier transform-infrared (FT-IR) absorption spectra and TGA curves

The surface coating of PAA and PAAMA on the nanoparticle surfaces was confirmed by FT-IR absorption spectra (Fig. 4a and b, respectively). The surface-coating amount was obtained from the TGA curves (Fig. 4c). As shown in Fig. 4a and b, C-H

symmetric stretching vibration at  $\sim 2930\text{ cm}^{-1}$ ,  $\text{COO}^-$  anti-symmetric stretching vibration at  $\sim 1550\text{ cm}^{-1}$ , and  $\text{COO}^-$  symmetric stretching vibration at  $\sim 1395\text{ cm}^{-1}$  confirmed the successful coating of PAA and PAAMA on the  $\text{CeO}_2$  nanoparticle surfaces. The red-shifts and splittings<sup>43</sup> of the C=O symmetric stretching vibrations of the  $-\text{COOH}$  groups of free PAA and PAAMA at  $\sim 1695\text{ cm}^{-1}$  into the symmetric and antisymmetric  $\text{COO}^-$  stretching vibrations in the FT-IR absorption spectra of the nanoparticle samples confirmed electrostatic (*i.e.*, hard acid-base) bonding<sup>44</sup> between the  $\text{COO}^-$  groups of PAA and PAAMA and  $\text{Ce}^{4+}$  on the nanoparticle surfaces, as observed in other metallic oxide nanoparticles.<sup>45,46</sup> Table S1† also summarizes the observed FT-IR absorption frequencies. The red-shifts of the  $\text{COO}^-$  antisymmetric and symmetric stretching vibrations from the C=O vibrations were  $\sim 140$  and  $\sim 300\text{ cm}^{-1}$  (Table S1†), respectively, confirming the strong bonding. In addition, because PAA and PAAMA comprise many  $-\text{COOH}$  groups, they can bind to a nanoparticle *via* multiple bonds, as schematically drawn in Fig. 4d, consequently leading to the strong bonding of the polymer to the  $\text{CeO}_2$  nanoparticles and the long-term colloidal stability of the polymer-coated nanoparticles in aqueous media (*i.e.*, no precipitation after synthesis, >1.5 years).

The observed good colloidal stability confirmed that a sufficient amount of polymers should be coated on the  $\text{CeO}_2$  nanoparticle surfaces, which was confirmed from the TGA curves in Fig. 4c. The surface-coating amount ( $S$ ) was estimated in wt% by measuring the mass losses after heating from  $\sim 100\text{ °C}$  up to  $900\text{ °C}$  because the initial mass drops (*i.e.*, 6% and 11%) up to  $\sim 100\text{ °C}$  were attributed to the desorption of water and air. Grafting density ( $\sigma$ ),<sup>47,48</sup> defined as the average number of polymers coating a unit surface area of a nanoparticle, was obtained using the bulk density of  $\text{CeO}_2$  ( $7.132\text{ g cm}^{-3}$ ),<sup>49</sup>  $d_{\text{avg}}$  values estimated from HRTEM images, and aforementioned  $S$  values. The average number ( $N_{\text{polymer}}$ ) of polymers coating a nanoparticle was determined as the product of  $\sigma$  and nanoparticle surface area ( $=\pi d_{\text{avg}}^2$ ). Table 1 summarizes the surface-coating results.

#### *In vitro* cytotoxicity results

The PAA- and PAAMA-coated ultrasmall  $\text{CeO}_2$  nanoparticles exhibited very low *in vitro* cellular cytotoxicity (Fig. 5a and b),

Fig. 3 XRD patterns of the powder samples of the PAA- and PAAMA-coated ultrasmall  $\text{CeO}_2$  nanoparticles (a) before and (b) after TGA up to  $900\text{ °C}$  under airflow. The peaks at the top of the peaks are (hkl) Miller indices of bulk  $\text{CeO}_2$  with an FCC crystal structure.

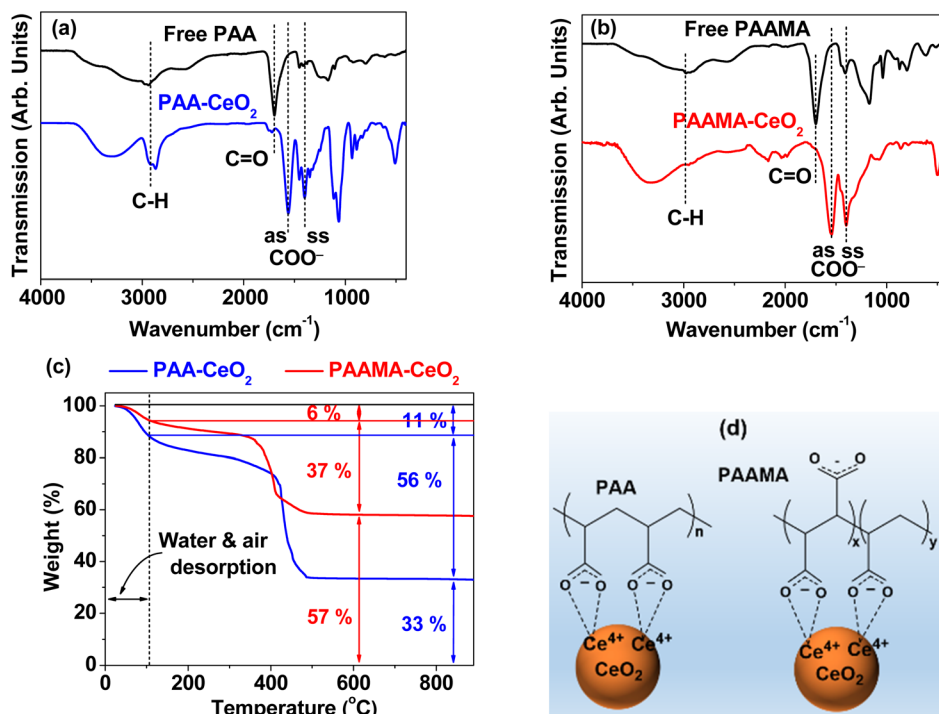

Fig. 4 FT-IR absorption spectra of (a) free PAA and PAA-coated ultrasmall CeO<sub>2</sub> nanoparticles and (b) free PAAMA and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles. "as" and "ss" indicate the antisymmetric and symmetric stretching vibrations of COO<sup>-</sup>, respectively. (c) TGA curves of the PAA- and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles under air flow. (d) Schematic of the coating structures of PAA and PAAMA polymers on the nanoparticle surfaces via electrostatic (*i.e.*, hard acid–base) bonding between the COO<sup>-</sup> groups of the polymers and Ce<sup>4+</sup> on the nanoparticle surfaces (the minor Ce<sup>3+</sup> ions also exist on the nanoparticle surfaces, but only the major Ce<sup>4+</sup> ions were displayed on the nanoparticle surfaces).

thereby demonstrating their suitability for biomedical applications. The high cell viability (>90%) of human prostate cancer (DU145) and normal mouse hepatocyte (NCTC1469) cells up to 500 μM [Ce] 48 h after incubation with nanoparticle samples was observed. Cell morphologies were examined using an optical microscope (Fig. 5c and d). The cell morphologies of the treated cells were similar to those of the control cells, which was consistent with the observed very low cellular cytotoxicity of the nanoparticles.

### Antioxidant effect

To evaluate the antioxidant effect of the PAA- and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles, the degradation of Rh B by oxidation with H<sub>2</sub>O<sub>2</sub> was examined under 365 nm UV irradiation in the presence and absence of the polymer-coated nanoparticles. Decolorization photographs and photoluminescence (PL) spectra of nine solutions prepared in aqueous media were measured as a function of time under UV irradiation: (a) 0.01 mM Rh B, (b) 0.1% H<sub>2</sub>O<sub>2</sub>, (c) PAA- and (d) PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles (0.1 mM [Ce]), (e) 0.01 mM Rh B + 0.05% H<sub>2</sub>O<sub>2</sub>, (f) 0.01 mM Rh B + PAA-coated ultrasmall CeO<sub>2</sub> nanoparticles (0.05 mM [Ce]), (g) 0.01 mM Rh B + PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles (0.05 mM [Ce]), (h) 0.01 mM Rh B + 0.05% H<sub>2</sub>O<sub>2</sub> + PAA-coated ultrasmall CeO<sub>2</sub> nanoparticles (0.05 mM [Ce]), (i) 0.01 mM Rh B + 0.05% H<sub>2</sub>O<sub>2</sub> + PAAMA-coated ultrasmall CeO<sub>2</sub>

nanoparticles (0.05 mM [Ce]). The solution photographs (Fig. 6) and PL spectra (Fig. 7) were measured at intervals of 6 h up to 24 h. Rh B, including other organic dyes, very slowly decomposes under UV irradiation and its decomposition rate depends on the UV irradiation intensity.<sup>50–54</sup> However, Rh B undergoes rapid decomposition in the presence of the oxidizing agent H<sub>2</sub>O<sub>2</sub> under UV irradiation according to the following oxidation reaction,<sup>55</sup>

A similar oxidation reaction of Rh B was observed in the Rh B/H<sub>2</sub>O<sub>2</sub>/hydroxylamine (HA) system in which HA reacted with H<sub>2</sub>O<sub>2</sub> to generate hydroxyl radical ( $\cdot\text{OH}$ ) to decompose Rh B.<sup>55</sup> As shown in Fig. 6, solution-a exhibited an unnoticeable degradation of pink color up to 24 h, indicating that Rh B negligibly decomposed without H<sub>2</sub>O<sub>2</sub> regardless of 365 nm UV irradiation (power = 15 W). Solutions-f and -g also exhibited unnoticeable pink color degradation up to 24 h, indicating that Rh B did not undergo decomposition by the PAA- and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles regardless of the UV irradiation. Solutions-b, -c, and -d were transparent (*i.e.*, no color) because of the absence of Rh B in solutions, indicating that the pink color was solely attributed to Rh B, and not H<sub>2</sub>O<sub>2</sub> and PAA- and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles. In

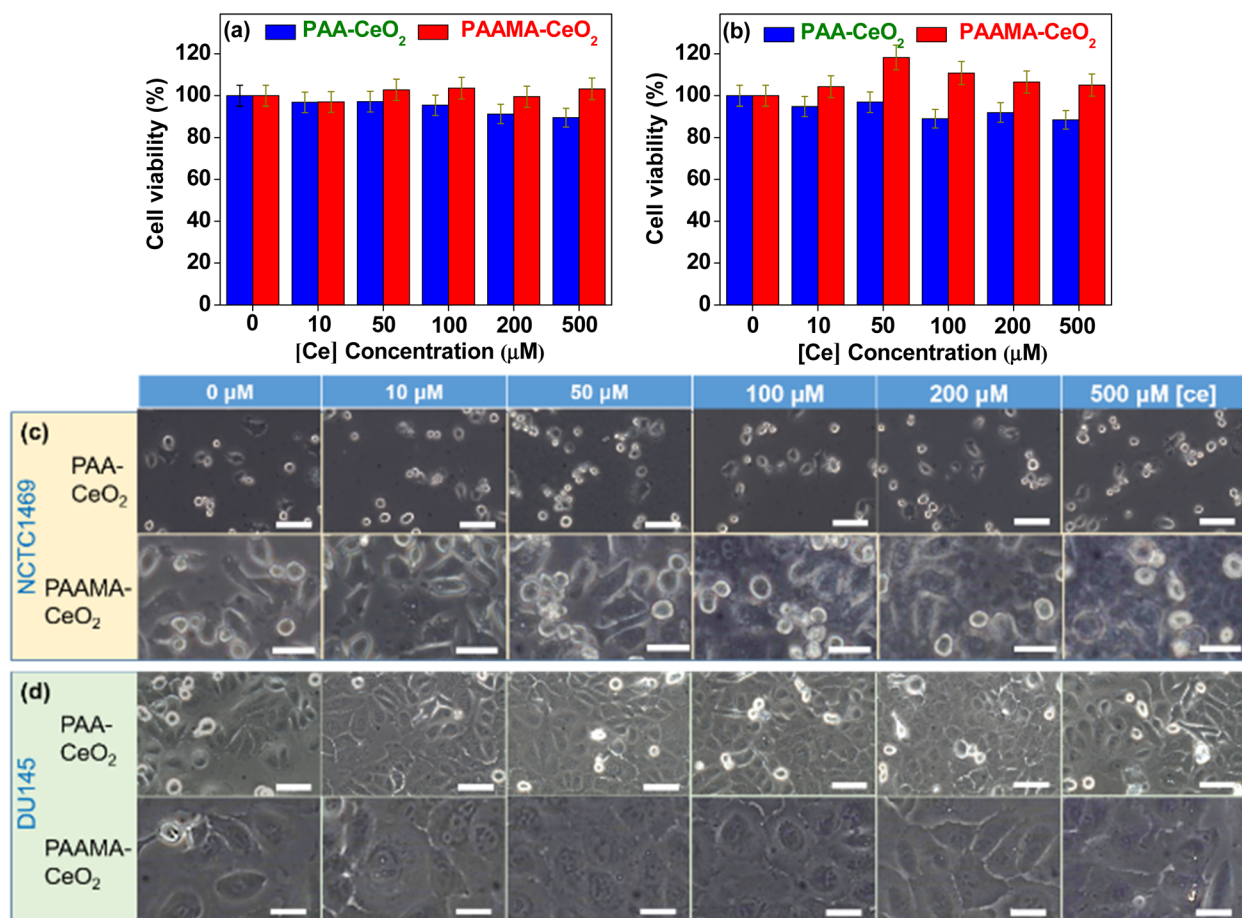

Fig. 5 *In vitro* cell viability of (a) NCTC1469 and (b) DU145 cells and optical microscopy images of (c) NCTC1469 and (d) DU145 cells 48 h after incubation with the PAA- and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles up to 500 μM [Ce]. Scale bar = 70 nm.

the case of solution-e, Rh B rapidly degraded (*i.e.*, rapid pink color degradation) due to the aforementioned oxidation reaction of Rh B with H<sub>2</sub>O<sub>2</sub> under the UV irradiation. By contrast, in solutions-h and -I, the retarded degradation of Rh B (*i.e.*, retarded pink color degradation) was observed due to the antioxidant effect of the PAA- and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles because CeO<sub>2</sub> removed H<sub>2</sub>O<sub>2</sub> according to the following reaction (therefore, the oxidation reaction of Rh B with H<sub>2</sub>O<sub>2</sub> under UV irradiation was retarded by CeO<sub>2</sub>),<sup>56,57</sup>

Therefore, the net antioxidant reaction was as follows:

The antioxidant effects of the PAA- and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles were quantitatively investigated by recording PL spectra (Fig. 7a–f). Solutions-a, -f, and -g exhibited an unnoticeable PL intensity drop with time up to

24 h (Fig. 7a, c and d, respectively), which was consistent with the observation of unnoticeable pink color degradation in the solution photographs in Fig. 6a, f and g, respectively. The PL spectra of solutions-b, -c, and -d were not measured because Rh B was absent in the solutions. Solution-e exhibited a rapid drop in the PL intensity with time (Fig. 7b), whereas solutions-h and -i containing nanoparticles exhibited a delayed drop in the PL intensity (Fig. 7e and f, respectively), confirming the antioxidant effect of the nanoparticles. To quantitatively evaluate the degradation efficiency (%) of Rh B with time, defined as  $100(I_0 - I_t)/I_0$ , where  $I_t$  is the PL intensity at time  $t$ , it was plotted as a function of time in Fig. 7g. Solutions-a, -f, and -g exhibited a negligible degradation efficiency of Rh B overtime. Solution-e rapidly exhibited ~100% degradation efficiency of Rh B at 12 h, whereas solutions-h and -i exhibited only ~78% degradation efficiency of Rh B at 24 h due to the antioxidant effect of the nanoparticles. This result confirmed the antioxidant effect of the PAA- and PAAMA-coated CeO<sub>2</sub> nanoparticles; therefore, these nanoparticles exhibited potential as radioprotective or theranostic X-ray contrast agents by removing ROS (*i.e.*, H<sub>2</sub>O<sub>2</sub> and ·OH) produced by X-rays during X-ray scan.

Fig. 6 Photographs of various solutions up to 24 h: (a) 0.01 mM Rh B, (b) 0.1%  $\text{H}_2\text{O}_2$ , (c) PAA- and (d) PAAMA-coated ultrasmall  $\text{CeO}_2$  nanoparticles dispersed in aqueous media (0.1 mM [Ce]), (e) 0.01 mM Rh B + 0.05%  $\text{H}_2\text{O}_2$ , (f) 0.01 mM Rh B + PAA-coated ultrasmall  $\text{CeO}_2$  nanoparticles (0.05 mM [Ce]), (g) 0.01 mM Rh B + PAAMA-coated ultrasmall  $\text{CeO}_2$  nanoparticles (0.05 mM [Ce]), (h) 0.01 mM Rh B + 0.05%  $\text{H}_2\text{O}_2$  + PAA-coated ultrasmall  $\text{CeO}_2$  nanoparticles (0.05 mM [Ce]), (i) 0.01 mM Rh B + 0.05%  $\text{H}_2\text{O}_2$  + PAAMA-coated ultrasmall  $\text{CeO}_2$  nanoparticles (0.05 mM [Ce]). U = 365 nm UV irradiation (power = 15 W) and N = no UV irradiation.

### X-ray attenuation: phantom images

The contrasts of the PAA- and PAAMA-coated ultrasmall  $\text{CeO}_2$  nanoparticles in the X-ray phantom images were brighter than those of a commercial molecular iodine(I) contrast agent Ultravist at similar atomic concentrations of [Ce] and [I] (Fig. 8a), demonstrating that the PAA- and PAAMA-coated ultrasmall  $\text{CeO}_2$  nanoparticles were superior than Ultravist. This result was attributed to the higher linear X-ray attenuation coefficient of Ce than that of I (Fig. 8b).<sup>22</sup> To quantitatively discuss this result, X-ray attenuation estimated from X-ray phantom images was plotted as a function of the atomic concentration. The X-ray attenuation of the PAA- and PAAMA-coated ultrasmall  $\text{CeO}_2$  nanoparticles was greater than that of Ultravist at the same atomic concentration of [Ce] and [I] at 70 kV<sub>p</sub> (Fig. 8c). In addition, Fig. 8d shows the X-ray attenuation of the nanoparticles as a function of the number density: the X-ray attenuation at the same number density was greater than that observed at the same atomic concentration: therefore, nanoparticle contrast agents can provide considerably higher contrast enhancement than molecular agents at the same number density, making the nanoparticle contrast agents superior than molecular contrast agents. The number density was estimated by multiplying the molar atomic concentration with  $6.02 \times 10^{23}/N_{\text{atom}}$ , where  $N_{\text{atom}}$  is the number of X-ray attenuating atoms per molecule or nanoparticle;  $N_{\text{atom}}$  is three for Ultravist, and  $\sim(1/3) (d_{\text{avg}}/h)^3 = 150$  and 205 for PAA- and PAAMA-coated ultrasmall  $\text{CeO}_2$  nanoparticles,<sup>58</sup>

respectively; in the above formula,  $h$  represents the average ionic diameter of the atoms per chemical formula  $[=2\{0.101 (\text{Ce}^{4+}) + 2 \times 0.126 (\text{O}^{2-})\}/3 = 0.235 \text{ nm}]$ .<sup>59</sup>

As a key parameter for comparing materials as X-ray contrast agents, the X-ray attenuation efficiency ( $\eta$ ), defined as the X-ray attenuation per molar concentration [Hounsfield units (HU)/mM] or per number density [HU/(1/L)], was estimated from the slopes in Fig. 8c and d, respectively. Table 2 summarizes the results. The  $\eta$  values of the nanoparticles were 1.3 and 68 times greater than those of Ultravist in terms of the molar atomic concentration and number density, respectively. In addition, the  $\eta$  value estimated herein was greater than those<sup>35,39</sup> of larger  $\text{CeO}_2$  nanoparticles (Fig. 8e). This result was attributed to the particle size effect, *i.e.*, smaller nanoparticles can attenuate X-rays more effectively than larger nanoparticles because of the exponential decay of X-rays along the penetration depth. Therefore, the results obtained herein revealed that the PAA- and PAAMA-coated ultrasmall  $\text{CeO}_2$  nanoparticles demonstrate promise as highly sensitive X-ray contrast agents.

### In vivo CT images

The potential of the nanoparticles as X-ray contrast agents was further confirmed *in vivo* using the PAA-coated ultrasmall  $\text{CeO}_2$  nanoparticles. The nanoparticles dispersed in aqueous media were injected *via* two routes: intravenously (IV) *via* the mice tails and intraperitoneally (IP). The CT images were recorded before and after injection using an injection dose of  $\sim 0.1$  mmol Ce per kg, which was less than that ( $>1$  mmol I per kg)<sup>6,20</sup> of the iodine contrast agents. Positive contrast enhancement was observed in the mice bladder after IV and IP injections even at an injection dose of  $\sim 10$  times less than those of iodine contrast agents (Fig. 9a). The contrasts were quantitatively shown in Fig. 9b by plotting the signal-to-noise ratio (SNR) of a region of interest (ROI) at the bladder as a function of time. Compared with the IP injection, the IV injection exhibited a more rapid SNR increase and drop due to the faster excretion of the nanoparticles after the IV injection than that after the IP injection.<sup>60,61</sup> This *in vivo* result confirmed that the PAA- and PAAMA-coated ultrasmall  $\text{CeO}_2$  nanoparticles demonstrate potential as CT contrast agents.

## Experimental

### Synthesis of polymer-coated ultrasmall $\text{CeO}_2$ nanoparticles (polymer = PAA and PAAMA)

The schematic of the one-pot polyol synthesis<sup>58,62</sup> is shown in Fig. S1,† and details of the synthesis are provided in ESI.† In this method, triethylene glycol (TEG) as solvent suppressed the particle size growth, leading to TEG-coated ultrasmall  $\text{CeO}_2$  nanoparticles. Then, TEG was replaced with PAA (or PAAMA) because  $-\text{COOH}$  groups of the PAA (or PAAMA) can more strongly bind to the  $\text{CeO}_2$  nanoparticles than  $-\text{OH}$  group of the TEG.

### General characterization

The synthesized nanoparticles were characterized as described in detail in previous studies.<sup>58,62</sup> The Ce

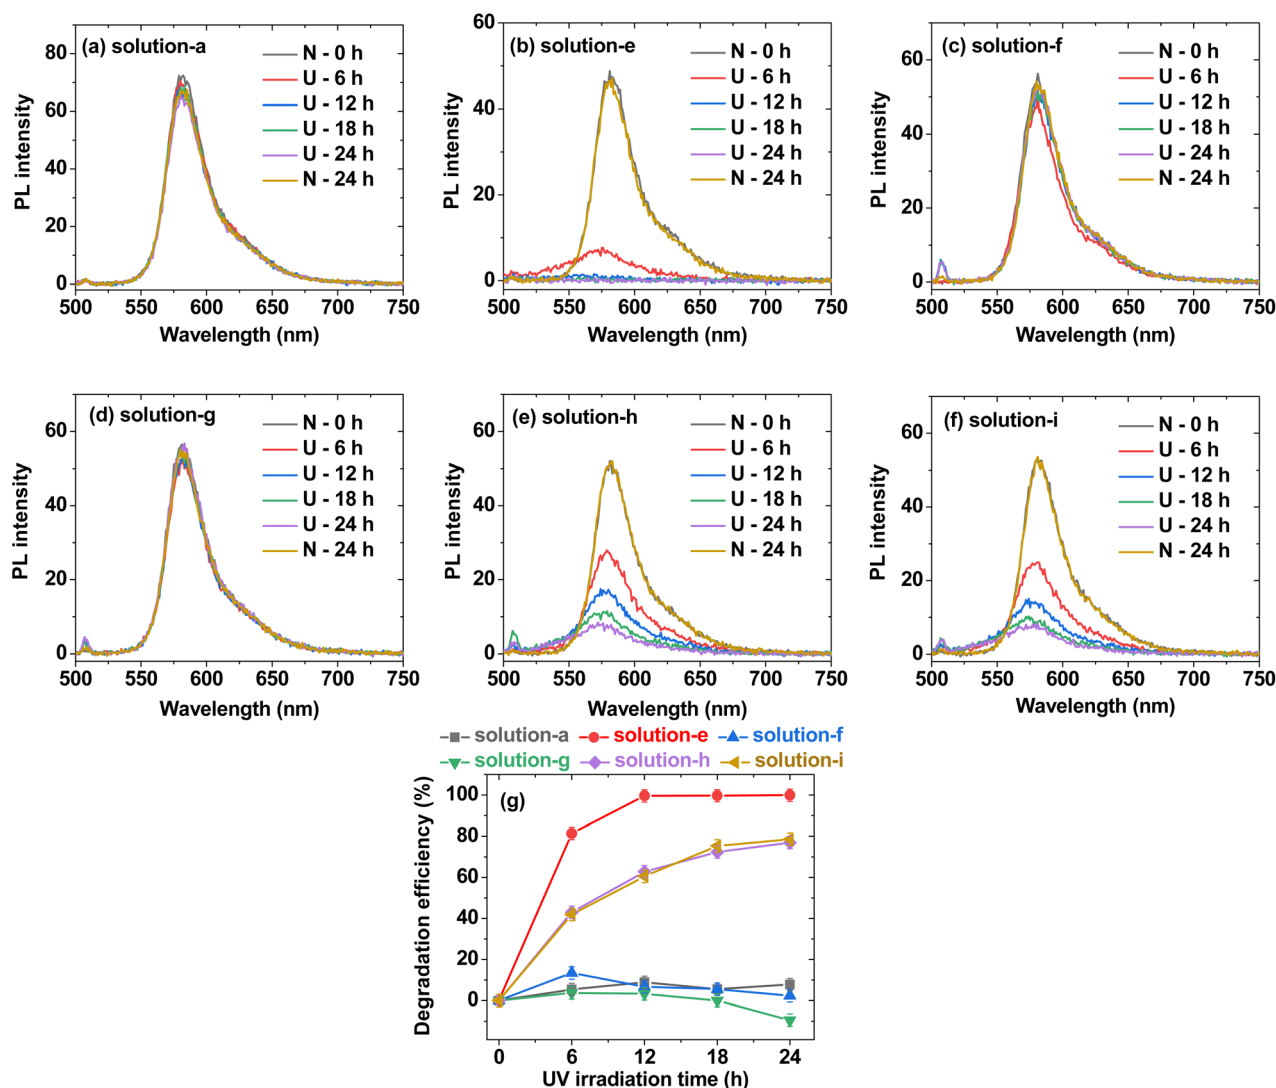

Fig. 7 PL spectra of (a) solution-a (i.e., 0.01 mM Rh B), (b) solution-e (i.e., 0.01 mM Rh B + 0.05%  $\text{H}_2\text{O}_2$ ), (c) solution-f (i.e., 0.01 mM Rh B + PAA-coated ultrasmall  $\text{CeO}_2$  nanoparticles (0.05 mM [Ce])), (d) solution-g (i.e., 0.01 mM Rh B + PAAMA-coated ultrasmall  $\text{CeO}_2$  nanoparticles (0.05 mM [Ce])), (e) solution-h (i.e., 0.01 mM Rh B + 0.05%  $\text{H}_2\text{O}_2$  + PAA-coated ultrasmall  $\text{CeO}_2$  nanoparticles (0.05 mM [Ce])), (f) solution-i (i.e., 0.01 mM Rh B + 0.05%  $\text{H}_2\text{O}_2$  + PAAMA-coated ultrasmall  $\text{CeO}_2$  nanoparticles (0.05 mM [Ce])) in Fig. 6: U = 365 nm UV irradiation and N = no UV irradiation. (g) Plots of Rh B degradation efficiency (%) for solutions-a, -e, -f, -g, -h, and -i in Fig. 6.

concentration of the nanoparticle suspension in aqueous media was measured by inductively coupled plasma-atomic emission spectrometry (Avio500, PerkinElmer, Waltham, MA, USA). The particle diameters of the PAA- and PAAMA-coated ultrasmall  $\text{CeO}_2$  nanoparticles were estimated by HRTEM (Titan G2 ChemiSTEM CS Probe, FEI, Hillsboro, OR, USA) operating at an accelerating voltage of 200 kV. Hydrodynamic diameters (a) and zeta potentials ( $\zeta$ ) were measured using a particle size analyzer (Zetasizer Nano ZS, Malvern Panalytical, Malvern, UK) with diluted samples ( $\sim 0.1$  mM [Ce]). The crystal structure of the powder samples before and after TGA was measured using a multipurpose powder XRD spectrometer (X-PERT PRO MRD, Philips, Eindhoven, The Netherlands) with unfiltered  $\text{CuK}\alpha$  ( $\lambda = 1.54184 \text{ \AA}$ ) radiation. The surface coating of the polymers on nanoparticle surfaces was confirmed by recording FT-IR absorption spectra (Galaxy

7020A, Mattson Instruments, Inc., Madison, WI, USA) using dried powder samples pelletized in KBr. The surface-coating amount of polymers on nanoparticle surfaces was estimated by recording TGA curves (SDT-Q600, TA Instruments, New Castle, DE, USA) between room temperature ( $\sim 20^\circ \text{C}$ ) and  $900^\circ \text{C}$  under airflow. The antioxidant effect was measured by recording PL spectra (Cary Eclipse, Agilent Technologies) of various solutions of Rh B and  $\text{H}_2\text{O}_2$  in aqueous media under 365 nm UV irradiation (15 W, Vilber Lourmat, Cedex 1, France) in the presence and absence of the nanoparticle samples.

#### *In vitro* cell viability measurements

The *in vitro* cytotoxicity of polymer-coated ultrasmall  $\text{CeO}_2$  nanoparticles was measured using the DU145 and NCTC1469

**Fig. 8** (a) X-ray phantom images of Ultravist and PAA- and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles dispersed in aqueous media at an X-ray source voltage of 70 kV<sub>p</sub>. (b) Plot of the linear attenuation coefficients of Ce and I versus radiation photon energy. Plots of the X-ray attenuation as a function of the (c) atomic concentrations of [Ce] and [I] and (d) number density of the nanoparticles and Ultravist: slopes of the dotted lines correspond to X-ray attenuation efficiencies ( $\eta$ ). (e) Comparison of  $\eta$  values: dextran-coated CeO<sub>2</sub> nanoparticles ( $d = 4.8$  nm, 80 kV<sub>p</sub>),<sup>35</sup> porous Ce<sub>2</sub>(CO<sub>3</sub>)<sub>2</sub>O·H<sub>2</sub>O nanoparticles ( $d = 196.6$  nm, 80 kV<sub>p</sub>),<sup>39</sup> and polymer-coated ultrasmall CeO<sub>2</sub> nanoparticles [ $d = (1.8 + 2.0)/2 = 1.9$  nm, 70 kV<sub>p</sub>] (this study). Water: 0 HU.

cell lines. A cell viability assay kit (CellTiter-Glo, Promega, Madison, WI, USA) was used. The adenosine triphosphate content was measured using a luminometer (Victor 3, PerkinElmer, Waltham, MA, USA). The cells were seeded onto a 24-well cell culture plate ( $5 \times 10^4$  cell density, 500  $\mu$ L cells per well) and incubated for 24 h (5% CO<sub>2</sub>, 37 °C). Five test nanoparticle solutions (10, 50, 100, 200, and 500  $\mu$ M [Ce], respectively) in a sterile phosphate buffer saline solution (PBS) were prepared by diluting the original concentrated nanoparticle suspension ( $\sim 50$  mM [Ce]) with PBS. Approximately 2  $\mu$ L of each test solution was added to the cells and the treated cells were incubated

for 48 h. The cell viabilities were measured thrice, and the average values were normalized with respect to those of the control cells (*i.e.*, untreated cells with nanoparticle samples).

#### X-ray phantom image measurements

X-ray attenuation was estimated by measuring X-ray phantom images using a micro-CT scanner (Inveon, Siemens Healthcare, Erlangen, Germany) at an X-ray source voltage of 70 kV<sub>p</sub>, an X-ray source current of 280  $\mu$ A, and an imaging time per frame of 300 ms. It was estimated in HU with respect to that of water with 0.0 HU using the formula  $HU = 1000 (\mu_{\text{sample}} - \mu_{\text{water}})/$

**Table 2** Summary of the observed X-ray attenuation properties of Ultravist and PAA- and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles dispersed in aqueous media at 70 kV<sub>p</sub>

Chemical	$N_{\text{atom}}$	Concentration (mM [Ce] or [I])	Number density (1/L) $\times 10^{20}$	X-ray attenuation (HU)		X-ray attenuation efficiency ( $\eta$ )	
				70 kV <sub>p</sub>	(HU/mM)	[HU/(1/L)] $\times 10^{-19}$	
PAA-CeO <sub>2</sub>	150	52.1	2.1	344	6.6	16.9	
PAAMA-CeO <sub>2</sub>	205	43.7	1.3	282			
Ultravist	3	100	200.7	487	5.0	0.25	
	3	50	100.3	273			
	3	25	50.2	82			
	3	5	10.0	24			

**Fig. 9** (a) *In vivo* CT images of the mice bladder before and after intravenous (IV) and intraperitoneal (IP) injections of an aqueous suspension sample of PAA-coated ultrasmall CeO<sub>2</sub> nanoparticles at 70 kV<sub>p</sub>. The dotted circles at the bladder indicate the region of interest (ROI). (b) Contrast plots of the SNR-ROI of the bladder as a function of time.

$\mu_{\text{water}}$ , where  $\mu$  is the measured linear attenuation coefficient of the material from the phantom images.

### Animal studies

All animal procedures were performed in accordance with the Guidelines for Care and Use of Laboratory Animals of Kyungpook National University (KNU) (IV injection experiment) and Korea Institute of Radiological & Medical Science (KIRAMS) (IP injection experiment) and approved by the Animal Ethics Committee of KNU and KIRAMS (permission no. 2022-0345 and kirams2023-0012, respectively).

### *In vivo* CT image measurements

Female ICR mice (ICR = Institute of Cancer Research, USA) with a weight of ~40 g were injected with 0.1 mmol Ce per kg and used for imaging. For imaging, the mice were anesthetized using 1.5% isoflurane in oxygen, and measurements were conducted before and after IV injection with the PAA-coated ultrasmall CeO<sub>2</sub> nanoparticles dispersed in aqueous media into the mice tails under the following conditions: number of mice ( $N$ ) = 2, X-ray source voltage = 70 kV<sub>p</sub>, X-ray source current = 280  $\mu$ A, imaging time per frame = 1700 ms, thickness = 0.148 mm, and resolution = 512  $\times$  512. The measurements were also conducted before and after IP injection (200  $\mu$ L). After measurements, the mice were revived from anesthesia and placed in a cage with free access to food and water.

## Conclusions

Hydrophilic and biocompatible PAA- and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles ( $d_{\text{avg}}$  values of 1.8 and 2.0 nm, respectively, the smallest size reported thus far) were synthesized using the one-pot polyol method.

(1) The nanoparticles exhibited excellent colloidal stability (*i.e.*, no precipitation after synthesis, >1.5 years) and low cellular toxicity (*i.e.*, >90% cell viability).

(2) Their X-ray attenuation efficiency was 1.3 times greater than that of Ultravist. Furthermore, it was greater than those of various large CeO<sub>2</sub> nanoparticles reported previously.

(3) They exhibited an antioxidant effect for the removal of H<sub>2</sub>O<sub>2</sub>.

(4) The results from *in vivo* mice experiments confirmed that the nanoparticles exhibited contrast enhancement after IV and IP injections. All these results suggested that PAA- and PAAMA-coated ultrasmall CeO<sub>2</sub> nanoparticles are highly sensitive X-ray contrast agents with antioxidant effects.
