Antineoplastic indole-containing compounds with potential VEGFR inhibitory properties†

Dalia R. Aboshouk, ^a M. Adel Youssef, ^b Mohamed S. Bekheit, ^a Ahmed R. Hamed ^c and Adel S. Girgis ^{*a}

Cancer is one of the most significant health challenges worldwide. Various techniques, tools and therapeutics/materials have been developed in the last few decades for the treatment of cancer, together with great interest, funding and efforts from the scientific society. However, all the reported studies and efforts seem insufficient to combat the various types of cancer, especially the advanced ones. The overexpression of tyrosine kinases is associated with cancer proliferation and/or metastasis. VEGF, an important category of tyrosine kinases, and its receptors (VEGFR) are hyper-activated in different cancers. Accordingly, they are known as important factors in the angiogenesis of different tumors and are considered in the development of effective therapeutic approaches for controlling many types of cancer. In this case, targeted therapeutic approaches are preferable to the traditional non-selective approaches to minimize the side effects and drawbacks associated with treatment. Several indole-containing compounds have been identified as effective agents against VEGFR. Herein, we present a summary of the recent indolyl analogs reported within the last decade (2012–2023) with potential antineoplastic and VEGFR inhibitory properties. The most important drugs, natural products, synthesized potent compounds and promising hits/leads are highlighted. Indoles functionalized and conjugated with various heterocycles beside spiroindoles are also considered.

1. Introduction

Cancer is one of the most significant health challenges worldwide. It is the second most fatal disease globally after cardiovascular disorders.¹ About 19–20 million people are diagnosed with different cancer types every year and many of them lose their life.² Although many techniques, tools and therapeutics/materials have been developed in the last few decades, none of them are effective in controlling the various types of cancer at different stages, especially the advanced ones.³ To date, this

M. Adel Youssef

challenge is still a significant task despite the great interest, funding and efforts from the entire scientific society (including research institutes and pharmaceutical companies).⁴ Recently, progress has been achieved in cancer chemotherapy due to the efforts devoted to developing selective molecular therapeutics. Although traditional non-selective therapeutics are still employed clinically, their drawbacks/side effects and poor survival rates are major problems, limiting their applications. Additionally, the early detection of this disease is challenging, although it is the most appropriate opportunity for curing it.^{5,6}

To date, 90 protein tyrosine kinases have been identified among the known 518 kinases.⁷ Tyrosine kinases are capable of many diverse cellular functions including growth, proliferation, differentiation and death.⁸ Tyrosine kinases can catalyze the phosphorylation of tyrosine utilizing the adenosine triphosphate (ATP) molecule, which can be classified into receptor and non-receptor types. The receptor category include transmembrane, extracellular and intracellular, whereas the non-

receptors are intracellular.⁹ The overexpression of tyrosine kinases is associated with cancer proliferation and/or metastasis, indicating their importance as cancer chemotherapeutics.^{10,11}

Angiogenesis is an essential biological process for the formation/extension of new blood capillaries from the vessels present in the vascular system. Thus, it is an essential process for growth, menstruation, embryonic development, wound healing, functional repair and many pathological disorders including cancer. Furthermore, it is one of the main functions for delivering vital supplies including nutrients and oxygen to cells and removal of waste. Angiogenesis is also a critical process for tumor progression and metastasis. Many growth factors (VEGF: vascular endothelial growth factor, EGF: epidermal growth factor, and FGF: fibroblast growth factor) can stimulate angiogenesis.¹²⁻¹⁵ VEGF can be categorized into different classes (VEGF-A, B, C, and D), which can bind to diverse tyrosine kinase receptors (VEGFR-1, 2, and 3). Notably, VEGF and its receptors are hyper-activated in different cancers, and thus considered an important target for combating this disease. VEGFR-2 is the most well-known factor for angiogenesis of various solid tumors (colon, breast, ovary, lung, skin, renal, head, neck, lymphoma, etc.). Several drugs with inhibitory VEGFR-2 activity have been recognized and clinically approved as anticancer drugs.^{12,13,16} Anti-angiogenic active agents reduce the vascular permeability and enhance the extravasation of the therapeutic small molecules.¹⁷ However, some adverse effects have been reported to be associated with anti-VEGFR therapeutics including dermatologic disorders (skin rash, depigmentation and mucositis), painful hand-foot skin reactions and pruritus.¹⁸

Accordingly, multi-targeted inhibitory drugs/candidates have become a recent trend in cancer chemotherapy, attracting significant attention and research interest. Interest in this strategy is attributed to the multifactorial nature of many cancer

and international research projects.

Mohamed S. Bekheit, Associate Professor in the National Research Center, Egypt since 2018. He received his PhD from Ain-Shams University, Egypt (2013). His research studies focus on design and synthesis of heterocyclic compounds of potential biological properties, together with interest in organo-phosphorus chemistry with special interest in computational chemistry techniques. He has participated in several national and international research projects.

Ahmed R. Hamed
and international research projects. His research studies are focused on the design and synthesis of heterocyclic compounds with potential biological properties, with special interest in computational chemistry techniques.

Adel S. Girgis, Emeritus Professor at the National Research Centre (NRC), Egypt. He received his PhD from Cairo University, Egypt in 1997 and was promoted to Full Professor of Organic Chemistry at the National Research Centre, Egypt in 2009. He joined the research group of Prof. Alan R. Katritzky (Center of Heterocyclic Compounds, University of Florida, USA) in 2008 and 2013. He received many national and international research funds. His research studies are focused on the design and synthesis of heterocyclic compounds with potential biological properties, with special interest in computational chemistry techniques.

types.⁷ Additionally, carcinoma cell initiation and proliferation involve various receptors and signaling pathways. Moreover, multi-target inhibitors can overcome cancer cell resistance, which is an advantage for multi-targeted treatment compared to single-targeted treatment or cocktail of multi-component drugs.^{7,19}

The indolyl scaffold occupies a unique position among the diverse alkaloids due to the wide range of bio-properties of its natural and synthesized analogs. Many natural alkaloids are well known, among which melatonin **1** is a natural hormone biosynthesized in the dark by the pineal gland²⁰ (Fig. 1). Recently, clinical trials supported its positive impact on the prevention or treatment COVID-19 infection upon being administered alone or in combination with other therapeutics.^{21–24} Serotonin **2** is a neurotransmitter that controls many human functions such as mood, appetite, sleep and social behavior.²⁵

Many indole-containing drugs have been approved and in clinical use for a long time, among which indomethacin **3** is a famous non-steroidal anti-inflammatory drug (approved by the FDA “Food and Drug Administration” since 1965)²⁶ with inhibitory properties against cyclooxygenase (COX), an enzyme controlling the formation of prostaglandin from arachidonic acid.²⁷ Delavirdine **4** (FDA approval in 1997) is an anti-HIV (human immunodeficiency virus) drug.^{28,29} Umifenovir **5** (approved in Russia and China) is an anti-influenza drug repurposed for the treatment of SARS-CoV-2.^{30–33} Pindolol **6** (antihypertensive drug, non-cardioselective β -blocker, FDA

approval in 1982)³⁴ and Maxalt **7** (antimigraine agent, FDA approval in 1998)³⁵ are also indole analogs. Cipargamin **8** exhibits high efficacy against protein synthesis in *Plasmodium falciparum*. In addition, it has entered pre-clinical trial investigations as a potential antimalarial drug.³⁶

The current study aims to describe and highlight the indole-containing compounds with potential anti-VEGFR properties. Specifically, the relevant keywords were input in different search engines such as Scopus, ScienceDirect and PubMed. The recent advances in this subject (last decade, 2023–2012) with the greatest diversification revealing promising bio-properties will be discussed.

2. Indole-containing drugs and potent agents

2.1. Sunitinib

Sunitinib (Sutent) **9** (Fig. 2) is an oral antitumor multi-targeted tyrosine kinase inhibitor (VEGFR-1, -2, -3; PDGFR- α , - β : platelet-derived growth-factor receptor; and c-kit: stem cell factor receptor) against FLT3, which is an FMS-like tyrosine kinase inhibitor with potent anti-angiogenesis properties.^{16,37–39} It is clinically approved against advanced renal and imatinib-resistant gastrointestinal (FDA approval in 2006) and pancreatic cancers (FDA approval in 2011). It has also been given FDA approval (2017) for adult adjuvant treatment at high risk of

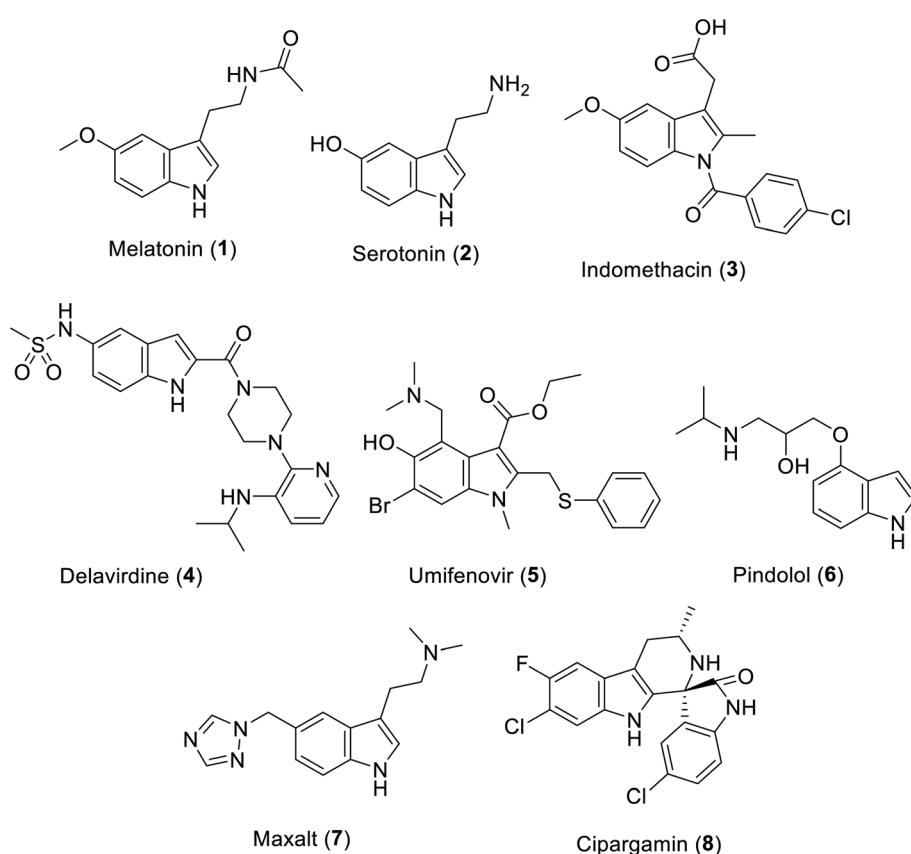

Fig. 1 Clinically approved indole-containing drugs (1–7) and cipargamin (8).

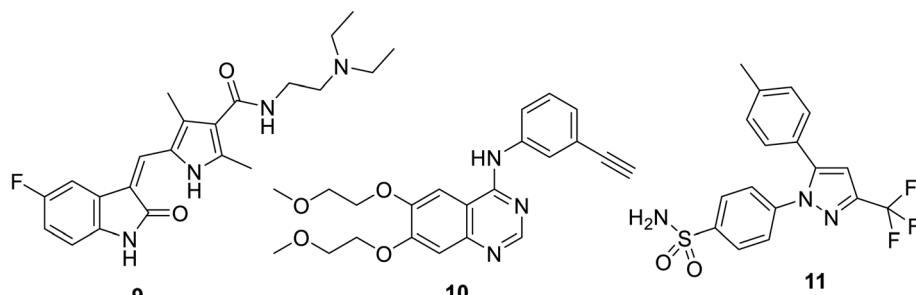

Fig. 2 Sunitinib (sutent) 9 multi-targeted tyrosine kinase inhibitor, erlotinib 10 (EGFR inhibitor) and celecoxib 11 (COX-inhibitor).

renal cancer.^{40,41} However, due to the side effects/drawbacks (diarrhea, fatigue, hypertension, hematologic toxicities, cardiotoxic effects and hand-foot syndrome)^{39,42-44} observed during clinical administration, many studies proposed the combination of sunitinib with another chemotherapeutic agent or radiation. This approach can reduce the unintended side effects and enhance the efficacy of the drug.⁴²

Also, sunitinib can be useful in the treatment of melanoma, which was supported by pre-clinical studies revealing the initiation of tumor hypoxia in melanoma xenografts.¹⁶ An obvious objective response by solid tumors to sunitinib including metastatic breast, colon, neuroendocrine and non-small cell lung cancers (NSCLC) was reported.^{39,42,45}

A synergistic effect was observed upon the combination of sunitinib with erlotinib 10 (EGFR: epidermal growth factor receptor, inhibitor) for the treatment of NSCLC A549 xenograft mice⁴⁶ (Fig. 2). Pre-clinical model studies supported that the combination of PRX177561 (CXC4, chemokine receptor type 4 antagonist) with sunitinib enhanced the therapeutic efficacy (reducing the tumor proliferation and extending the disease-free survival) against glioblastoma (brain cancer).^{47,48} *In vivo* studies supported that a COX-2 (cyclooxygenase-2) inhibitor (celecoxib 11) can enhance the activity of sunitinib in mice bearing human renal cancer xenografts *via* the observation of delay in tumor progression.⁴⁹

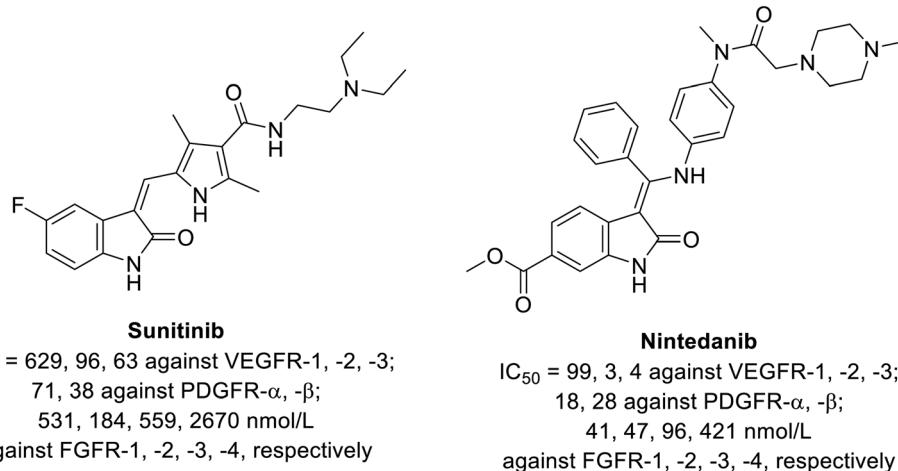

Fig. 4 Inhibitory properties of sunitinib and nintedanib against tyrosine kinases (VEGFR-1, -2, -3; PDGFR- α , - β and FGFR-1, -2, -3, -4).⁵²

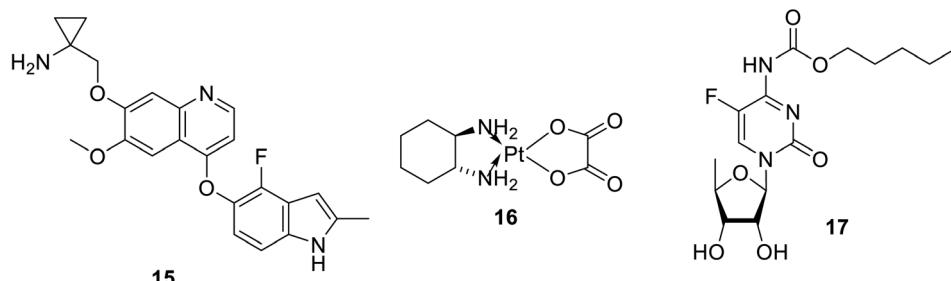

Fig. 5 Anlotinib 15 (a multi-targeted tyrosine kinase inhibitor), oxaliplatin 16 capecitabine 17.

2.2. Nintedanib

Nintedanib (12) (Ofev and Vargatef) is also an oral multi-targeted tyrosine kinase inhibitor (VEGFR-1, -2, -3; PDGFR- α , - β and

FGFR-1, -2, -3, -4: fibroblast growth-factor receptor)⁵⁰⁻⁵⁴ (Fig. 3 and 4). The FDA approved its use for the treatment of idiopathic lung fibrosis (2014), systemic sclerosis-associated interstitial

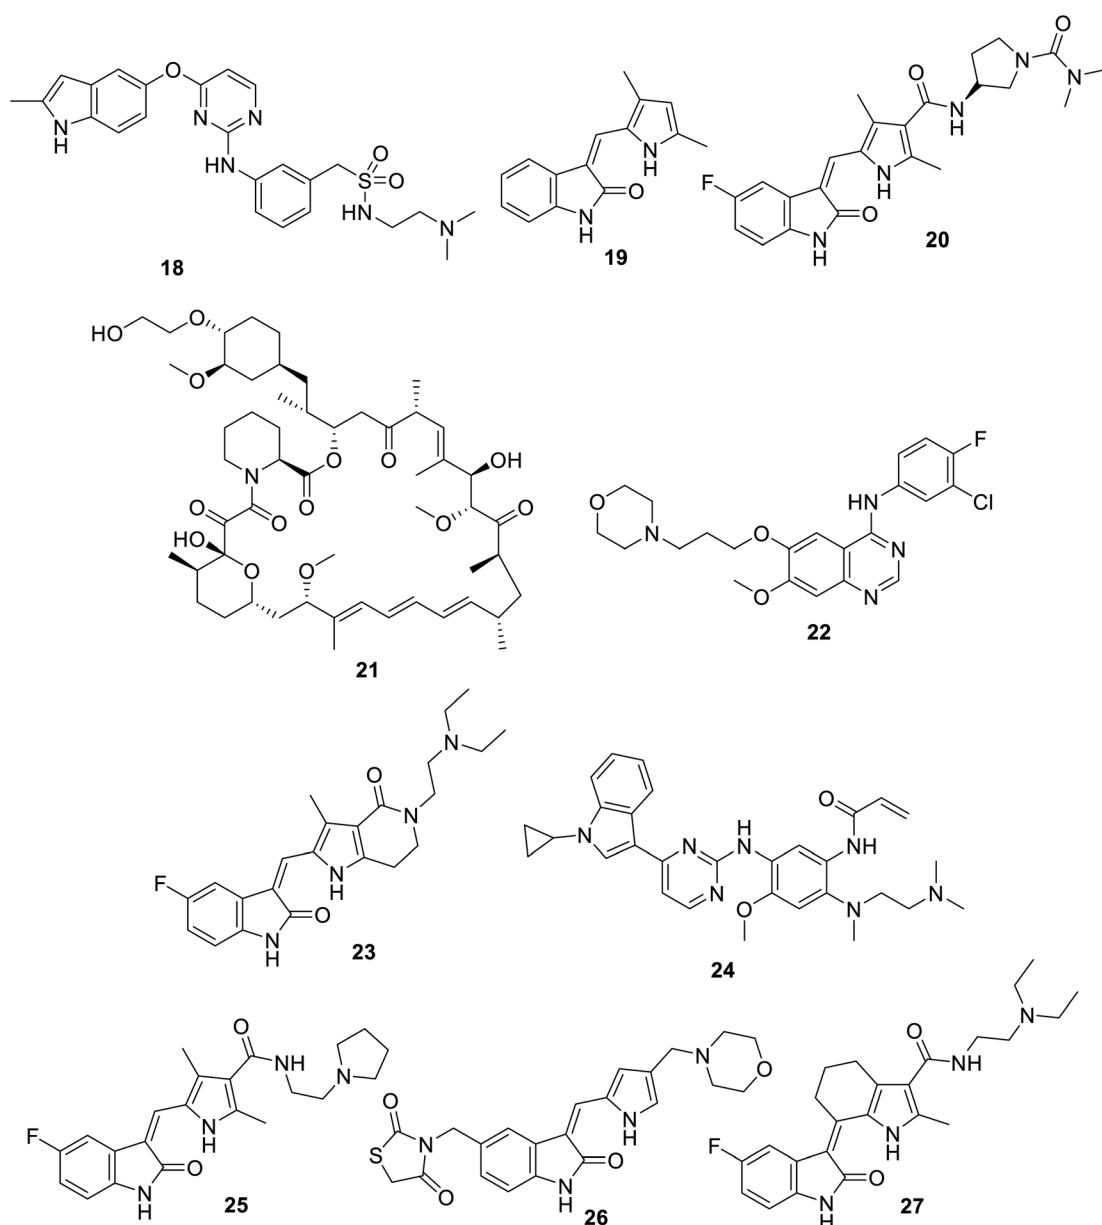

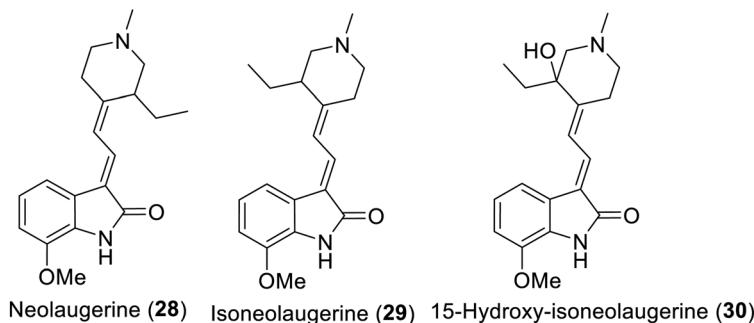

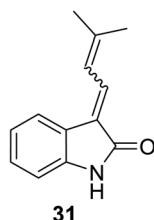

Fig. 6 Chemical structures of surufatinib 18, SU5416 (semaxanib) 19, vorolanib (CM082) 20, everolimus 21, gefitinib (Iressa) 22, famitinib 23, almonertinib (HS-10296) 24, toceranib (Palladia, Zoetis) 25, S49076 26 and SIM010603 27.

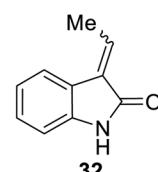

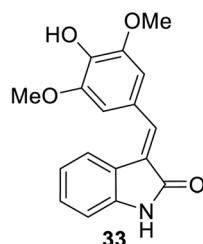

Three oxindole alkaloids were isolated from the root bark of *Neolaugeria resinosa*, a small evergreen tree distributed throughout the Bahamas and West Indies

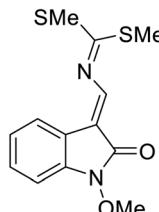

(E)- and (Z)-3-(3'-methyl-2'-butenylidene)-2-indolinones, these two yellow pigments were isolated from the rhizomes of *Cimicifuga dahurica*, a plant used in the Chinese traditional medicine and particularly known for its antipyretic properties

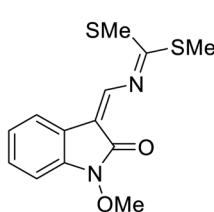

(E)- and (Z)-3-ethylidene-1,3-dihydroindol-2-ones were isolated from the fungus *Colletotrichum fragariae* and have been described as self-germination inhibitors

The oxindole alkaloid *E*-was isolated from the roots of *Isatis indigotica*, a constituent of the widely used traditional Chinese medicine mainly used for its antipyretic, antiviral and detoxifying properties

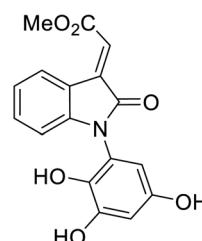

Wasalexin A (34)

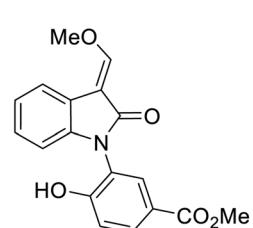

Wasalexin B (35)

Two phytoalexins were isolated from the foliar tissue of wasabi (*Wasabia japonica*, *syn. Eutrema wasabi*) and wasalexin A exhibited antifungal activity against *Phoma lingam*

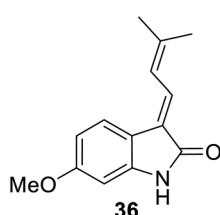

Costinone A (37)

Costinone B (38)

Costinone A and costinone B were isolated from the Pakistani herb *Isatis costata* and found to inhibit lipoxygenases and butylcholinesterases

Soulieotine was isolated from the rhizomes of *Souliea vaginata*, a plant employed as an anti-inflammatory analgesic in traditional Chinese medicine.

Fig. 7 Natural indole-containing compounds 28–38 with potential bio-properties.

lung disease (2019) and NSCLC (in combination with docetaxel 13).^{50,52–56} However, the most notable side effects are diarrhea and increase in alanine and aspartate aminotransferase associated with the clinical administration of nintedanib.⁵⁴

Many studies explained the promising efficacy of nintedanib against different types of cancer. The delay of the proliferation and growth arrest of a mouse prostate (TRAMP: transgenic adenocarcinoma of the mouse prostate) model by nintedanib

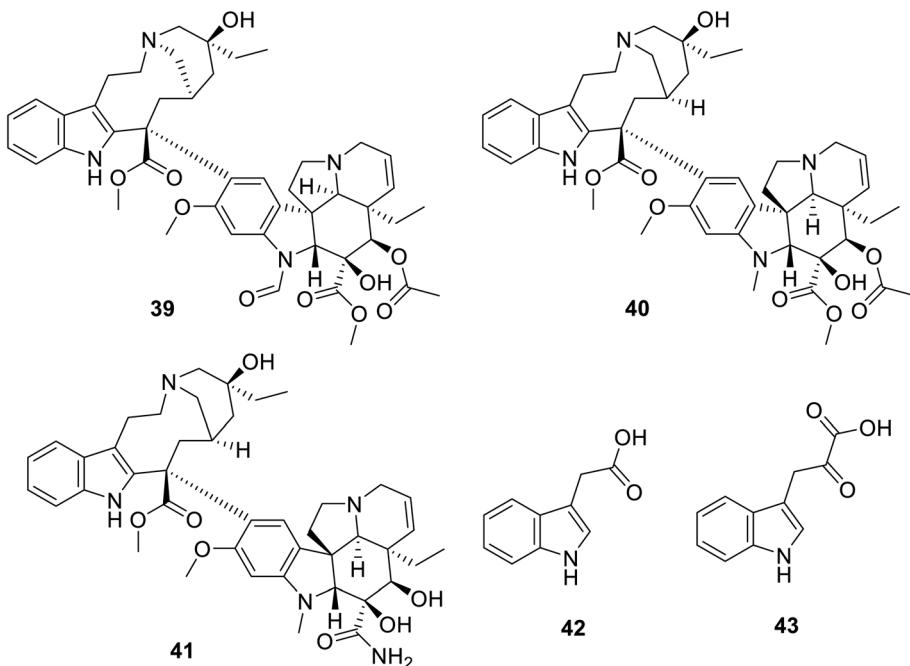

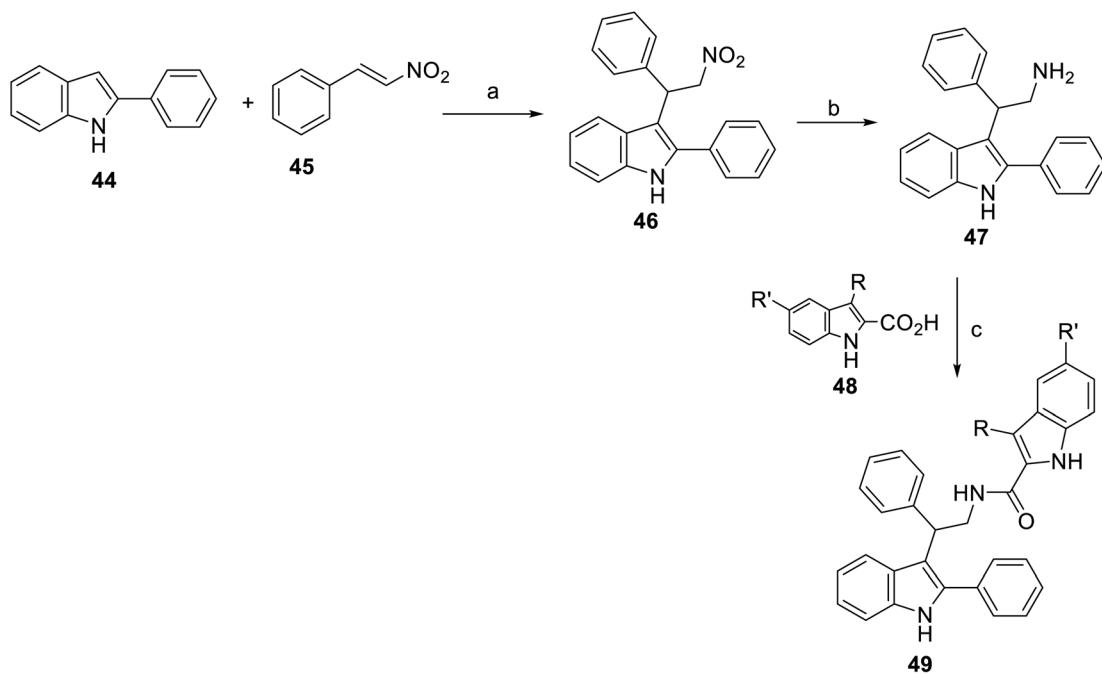

Fig. 8 Chemical structures of vincristine 39, vinblastine 40, vindesine 41, 3-indole acetic acid 42 and 3-indole pyruvic acid 43.

indicates its promising properties against prostate cancer.^{57,58} Its clinical trial (phase III) also support its promising properties against ovarian cancer.^{59,60} A compensatory role was reported for nintedanib towards metastatic colon cancer.⁶¹ Meanwhile, clinical trial observation (20 patients, 200 mg twice per day)

revealed that there was no considerable effect on salivary gland cancer except in controlling the rate of the disease.⁶² A phase I clinical study (13 elderly patients) also showed its efficacy towards myeloid leukemic cells, especially when used with cytarabine 14.⁶³

2.3. Anlotinib

Anlotinib 15 (Fig. 5) is an oral multi-targeted tyrosine kinase inhibitor (VEGFR, PDGFR, FGFR and c-kit) approved in China for NSCLC.^{64–69} Hypertension and gastrointestinal problems are the most significant side effects associated with its administration.⁶⁵ Finger print loss for about two months was observed during a case study on its treatment of lung cancer.⁶⁵ It has also been

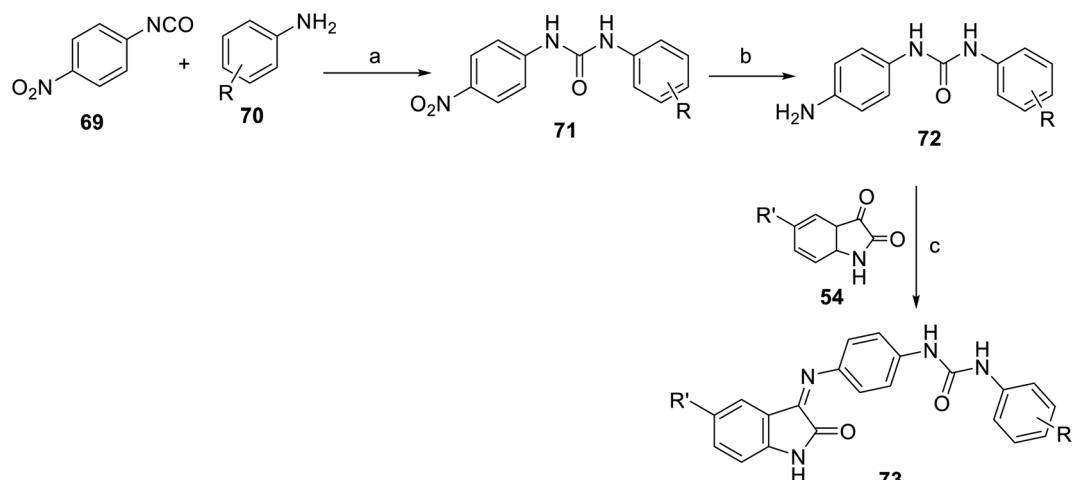

reported that anlotinib is capable of inhibiting lymphangiogenesis and lymphatic metastasis, which is probably due to the suppression of VEGFR-3 phosphorylation.⁷⁰ Antiproliferation properties were also observed against colon cancer cells (HCT-116 and LOVO).⁷¹ Moreover, anlotinib showed promising properties against thyroid and metastatic renal cell cancers.^{68,72} A phase II clinical study supported the possibility for the therapeutic

utilization of anlotinib in combination with oxaliplatin **16** and capecitabine **17** to treat patients with metastatic colon cancer.⁷³

2.4. Surufatinib (HMPL-012, sulfatinib)

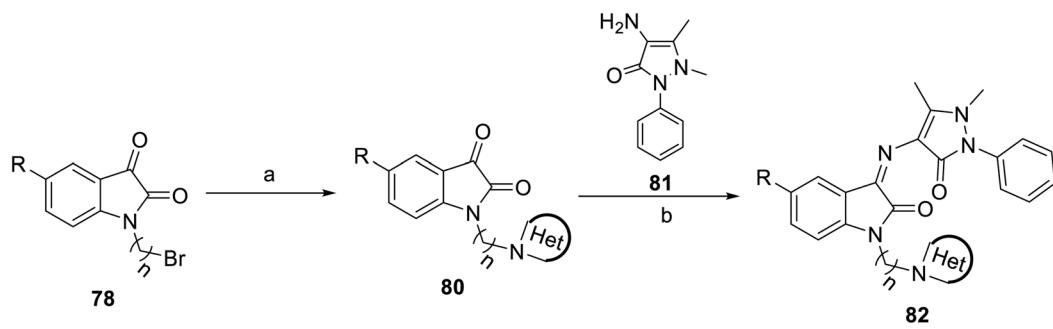

Surufatinib (Sulanda) **18** (Fig. 6) is an oral multi-kinase inhibitor with dual function against angiogenesis (VEGFR-1, -2, -3 and FGFR) and tumor immune evasion (CSF-1R: colony

stimulating factor-1 receptor). It is approved (in China, 2020) for the treatment of extrapancreatic neuroendocrine tumor (NET).⁷⁴ However, it has been filed with the FDA for approval for the treatment of advanced NET (2021).⁷⁵ Hypertension and proteinuria are the most severe adverse effects reported with the administration of Sulanda.⁷⁶ A phase II clinical study adopting 39 patients (300 mg, 28 day cycles, once daily) supported its possibility for moderate biliary tract cancer.⁷⁷

2.5. SU5416 (semaxanib)

SU5416 (semaxanib) **19** (Fig. 6) is a human solid tumor anti-angiogenic VEGFR inhibitor under investigation.⁷⁸⁻⁸⁰ Its anti-proliferation of murine cardiac endothelial cells was reported.⁸⁰ Also, pathophysiological effects in respiratory disorders were mentioned, which was supported by the lipopolysaccharide-induced acute lung injury in mice *via* restrain/modulate vascular permeability.⁷⁹

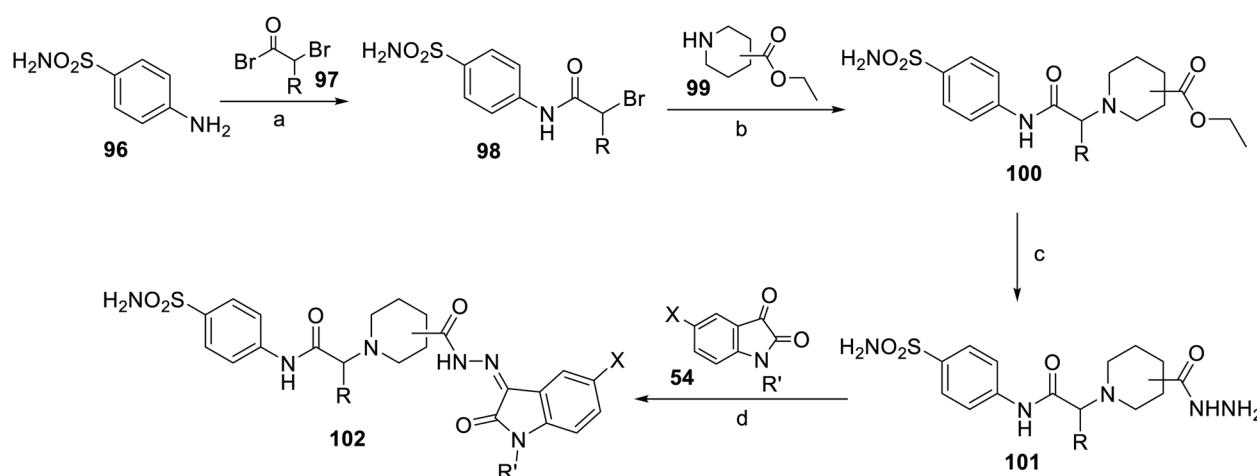

2.6. Vorolanib

Vorolanib (CM082) **20** (Fig. 6) is an oral VEGFR and PDGFR inhibitor.⁸¹ A phase I study (22 patients) exhibited promising results for the combination of vorolanib with everolimus **21**

towards renal and neuroendocrine cancers.⁸² It has also mentioned that vorolanib enhances the antiproliferation and apoptosis properties of gefitinib (Iressa) **22** (EGFR: epidermal growth factor receptor, inhibitor) towards NSCLC cell lines (HCC827 and H3255). This was explained by the strong inhibitory properties of the combined therapeutics on STAT3 phosphorylation compared to that of the mono-therapeutic.⁸³

2.7. Famitinib

Famitinib **23** (Fig. 6) is an oral VEGFR-2 and -3 inhibitor used in trial studies against colon and renal cancers.^{84,85} A promising synergistic effect was observed against NSCLC upon the combination of famitinib with almonertinib (HS-10296, EGFR inhibitor) **24**.⁸⁵

2.8. Toceranib

Toceranib (Palladia, Zoetis) 25 (Fig. 6) is a multi-targeted tyrosine kinase inhibitor (VEGFR-2, PDGFRs and c-Kit) used as a phosphate salt for the treatment of bone cancer (canine

osteosarcoma) in veterinary medicine (dogs). Cell growth inhibition of toceranib phosphate on canine osteosarcoma (Penny and Wall) *in vitro* was reported.⁸⁶

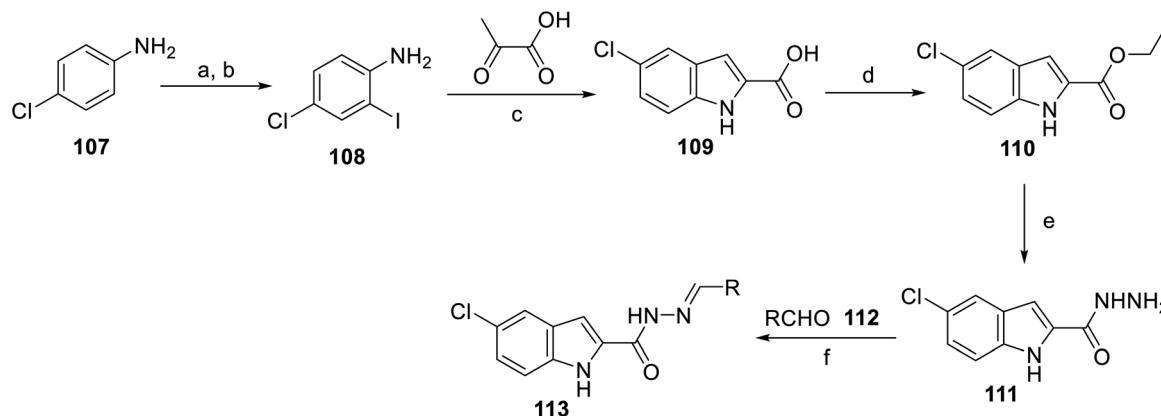

R = H, Me; R' = 4-HOC₆H₄, 4-BrC₆H₄, 4-FC₆H₄, 4-CIC₆H₄, 4-NO₂C₆H₄, 4-Me₂NC₆H₄, 2-furanyl, 3,4,5-(MeO)₃C₆H₂, 4-C₆H₄OCH₂Ph, 2-pyrrolyl, 1-benzyl-2-oxoindolinyl

2.9. S49076

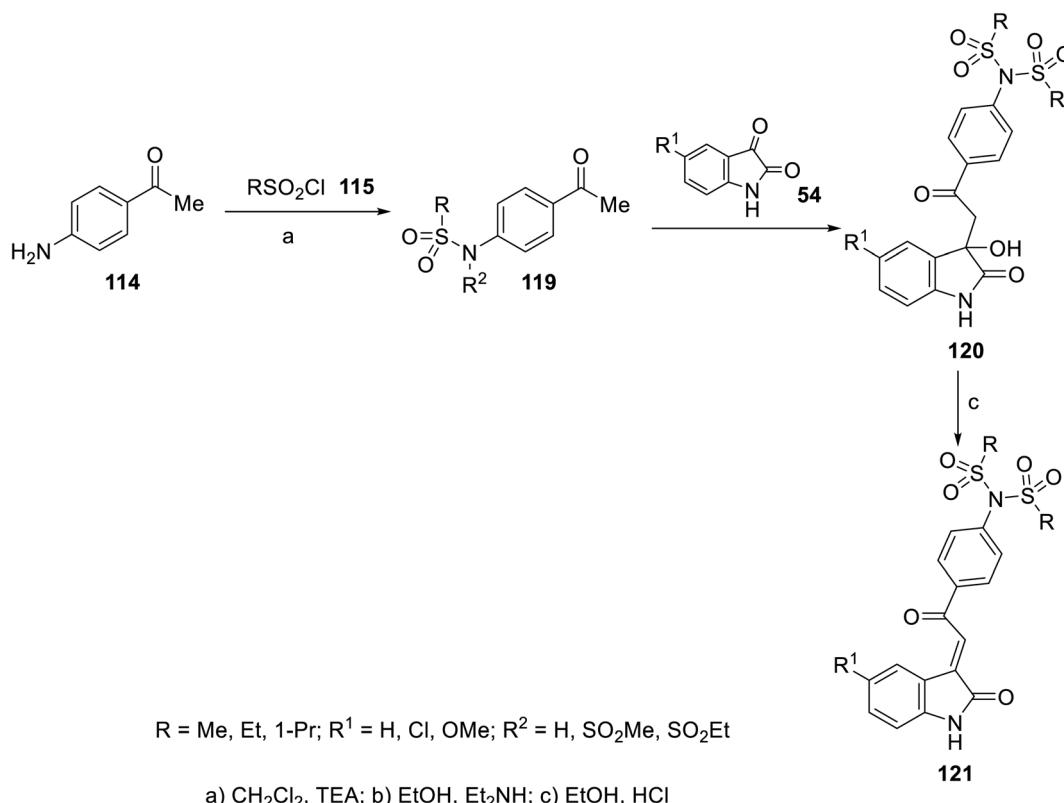

S49076 26 (Fig. 6) is a VEGF and HIF-1- α (hypoxia-inducible factor 1-alpha) inhibitor.⁸⁷ The inhibition of VEGF and HIF-1 expression can explain the mode of action of S49076 in ovarian cancer cells.⁸⁷ The administration of S49076 as a monotherapeutic resulted in the arrest of colon bevacizumab-

resistant tumor growth. Moreover, the combination of S49076 and bevacizumab (Avastin, anti-vascular endothelial growth factor antibody) showed total growth inhibition of colon cancer xenograft models.⁸⁸ A phase I study (103 patients) also revealed its effect on solid tumors (colon, lung, mesothelioma and uveal melanoma) upon oral administration.⁸⁹

Scheme 16 Synthesis of 2-oxoindolin-3-ylidene 124.

2.10. SIM010603

SIM010603 27 (Fig. 6) is an oral multi-targeted tyrosine kinase inhibitor (VEGFR-2, -3; PDGFR- β and stem cell factor receptor “c-kit”).⁹⁰ Antiproliferation properties were reported against NCI-H460 (human lung), LLC-SW44 (Lewis lung) and MDA-MB-435 (breast) cancer cells in addition to the inhibition of xenograft tumor growth models and angiogenesis in mice.⁹⁰ Adverse effects including gastrointestinal, pancreatic and skeletal toxicities, bronchopneumonia and cardiovascular dysfunction were mentioned in the toxicological studies of SIM010603 in rats and dogs (0–20 and 0–10 mg kg^{-1} per day oral administration,

respectively, for 28 followed by 14 recovery days). However, no mortality rates were recorded for dogs receiving 10 mg kg^{-1} .⁹¹

3. Natural indole-containing compounds

Many natural indolyl derivatives have been identified to possess considerable bio-properties including 28–38, as summarized in Fig. 7.⁹² Vincristine 39 (Fig. 8) was isolated from *Vinca rosea* and approved by the FDA (since 1963) for the treatment of Hodgkin's disease, non-Hodgkin's lymphoma and neuroblastoma.^{93–95}

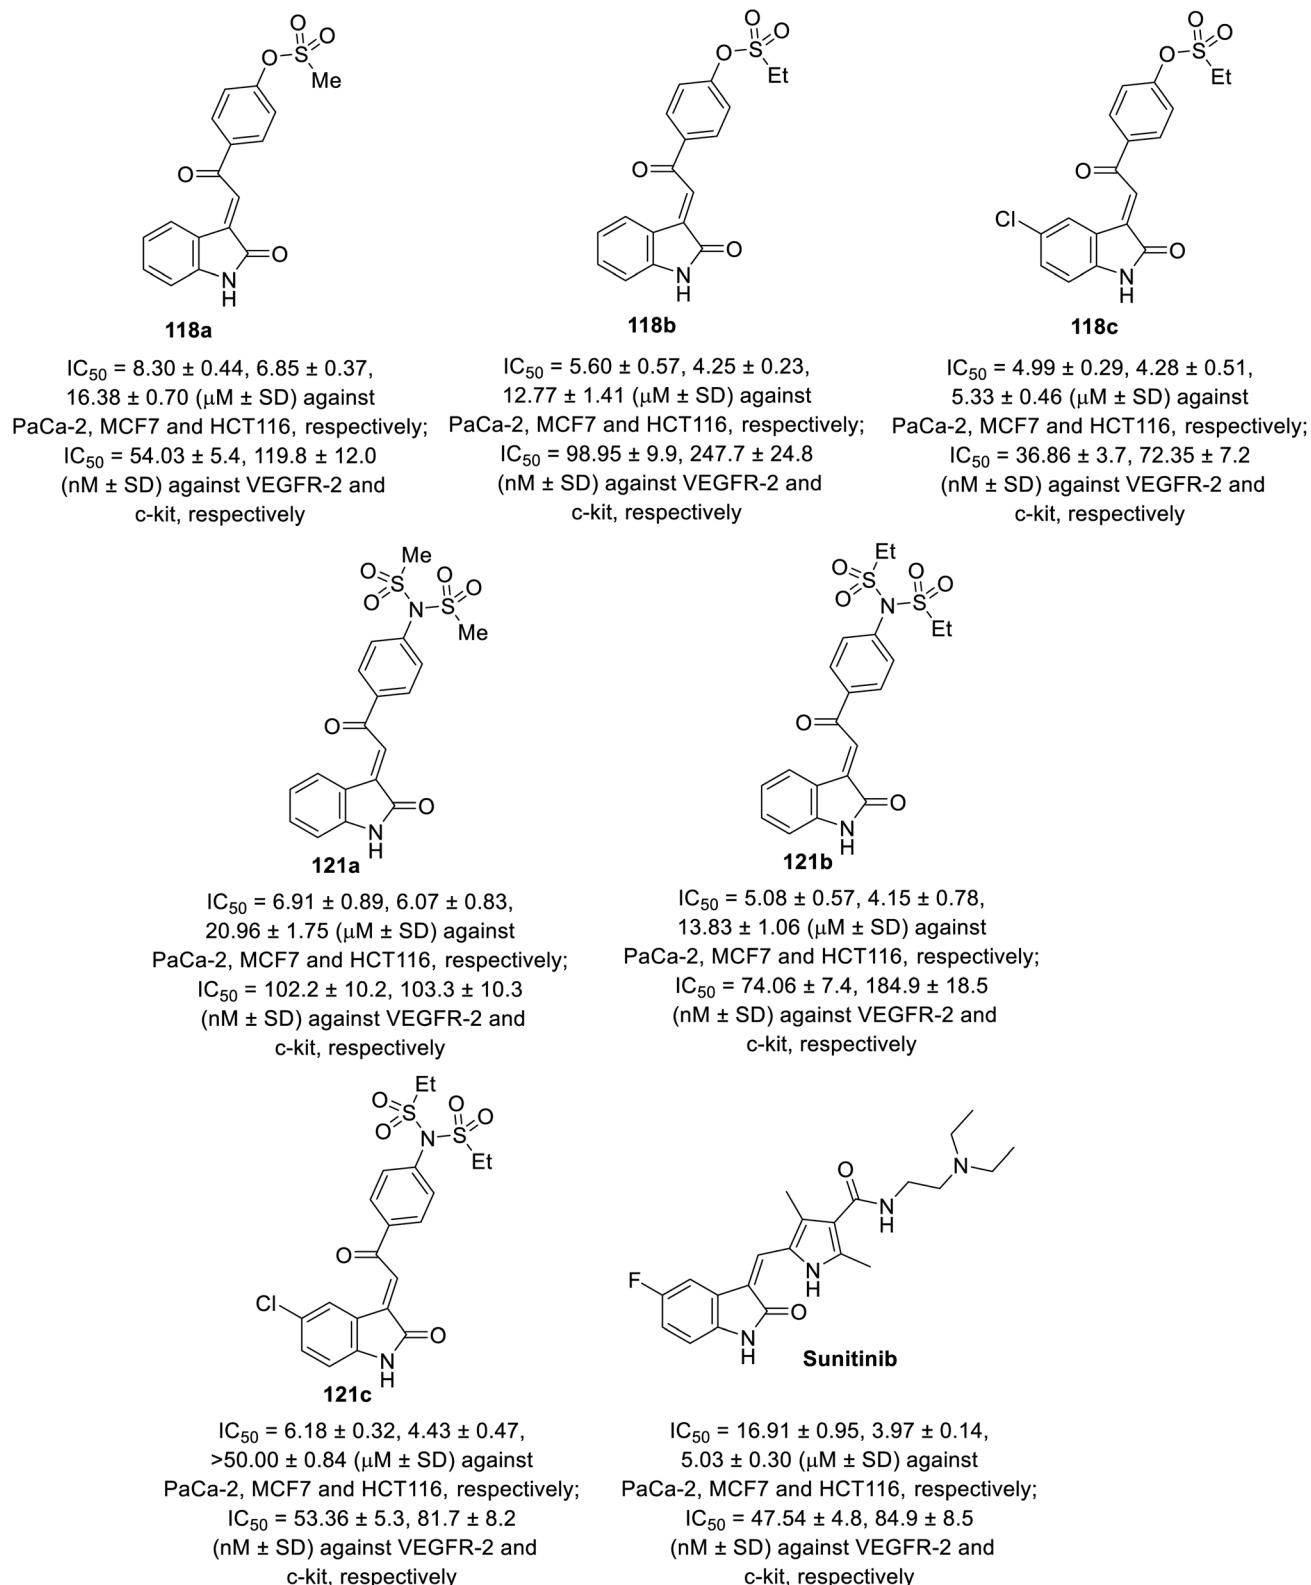

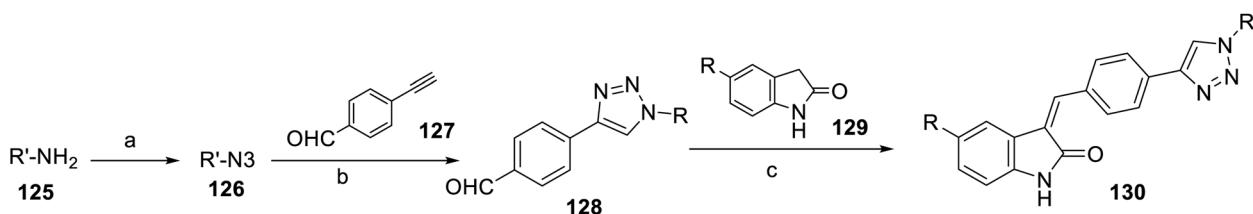

Fig. 10 Antiproliferation and tyrosine kinase (VEGFR-2, c-kit) inhibitory properties of 118a-c, 121a-c and sunitinib.

Vinblastine (Velban) **40** is also a *Vinca* alkaloid approved by the FDA (since 1965) for the treatment of Hodgkin's disease, lymphoma, and testicular and breast cancers.⁹⁵⁻⁹⁷ Vindesine (Eldisine) **41** is a *Vinca* alkaloid with efficacy against acute

lymphocytic leukemia.^{95,98} 3-Indole acetic acid **42**, which is present in wine, and 3-indole pyruvic acid **43** (human metabolite) exhibited inhibitory properties against VEGFR-2 with $IC_{50} = 0.9704$ and 1.037 mM , respectively⁹⁹ (Fig. 8).

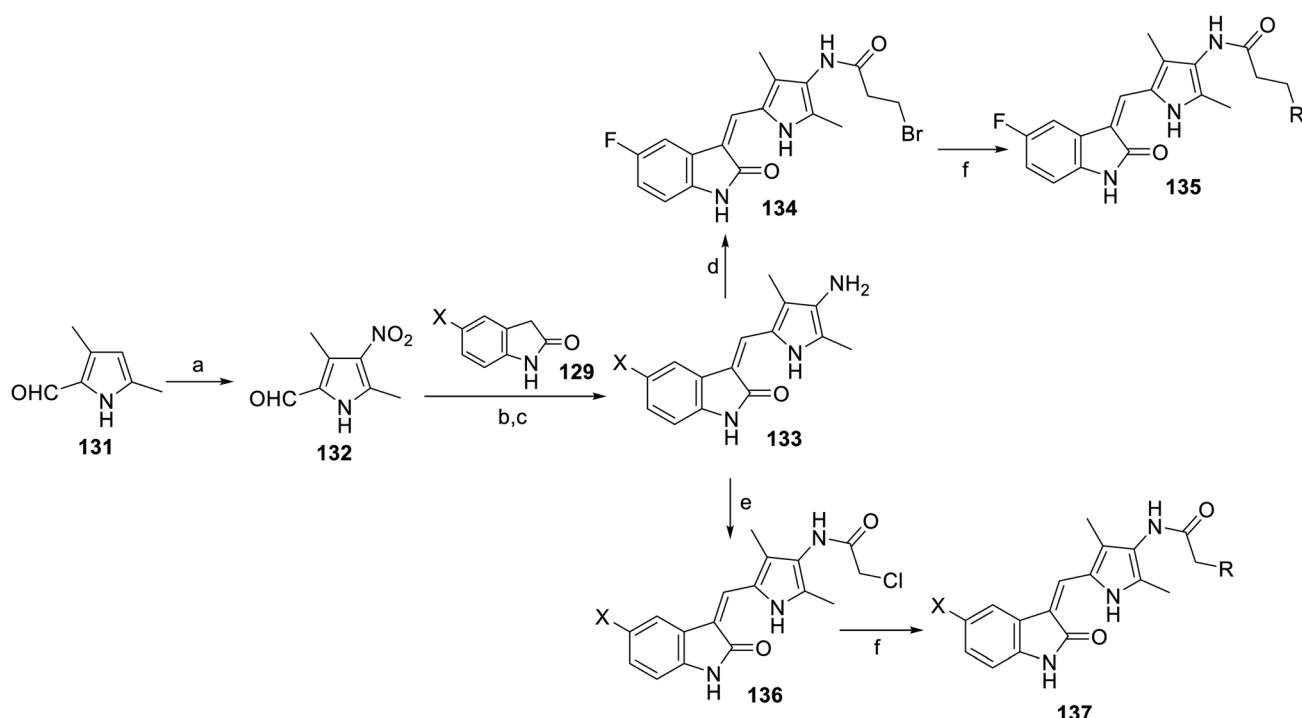

R = H, F; R' = Ph, 2-MeC₆H₄, 3-MeC₆H₄, 4-MeC₆H₄, 2-FC₆H₄, 3-FC₆H₄, 4-FC₆H₄, 2-CIC₆H₄, 3-CIC₆H₄, 4-CIC₆H₄, 2-NCC₆H₄, 3-NCC₆H₄, 4-NCC₆H₄, 3-Cl-4-CF₃C₆H₃

4. Synthesized indole-containing compounds

4.1. Indolecarboxamide

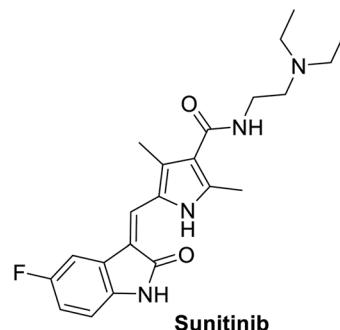

A variety of indole-2-carboxamides **49** was synthesized through the reaction of 2-(1*H*-indol-3-yl)ethan-1-amine **47** with 2-indolecarboxylic acids **48** in DCM (dichloromethane) containing

BOP (benzotriazol-1-yloxytris(dimethylamino)phosphonium hexafluorophosphate) and DIPEA (diisopropyl ethylamine). Compound **47** was obtained through the reduction of nitro analog **46** by LiAlH₄ in Et₂O (at 0 °C to room temperature) under an inert (nitrogen) atmosphere. The latter **46** was synthesized by the addition reaction of 2-phenylindole **44** to β-nitrostyrene **45** in refluxing MeOH containing sulfamic acid¹⁰⁰ (Scheme 1). Greater antiproliferation properties against a variety of human

IC_{50} = 0.008, 0.07, 6.11, 20.61, 17.08, 14.71, 6.85, 41.38 μ M against MV4-11, TT, NCI-H460, H526, H3122, Bel7402, HK-2, LO2, respectively; K_i = <0.0003, 0.0038, 0.019, 1.1, 0.2 μ M against FLT4 (VEGFR-3), KDR (VEGFR-2), PDGFR- β , VEGFR-1 and c-kit, respectively.

IC_{50} = 0.003, 0.04, 4.31, 1.01, 0.83, 2.67, 5.85, 19.93 μ M against MV4-11, TT, NCI-H460, H526, H3122, Bel7402, HK-2, LO2, respectively; K_i = 0.017, 0.009, 0.008, 0.002, 0.004 μ M against FLT4 (VEGFR-3), KDR (VEGFR-2), PDGFR- β , VEGFR-1 and c-kit, respectively.

Fig. 11 Antiproliferation and receptor inhibitory properties of **138** and sunitinib.

tumor cell lines [MTT: 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assay, Panc-1 (pancreatic), MCF7 (breast), HT-29 (colon) and A-549 (epithelial)] were revealed (IC_{50} , nM \pm SEM “standard error mean”) for some of the prepared 2-indolecarboxamides **49** compared to that of erlotinib. Also, mild VEGFR-2 inhibitory properties were observed by some of the derivatives of **49** relative to that of sorafenib. The most considerable agent was **49e** ($R = \text{CH}_2\text{OH}$, $R' = \text{Cl}$; $IC_{50} = 44 \pm 4$, 46 ± 4 , 45 ± 4 , and 42 ± 4 nM against Panc-1, MCF7, HT-29 and A-549, respectively; $IC_{50} = 1.10 \pm 0.08$ nM against VEGFR-2) (ESI Fig. S1†). Based on the observed anti-proliferation properties, it was concluded that the function/group at the 3-position of the indole-2-carboxamide is the dominant factor, with the bio-properties following the order of H > methoxyvinyl > ethoxymethyl > hydroxymethyl > phenyl.¹⁰⁰

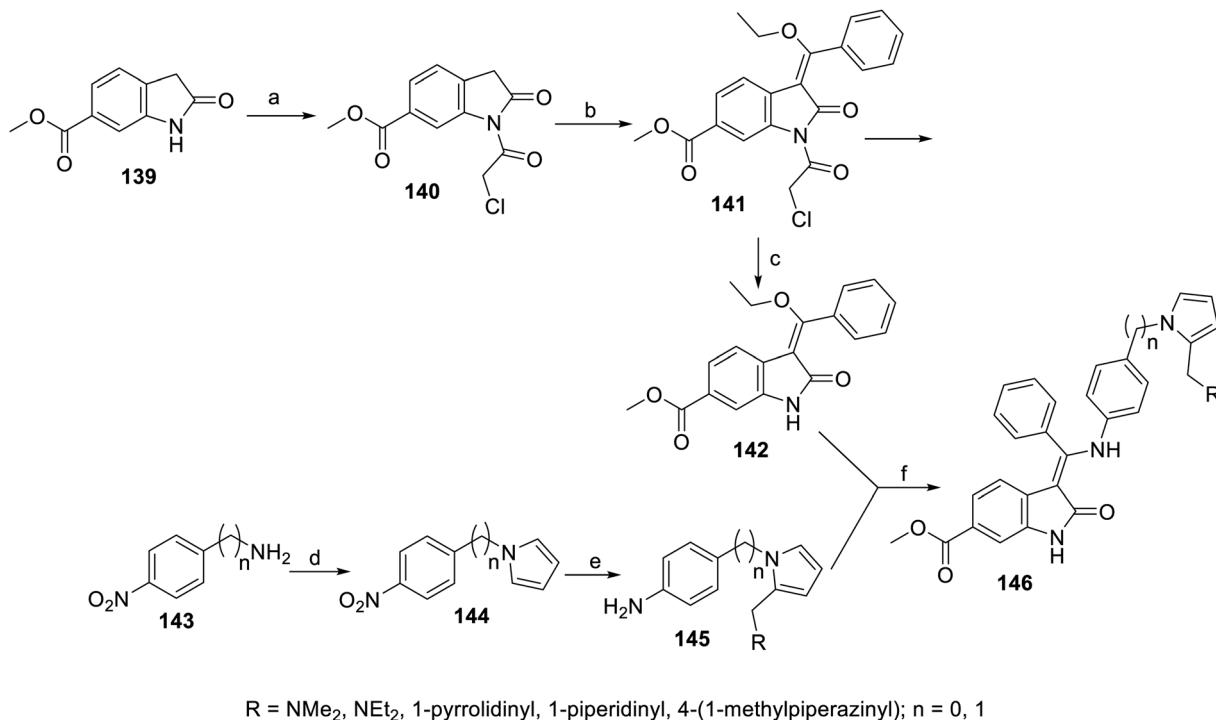

A set of 5-indolecarboxamides **53** was obtained through the reaction of the corresponding amino analogs **52** with the appropriate carboxylic acid in the presence of Hünig's base (*N,N*-diisopropylethylamine “Hünig's base”, DIPEA) using HATU (hexafluorophosphate azabenzotriazole tetramethyl uronium, coupling agent). 5-Aminoindoles **52** were prepared through the reduction of nitro analogs **51** (Fe, NH_4Cl , EtOH/ H_2O). The latter **51** was obtained through the alkylation of 5-nitroindole **50**^{101,102} (Scheme 2). Weak VEGFR-2, CDK-1/cyclin B (cyclin-dependent kinase 1), and HER-2 (human epidermal growth factor receptor 2) properties were exhibited by most of

the synthesized agents **53** at 10 μ M. However, compound **53l** [$R = \text{CO}(3\text{-FC}_6\text{H}_4)$, $R' = 4\text{-pyridazinyl}$] revealed promising kinase inhibitory activity against CDK-1/cyclin B and HER-2 (activity = 51% and 52%, respectively) at 10 μ M¹⁰¹ (ESI Fig. S2†).

4.2. Indolyl Schiff bases

Condensation of isatins **54** with *p*-aminobenzoic acid (in refluxing EtOH containing a catalytic amount of AcOH) resulted in the formation of Schiff bases **55**, which upon reaction with 4-methylthiosemicarbazide **56** afforded the corresponding semicarbazones **57**. Similarly, the reaction of isatins **54** with benzocaine (4-aminobenzoic acid ethyl ester) **58**, followed by reaction with hydrazine hydrate in refluxing ethanol gave the corresponding hydrazides **59**. The latter were subjected to reaction with aromatic aldehydes **60** (in refluxing EtOH containing a catalytic amount of AcOH), ethyl acetoacetate **62** (in EtOH/AcOH, under sonication at 50 °C), phthalic anhydride **64** (in AcOH “glacial” under sonication at 50 °C) or phenyl isothiocyanate **66** (in refluxing EtOH), yielding the corresponding hydrazone **61**, **63**, dioxoisindoline **65** and thiourea derivatives **67**, respectively. Reaction of **59** with carbon disulfide in refluxing ethanolic KOH followed by acidification with HCl (10%), afforded the corresponding oxadiazolyl derivatives **68** (Scheme 3).

Some of the synthesized agents exhibited promising anti-proliferation properties against HepG2 (liver) and MCF7 (breast) cancer cell lines relative to that of sunitinib (MTT assay;

a) chloroacetic anhydride, PhMe, reflux, 3 h; b) PhMe, Ac_2O , triethyl orthobenzoate, reflux, 5 h; c) KOH, MeOH, 25 °C, 20 min; d) NaOAc, 2,5-dimethoxytetrahydrofuran, AcOH, 75 °C, 3–5 h; e) (i) paraformaldehyde, appropriate amine, AcOH, 35 °C, 6–8 h; (ii) Pd/C, EtOH, 25 °C, 4 h; f) MeOH, reflux, 5–8 h.

Scheme 19 Synthesis of 2-oxoindolin-3-ylidenes 146.

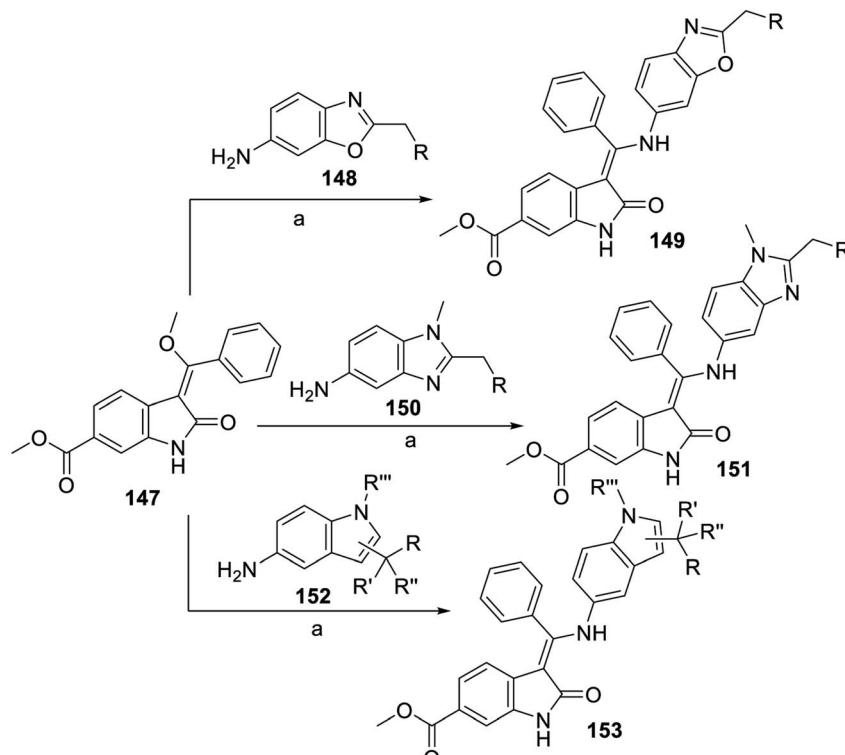

IC_{50} , $\mu\text{M} \pm \text{SD}$ “standard division”) (ESI Fig. S3†). Some of the synthesized fluorinated analogs showed enhanced antitumor properties compared to other prepared derivatives, directing attention on the importance of this substituent in controlling the bio-properties. The VEGFR-2 inhibitory properties determined for the discovered promising agents were consistent with the observed antitumor properties. Compound 67a ($\text{X} = \text{H}$) revealed promising antiproliferation and enzymatic inhibitory properties ($\text{IC}_{50} = 1.13 \pm 0.06, 1.44 \pm 0.11 \mu\text{M}$ against HepG2 and MCF7, respectively; $\text{IC}_{50} = 0.078 \pm 0.003 \mu\text{M}$ against VEGFR-2) relative to that of sunitinib ($\text{IC}_{50} = 2.23 \pm 0.11, 4.77 \pm 0.29 \mu\text{M}$ against HepG2 and MCF7, respectively; $\text{IC}_{50} = 0.139 \pm 0.007 \mu\text{M}$ against VEGFR-2)¹⁰³ (ESI Fig. S3†).

A set of indolyl Schiff bases incorporated in urea 73 was synthesized through the condensation reaction of the appropriate indoles 54 with the corresponding 1-(4-aminophenyl)-3-substituted urea 72. The latter was obtained through reduction (H_2 , Pd/C, and MeOH) of the corresponding nitro analogs, which were prepared through reaction of 4-nitrophenylisocyanate 69 with the appropriate anilines 70 in refluxing acetonitrile¹⁰⁴ (Scheme 4). Some of the synthesized Schiff bases revealed promising antiproliferation properties (SRB “sulforhodamine B” technique) against the HepG2 (liver) cancer cell line relative to that of doxorubicin and sorafenib. The VEGFR-2 properties were determined for the discovered promising agents, which showed comparable observations to that of the antiproliferation efficacies. The efficacy observed for

most of the synthesized agents followed order of phenyl substitution of 4-Cl > 3-Cl > 3-CF₃. The most promising agent discovered was 73x ($\text{R} = \text{SO}_2\text{NH}_2$, $\text{R}' = \text{Cl}$; $\text{IC}_{50} = 3.15 \pm 0.36$ and $0.31 \pm 0.04 \mu\text{M}$ for HepG2 cell line and VEGFR-2, respectively), which exhibited comparable activity to that of sorafenib ($\text{IC}_{50} = 3.40 \pm 0.25$, $0.10 \pm 0.02 \mu\text{M}$ for the HepG2 cell line and VEGFR-2, respectively)¹⁰⁴ (ESI Fig. S4†).

The condensation reaction of isatins 54 with L-phenylalanine secondary amine conjugates (obtained from the reaction of Boc amino acid with secondary amines in THF (tetrahydrofuran) in the presence of IBCF (iso-butyl chloroformate) and NMM (*N*-methyl morpholine) at room temperature and inert atmosphere followed by removal of the Boc group (HCl_{gas} in dioxane)) in EtOH containing triethylamine (TEA) at room temperature gave the corresponding Schiff bases 76 (Scheme 5). Additionally, the reaction of isatins 79/80 with 4-amino antipyrine 81 in ethanolic solution at room temperature afforded the corresponding Schiff bases 83 and 82, respectively. Isatin derivatives 80 were obtained through alkylation with excess dibromoalkane (DMF/ K_2CO_3), which gave monoalkylated derivatives 78 (major products) and bis-isatin derivatives 79 (minor products). The monoalkylated isatins were coupled with secondary amines (DMF/ K_2CO_3 at room temperature) affording the corresponding isatin derivatives 80 (Schemes 6–8).

Similarly, Schiff bases 88 were obtained through the condensation of 4-amino antipyrine 81 with isatin triazol conjugates 87 (EtOH, room temperature). Isatin triazol

$R = NMe_2, 4\text{-Me-1-piperazinyl}; CRR'R'' = 2\text{-NMe}_2, 2\text{-}(4\text{-Me-1-piperazinyl}), 2\text{-CONMe}_2, 2\text{-CO-(4-Me-1-piperazinyl)}, 3\text{-CH}_2NMe_2, 3\text{-CH}_2\text{-}(4\text{-Me-1-piperazinyl}), 3\text{-CH}_2\text{-}(4\text{-morpholinyl}); R''' = H, Me, Et, i\text{-Pr}$

a) MeOH, reflux, 5–10 h

Scheme 20 Synthesis of 2-oxoindolin-3-ylidene 149, 151 and 153.

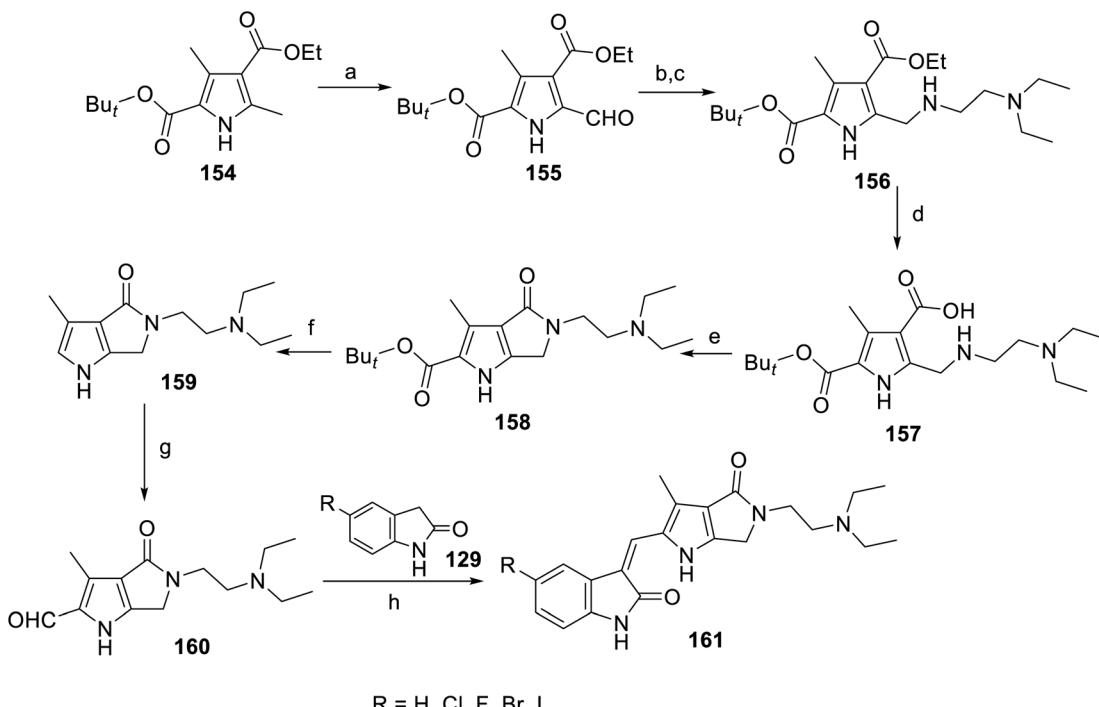

conjugates 87 were synthesized through the click reaction of the appropriate aryl azides 86 with *N*-propargylated isatins 85 (*t*-butanol/H₂O, CuSO₅·5H₂O, sodium *D*-isoascorbate, microwave, 100 °C)¹⁵ (Scheme 9).

Some of the synthesized Schiff bases exhibited promising antiproliferation properties against MCF7 (breast), HCT116 (colon) and PaCa2 (pancreatic) cancer cell lines (MTT assay) compared to the reference standards (sunitinib and 5-fluorouracil) (ESI Fig. S5†). Compound 88f (R = Me, R¹ = H, and R² = OMe) was the highest potent analog observed against MCF7 (2.1-times potency relative to the standard reference sunitinib). Additionally, some of the compounds prepared (88b, 88d and 88f) exhibited higher efficacies than that of the standard drug 5-fluorouracil (approved drug for colon cancer¹⁰⁵). The safe profile of all the tested analogs (IC₅₀ = >50.00 μM) against the non-cancer RPE1 cell line is good support, especially for the high potent analogs towards more detailed studies for assigning promising hits. The CAM assay (chick chorioallantoic membrane) of fertilized chicken eggs in addition to VEGFR-2 inhibitory properties (% inhibition ± SD utilizing the IC₅₀ values observed against MCF7 cell line of the tested agents relative to that of sunitinib) (ESI Fig. S5†) support their capability towards antiangiogenesis.¹⁵

4.3. Indolyl hydrazones

An ethanolic solution of 3-indolecarbaldehyde derivative 94 and hydrazide analog 93 in the presence of a catalytic amount of acetic acid under reflux afforded hydrazone 95 (Scheme 10). Hydrazone 95 exhibited considerably higher antiproliferation properties (MTT assay) against the MCF-7 and HCT116 cell lines (IC₅₀ = 12.93 ± 0.54 and 11.52 ± 0.70 μM, respectively) compared to that of sorafenib (IC₅₀ = 4.32 ± 0.33 and 7.28 ± 0.53 μM, respectively) with a safety profile against the W138 (non-cancer) cell line. Furthermore, the VEGFR-2 inhibitory properties of 95 (IC₅₀ = 25 ± 1.29 nM) were comparable to that of the standard reference sorafenib (IC₅₀ = 35 ± 1.34 nM). This study was supported by diverse computational studies (molecular docking “PDB: 2OH4, MOE2014 software”; MD “molecular dynamics, CHARMM-GUI web server, GROMACS 2021 engine”; DFT “density functional theory, Gaussian 09” and ADMET “absorption, distribution, metabolism, excretion and toxicity; Discovery Studio 4.0”).¹⁰⁶

A series of indolyl hydrazones incorporating benzenesulfonylamides 102 was synthesized through the condensation of the appropriate isatins 54 with hydrazides 101 in refluxing ethanol containing a catalytic amount of acetic acid. Hydrazides 101 were obtained through the reaction of hydrazine hydrate with the corresponding ethyl esters 100 in refluxing ethanol

a) ceric ammonium nitrate (CAN), THF, AcOH, H₂O, 1 h; b) *N,N*-diethylethylenediamine, EtOH, room temperature, 4 h; c) NaBH₄, *p*-toluenesulfonic acid (TsOH H₂O), EtOH, 6 h; d) 1N NaOH_(aq), MeOH, 65 °C, 6 h; e) 1,1'-carbonyldiimidazole (CDI), THF (dry), 6 h; f) H₂SO₄, MeOH, reflux, 4.5 h; g) Vilsmeier reagent, CH₂Cl₂, room temperature, 5 h; h) piperidine, EtOH, room temperature, 5 h.

Scheme 21 Synthesis of 2-oxoindolin-3-ylidene 161.

(Scheme 11). Some of the synthesized hydrazones **102** revealed considerable antiproliferation activities against MDA-MB-231 and MCF7 (breast cancer cell lines) compared to that of 5-fluorouracil, and VEGFR-2 inhibitory properties compared to that of sorafenib (Fig. 9). Inhibitory properties against carbonic anhydrase (CA) *hCA*, II, IX, XII were also observed by hydrazones **102** compared to the standard reference acetazolamide.¹⁰⁷

A set of hydrazones **106a–k** was prepared through the condensation reaction of 5-bromo-2-indolecarbohydrazide **105** (obtained from the reaction of hydrazine hydrate with ethyl ester of indole derivative **104** in refluxing EtOH) with the appropriate aldehyde, ketone or isatin derivative in refluxing EtOH containing a few drops of glacial AcOH (catalytic amount) (Scheme 12). Mild antiproliferation properties were exhibited by the synthesized hydrazones **106a–k** against HepG2 (liver), HeLa (cervical) and PC3 (prostate) cancer cell lines (MTT assay) with modest VEGFR-2 inhibitory activity compared to the standard reference (sorafenib; IC₅₀ = 6.2 ± 1.1, 11.7 ± 1.3, 19.0 ± 1.2, and 15.3 ± 1.8 μM against HepG2, HeLa, PC3 and WI-38 respectively; EC₅₀ = 57.1 ± 3.0 nM ± SEM against VEGFR-2). Furthermore, the most promising agent **106e** (R=4-Me₂NC₆H₄, R'=H; IC₅₀ = 14.3 ± 2.0, 22.2 ± 2.3, 36.2 ± 3.1, and 25.9 ± 2.1 μM against HepG2, HeLa, PC3 and WI-38, respectively) was screened against WI-38 (normal lung fibroblasts; EC₅₀ = 102.6 ± 3.1 nM ± SEM against VEGFR-2) to confirm its safety index¹⁰⁸ (ESI Fig. S6†).

Similarly, 5-chloroindolyl hydrazones **113** were obtained through the reaction of the corresponding hydrazide **111** and aromatic aldehydes **112** in refluxing ethanol containing AcOH as a catalyst (Scheme 13). Considerable antiproliferation properties against HCT116 and SW489 (colon) cancer in addition to MRC-5 (non-cancer human) cell lines were exhibited by some of the synthesized hydrazones compared to the standard references (cisplatin “GI₅₀ = 7.67 ± 3.4, 4.43 ± 2.1, and 3.82 ± 1.9 μM against HCT116, SW480 and MRC-5, respectively”, sorafenib “GI₅₀ = 4.17 ± 2.5, 2.02 ± 1.2, and 30.81 ± 10.6 μM against HCT116, SW480 and MRC-5, respectively” and sunitinib “GI₅₀ = 15.84 ± 1.7, 1.09 ± 0.9, > 100 μM against HCT116, SW480 and MRC-5, respectively”) (ESI Fig. S7†). Compound **113x** (R = 2,4-(MeO)₂C₆H₃; GI₅₀ = 8.10 ± 1.8, 7.90 ± 1.3, and >100 μM against HCT116, SW480 and MRC-5, respectively) was the most promising agent synthesized. Its anti-angiogenesis effect was supported by CAM proliferation and HUVEC (human umbilical vein endothelial cell) migration.¹⁰⁹

4.4. 2-Oxoindolin-3-ylidene

The FDA approval for the use of sunitinib and nintedanib as potent multi-targeted tyrosine kinase inhibitors against many cancer types^{40,41,55,56} has inspired many researchers to utilize the 2-oxoindolin-3-ylidene scaffold for optimizing novel antitumor active agents. A variety of 2-oxoindolin-3-ylidene bearing

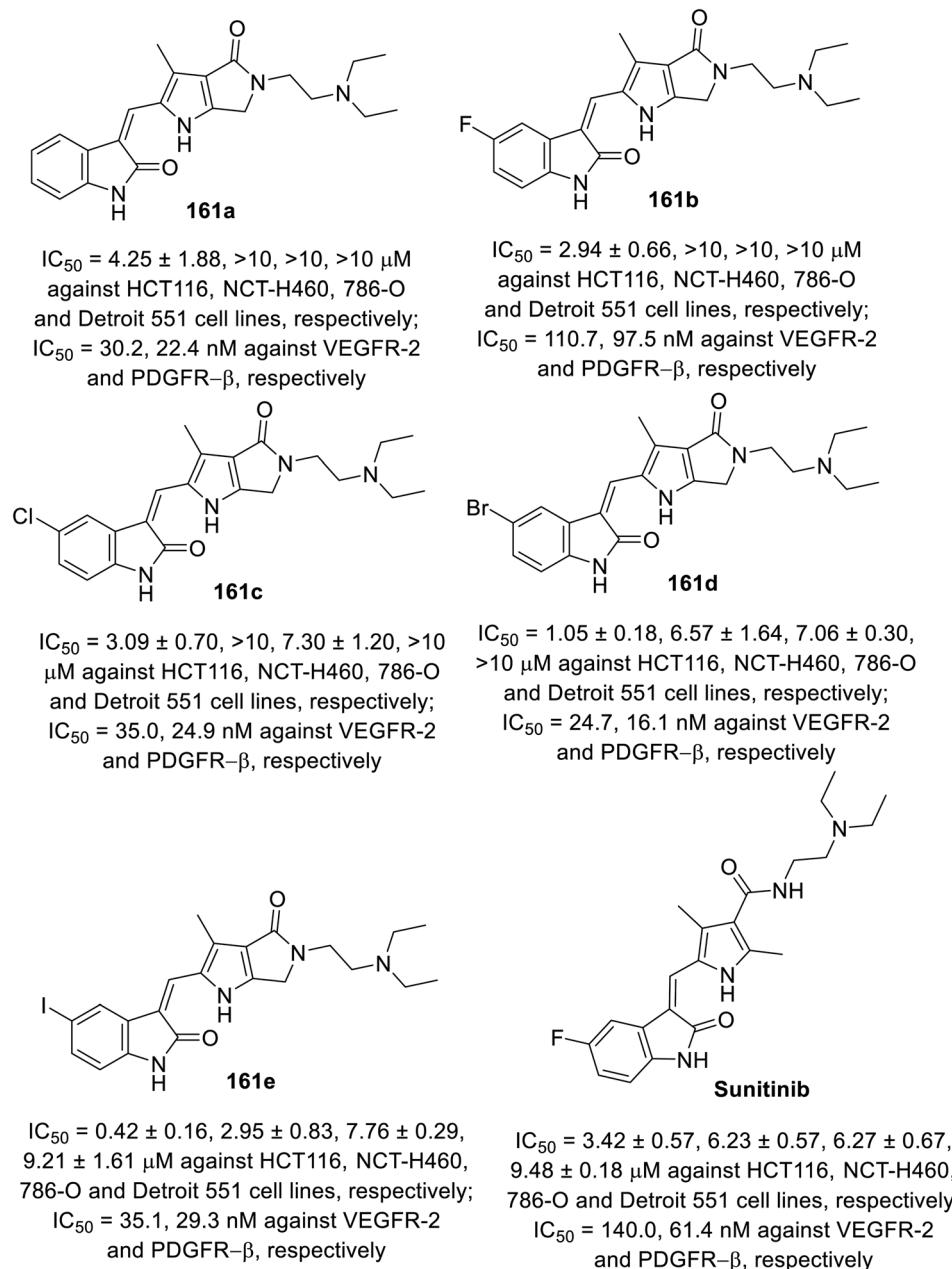

Fig. 12 Antiproliferation and enzymatic inhibitory properties of **161a–e** and sunitinib.

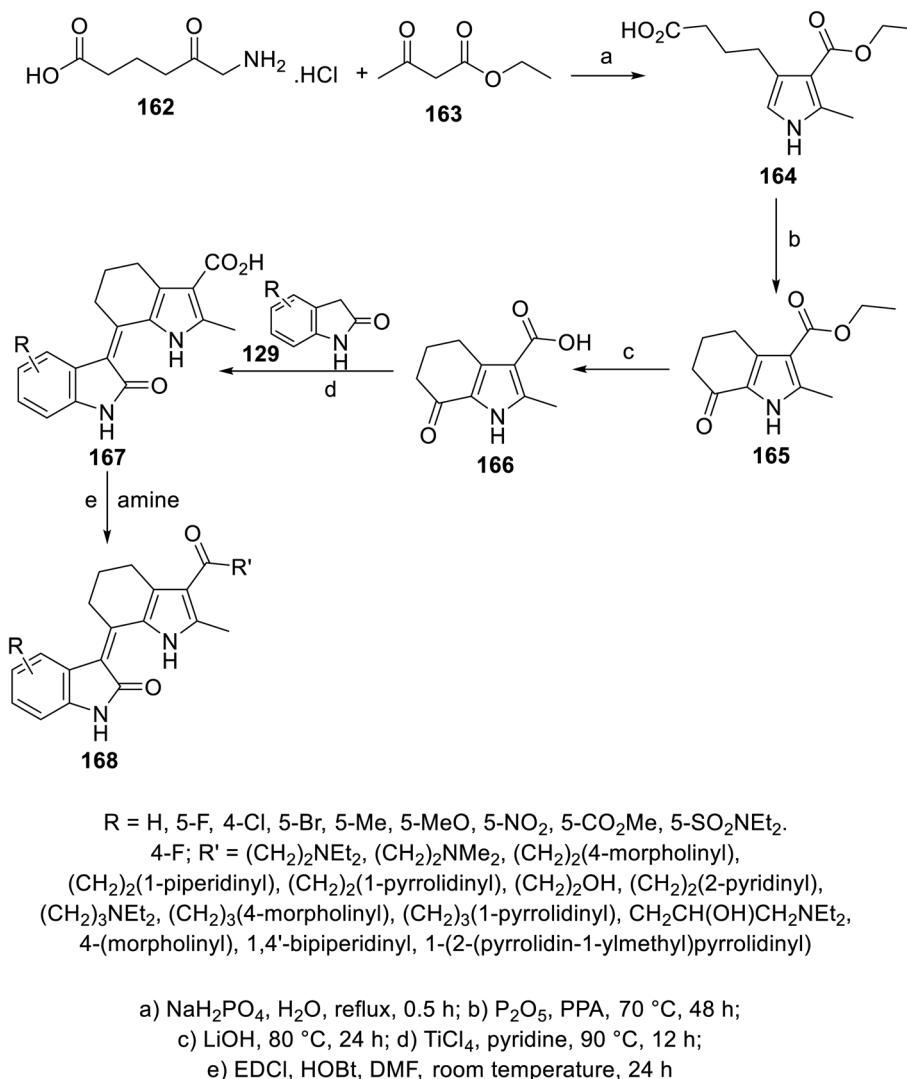

alkanesulfonate **118** was synthesized in a two-step reaction in excellent yields. The reaction of isatins **54** in EtOH containing a quantitative amount of Et₂NH gave the corresponding 3-hydroxy-2-oxoindole derivatives **117**. Acidic dehydration (EtOH and HCl) of **117** gave the corresponding **118**⁹² (Scheme 14).

2-Oxoindolin-3-ylidene incorporating alkanesulfonamide **121** were formed starting from the corresponding alkanesulfonamide derivatives **119** utilizing a similar reaction sequence. It was mentioned that the reaction of isatins **54** with **119** bearing a mono-propanesulfonamide function gave the corresponding **120**. This is presumably *via* the elimination of propylsulfonate from **119** under the applied basic condition⁹² (Scheme 15). Similarly, 2-oxoindolin-3-ylidene connected to

benzimidazolyl heterocycle **124** were prepared following the same reaction sequence utilizing 2-acetylbenzimidazoles **122**⁹² (Scheme 16).

Some of the synthesized agents **118** and **121** exhibited anti-proliferation properties (MTT assay) against PaCa-2 (pancreatic), MCF7 (breast) and HCT116 (colon) cancer cell lines with potency comparable to that of sunitinib. The safety index of the tested agents was established through screening against the RPE1 (retinal pigment epithelium) normal cell line. The inhibitory properties of the tested agents against VEGFR-2 and c-kit were comparable to that of the antiproliferation results (Fig. 10). Their anti-angiogenesis properties were also supported by the CAM assay.⁹²

Scheme 22 Synthesis of 2-oxoindolin-3-ylidene 168.

Condensation of 2-indolinones **129** with aryl aldehydes substituted with 1,2,3-triazolyl heterocycle **128** in refluxing ethanol containing a catalytic amount of piperidine gave the corresponding 2-oxoindolin-3-ylidene **130**. The aryl aldehydes bearing 1,2,3-triazolyl heterocycle **128** were obtained through the click reaction of 4-ethynylbenzaldehyde **127** and azidobenzene **126** in DMF containing aqueous $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$, ascorbic acid and a catalytic amount of KI^{110} (Scheme 17). Based on the VEGFR-2 inhibitory properties of the tested **130**, it was observed that the substituent of the phenyl ring attached to the triazolyl nitrogen possesses a significant effect on the observed bio-properties. The potency against VEGFR-2 followed the order of $4\text{-CH}_3 > 3\text{-CH}_3 > 2\text{-CH}_3 > \text{H}$. The antiproliferation properties (CCK-8 assay) were studied against HT-29 (colon), MKN-45 (gastric) and HUVEC (umbilical vein endothelial) cancer cells. Compound **130d** ($\text{R} = \text{H, R}' = 4\text{-MeCH}_2$; $\text{IC}_{50} = 1.61 \pm 0.45, 1.92 \pm 0.37$, and $7.94 \pm 0.36 \mu\text{M}$ against HT-29, MKN-45 and HUVEC, respectively; $\text{IC}_{50} = 26.38 \pm 1.09 \text{ nM}$ against VEGFR-2) was the most promising agent synthesized with anti-proliferation and anti-VEGFR-2 properties comparable to that of sunitinib ($\text{IC}_{50} = 10.34 \pm 0.96, 9.25 \pm 0.77$, and $6.37 \pm 0.59 \mu\text{M}$ against HT-29, MKN-45 and HUVEC, respectively; $\text{IC}_{50} = 83.20 \pm 1.36 \text{ nM}$ against VEGFR-2) (ESI Fig. S8†). Also, its angiogenesis properties were supported by a zebrafish labeling model assay.¹¹⁰

A series of 2-oxoindolin-3-ylidene connected to pyrrole heterocycle **135** and **137** with high structural resemblance to sunitinib was synthesized *via* the condensation of 2-indolinones **129** with 2-pyrrolecarbaldehyde **132**, followed by the reduction of the nitro group (Zn/AcOH). Subsequently, the reaction of **133** with chloroacetyl chloride (TEA, THF) or 3-bromopropionic acid (DMTMM: 4-(4,6-dimethoxytriazine) chlorinated-4-methylmorpholine, DMF) with various amines finally furnished **135** and **137** (Scheme 18). Based on their physicochemical properties and rat aortic ring assay, a few of the synthesized analogs was selected for *in vitro* testing (MTT assay) considering HT-29 (colon) and NCI-H460 (non-small cell lung) cancer cell lines, and compound **138** was selected for more sophisticated cell line and targeted receptor assays (Fig. 11) Compound **138** was nominated as a promising drug candidate based on its observed bio-properties compared to that of sunitinib.³⁹

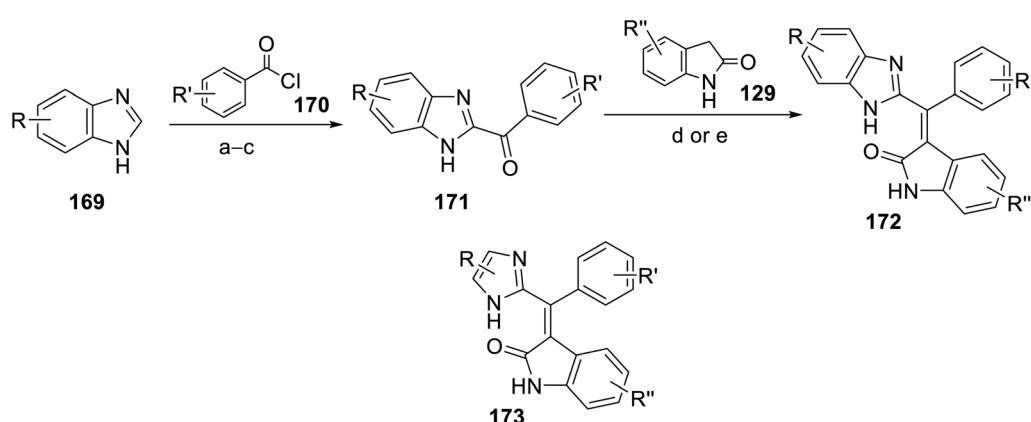

2-Oxoindolin-3-ylidene **141** was obtained through the condensation of 2-indolinone **140** with triethyl orthobenzoate in boiling toluene (110 °C) in the presence of acetic anhydride. The removal of the chloroacetyl group (KOH, MeOH, room temperature), followed by reaction with 4-(1H-pyrrol-1-yl)aniline derivatives **145** gave 2-oxoindolin-3-ylidene **146** (Scheme 19). Some of the synthesized agents **146a** (R=NMe₂) and **146e** (R=1-methyl-4-piperazinyl) exhibited considerable VEGFR-2 and PDGFR- β inhibitory properties compared to that of nintedanib. The most promising agents observed were screened for antiproliferation properties (MTT assay) against HT-29 (colon), SK-OV-3 (ovarian) and HeLa (cervical) cancer cells, exhibiting promising activities (**146a**; IC₅₀ = 51.7, 14.3 nM against VEGFR-2 and PDGFR- β , respectively; IC₅₀ = 0.98 ± 0.11, 5.22 ± 0.36, 53.25 ± 1.20 μ M against HT-29, SK-OV-3 and HeLa cells, respectively and **146e**; IC₅₀ = 38.0, 83.17 nM against VEGFR-2 and PDGFR- β , respectively; IC₅₀ = 3.12 ± 0.27, 25.87 ± 1.32, 30.42 ± 1.98 μ M against HT-29, SK-OV-3 and HeLa cells, respectively) compared to that of nintedanib (IC₅₀ = 3.3, 3.7 nM against VEGFR-2 and PDGFR- β , respectively; IC₅₀ = 4.90 ± 0.65, 28.76 ± 2.13, 51.65 ± 2.68 μ M against HT-29, SK-OV-3 and HeLa cells, respectively)¹¹¹ (ESI Fig. S9†).

Similarly, the reaction of 2-oxoindolin-3-ylidene **147** with various amine-containing heterocycles (benzoxazole **148**, benzimidazole **150** and indole **152**) in refluxing methanol yielded the corresponding 2-oxoindolin-3-ylidenes **149**, **151** and **153**, respectively (Scheme 20). Some of the synthesized agents revealed promising antiproliferation activity (MTT assay) against the A549 (NSCLC), MCF7 (breast) and HT-29 (colon) cancer cell lines with enzymatic inhibitory properties against VEGFR-2 and PDGFR- β (ESI Fig. S10†). It was noticed that the prepared benzoxazolyl

analogs were not tolerated due to either their weak or complete inactivity towards the tested enzymes. Meanwhile, the synthesized compounds with indolyl heterocycle **153** exhibited considerable antiproliferation properties against the MCF7 and/or HT-29 cell lines. Compound **153c** (CR'R''R''' = 2-[4-methylpiperazin-1-yl]carbonyl) was the most effective agent synthesized with promising inhibitory properties against VEGFR-2, -3 and PDGFR- α , PDGFR- β (IC₅₀ = 69.1, 18.2, 4.4 and 22.0 nM, respectively) compared to nintedanib (IC₅₀ = 8.5, 3.2, 2.3 and 3.5 nM, respectively). Furthermore, the safe proliferation behavior of **153c** against the HEK293T (human embryonic kidney) normal cell line supports its use as a promising candidate.¹¹²

2-Oxoindolin-3-ylidenes linked to pyrrolo[3,4-*b*]pyrrol-2-yl **161** were synthesized through the condensation of 2-indolinones **129** with pyrrolo[3,4-*b*]pyrrole-2-carbaldehyde **160** (Scheme 21). The synthesized agents were screened for their antiproliferation properties (MTT assay) against HCT116 (colon), NCT-H460 (NSCLC), and 786-O (renal) cancer in addition to Detroit 551 (fibroblast) normal cell line. Iodoindolinone analog **161e** (R = I) exhibited promising properties against HCT116 and NCT-H460 with potency higher than that of sunitinib (IC₅₀ = 0.42 ± 0.16, 2.95 ± 0.83; 3.42 ± 0.57, 6.23 ± 0.57 μ M for **161e** and sunitinib, respectively). Bromo- **161d** and iodoindolinones **161e** showed considerable inhibitory properties against VEGFR-2 and PDGFR- β compared to that of sunitinib (IC₅₀ = 24.7, 16.1; 35.1, 29.3; and 140.0, 61.4 nM against VEGFR-2 and PDGFR- β for **161d** and **161e** and sunitinib, respectively)¹¹³ (Fig. 12).

A series of 2-oxoindolin-3-ylidenes connected to pyrrolo[*b*] cyclohexyl heterocycle **168** was prepared *via* the condensation

172; R = H, 5-OMe; R' = 2-Me, 3-Me, 4-Me, 3-F, 4-F, 3,5-difluoro, 2,4-difluoro, 4-CF₃, 2,4-dichloro, 4-OMe, 4-OEt, 4-NH₂; R'' = H, 5-Br, 6-Br, 7-Br, 5-CO₂H, 6-CO₂H,

(pyridine containing TiCl_4 “catalyst”) of the ketonic function of $1H$ -indole-3-carboxylate **166** with 2-indolinones **129**, followed by reaction with either primary or secondary amines (in DMF containing EDCI: 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide and HOBT: hydroxybenzotriazole at room temperature) (Scheme 22). Some of the synthesized agents **168** showed promising inhibitory properties against different/multi-targeted tyrosine kinases (VEGFR-2, PDGFR- β and c-kit) compared to that of sunitinib. Furthermore, some of the promising agents were tested for their antiproliferation properties (MTT assay) against BXPC-3 (pancreatic), T24 (bladder), BGC (gastric), HEPG2 (liver) and HT29 (colon) cancer cell lines. Among them, compound **168c** ($\text{R} = 5\text{-Cl}$, $\text{R}' = \text{NH}(\text{CH}_2)_2\text{NEt}_2$) was one of the most promising candidates discovered with antiproliferation ($\text{IC}_{50} = 1.95, 1.83, 2.03, 3.14$, and $6.48 \mu\text{M}$ against BXPC-3, T24, BGC, HEPG2 and HT29, respectively) and enzymatic inhibitory properties ($\text{IC}_{50} = 2.6, 12.1$, and 2.7 nM against VEGFR-2, PDGFR- β and c-kit, respectively) comparable to that of sunitinib ($\text{IC}_{50} = 3.63, 2.44, 4.78, 5.61$ and $1.47 \mu\text{M}$ against BXPC-3, T24, BGC, HEPG2 and HT29; $\text{IC}_{50} = 4.0, 10.6$, and 8.9 nM against VEGFR-2, PDGFR- β and c-kit, respectively)¹¹⁴ (ESI Fig. S11†).

The reaction of benzimidazoles **169** with benzoyl chlorides **170** at 135°C in the presence of TEA led to the formation of *N*- and *C*-

diacylated benzimidazoles. The *N*-acyl function was removed upon refluxing with 7% aqueous HCl. Condensation of the formed benzimidazolyl ketones **171** with 2-indolinones **129** in a sealed tube (90°C) in EtOH/NH_3 gave the targeted 2-oxoindolin-3-ylidene **172**. Similarly imidazolyl connected to 2-oxoindolin-3-ylidene **173** were obtained (Scheme 23).¹¹⁵ Some of the synthesized 2-oxoindolin-3-ylidene **172/173** revealed promising enzymatic inhibitory properties against VEGFR-1 (Flt-1), VEGFR-2 (KDR), FGFR-1 and PDGFR- α compared to sunitinib and SU6668 (standard references). Compounds **172p** ($\text{R} = \text{R}' = \text{H}$, $\text{R}'' = 5\text{-CO}_2\text{H}$), **172t** ($\text{R} = \text{H}$, $\text{R}' = 4\text{-Me}$, $\text{R}'' = 5\text{-CO}_2\text{H}$) and **172v** ($\text{R} = 5\text{-OMe}$, $\text{R}' = \text{H}$, $\text{R}'' = 5\text{-CO}_2\text{H}$) exhibited considerable potencies against VEGFR-2 compared to the standard references used ($\text{IC}_{50} = 4, 5$, and 3 nM , respectively). Additionally, compounds **172af** ($\{\text{R} = 5\text{-OMe}$, $\text{R}' = \text{H}$, $\text{R}'' = 5\text{-NH}[4\text{-}(N\text{-ethylpiperidinyl)}]\}$) and **173c** ($\{\text{R} = \text{H}$, $\text{R}' = 4\text{-Cl}$, $\text{R}'' = 5\text{-NH}[4\text{-}(N\text{-ethylpiperidinyl)}]\}$) ($\text{IC}_{50} = 10, 4 \text{ nM}$, respectively) showed promising enzymatic inhibitory, ADME properties and cellular potencies¹¹⁵ (ESI Fig. S12†).

5. Indole heterocycle conjugates

Bio-conjugation is one of the most powerful and attractive rational drug design strategies used for the development of new drug candidates by connecting two or more therapeutic

Scheme 25 Synthesis of indole triazole conjugates 182–186.

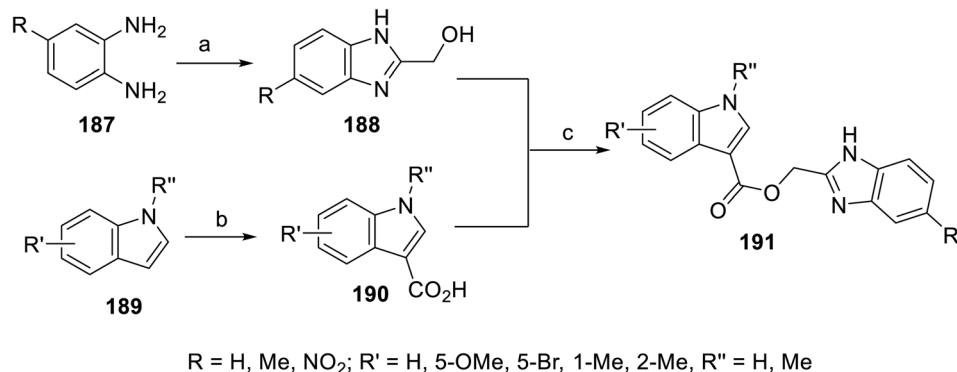

pharmacophoric functions/fragments/agents.^{116,117} Many conjugates have been reported to possess diverse potential bio-properties, among which vasodilation is useful for smooth muscle relaxation,^{118,119} anti-inflammatory, analgesic,^{120–123} antibacterial,^{124–126} antimycobacterial,¹²⁷ antimalarial,¹²⁸ anti-viral including anti-SARS-CoV-2,^{129–133} HCV “hepatitis C viruses” and chikungunya,¹³⁴ anti-parasitic¹³⁵ and antitumor.^{136,137}

5.1. Indole triazole conjugates

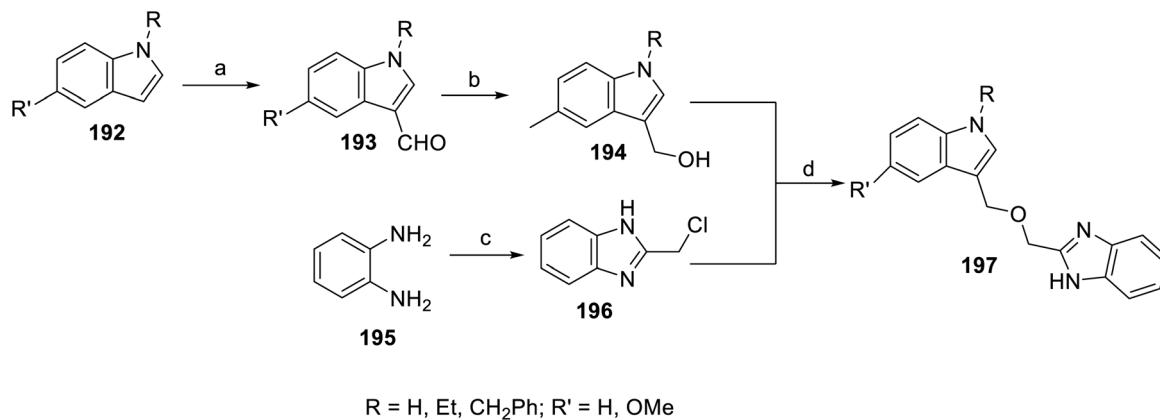

The condensation reaction (in refluxing acetic acid) of the appropriate aromatic aldehyde with indole triazole conjugate

bearing an amino function 176 (obtained through reaction of 2-indolecarbohydrazide 174 with CS_2/KOH followed by hydrazonolysis ($\text{NH}_2\text{NH}_2 \cdot \text{H}_2\text{O}$ in refluxing EtOH)) afforded the corresponding Schiff base 177. The reaction of 177 with hydrazoneoyl chlorides 178 or phenacyl bromides 180 (in dioxane, Et_3N) afforded the corresponding conjugates 179 and 181¹³⁸ (Scheme 24). Some of the synthesized agents were observed to exhibit considerable VEGFR-2 inhibitory and antiproliferation properties (MTT assay, against human renal cancer cell lines CAK-1 and A498). The most promising agents discovered were 179c ($\text{Ar} = 4-\text{H}_3\text{CC}_6\text{H}_4$; $\text{IC}_{50} = 0.075 \pm 0.002 \mu\text{M}$ against VEGFR-2;

Scheme 26 Synthesis of indole benzimidazole conjugates 191.

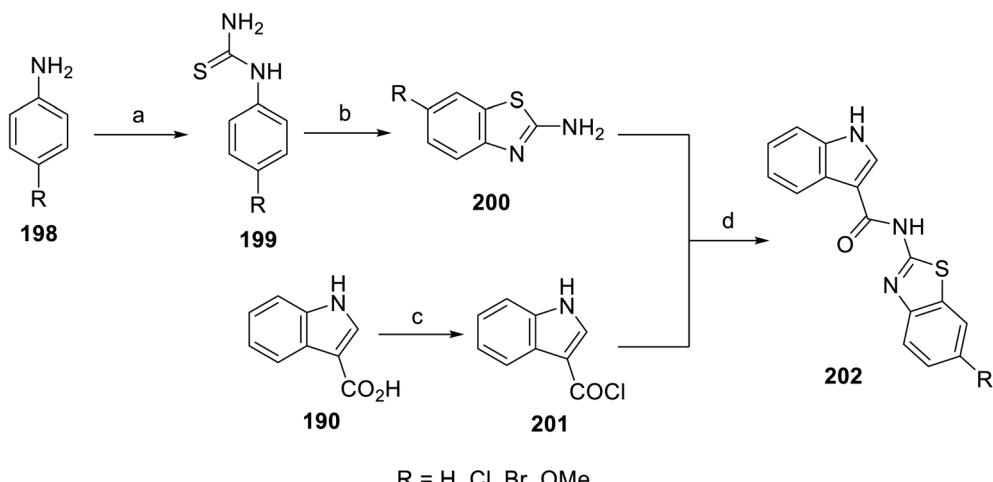

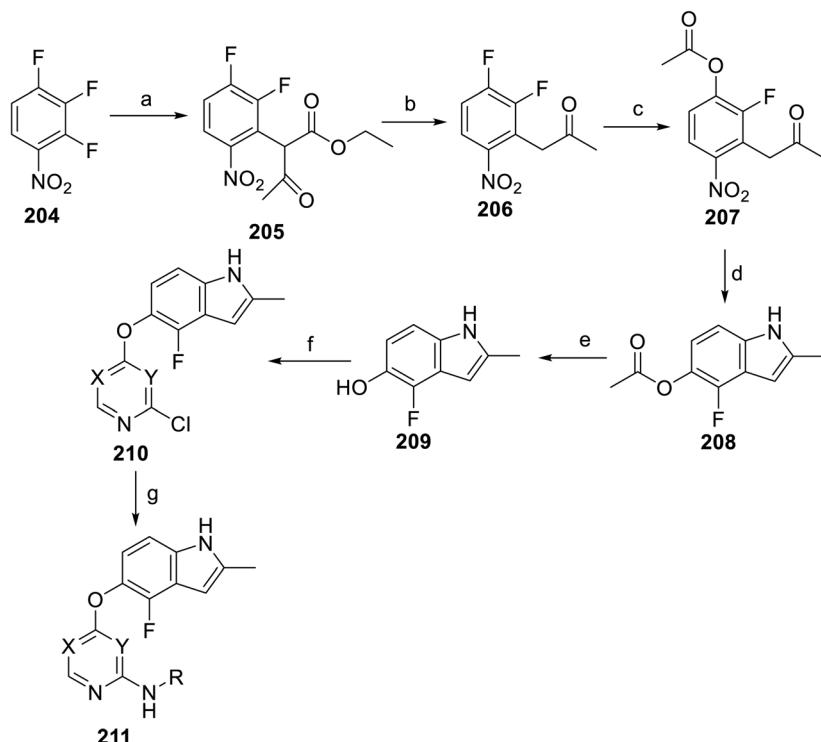

Scheme 27 Synthesis of indole benzimidazole conjugates 197.

$IC_{50} = 3.23 \pm 0.15$ and $2.05 \pm 0.09 \mu\text{M}$ against CAKI-1 and A498 cell lines, respectively) and **181g** ($\text{Ar} = 4\text{-MeOC}_6\text{H}_4$, $\text{R} = \text{Cl}$; $IC_{50} = 0.071 \pm 0.002 \mu\text{M}$ against VEGFR-2; $IC_{50} = 0.89 \pm 0.04$ and $2.2 \pm 0.1 \mu\text{M}$ against CAKI-1 and A498 cell lines, respectively) compared to sunitinib ($IC_{50} = 0.075 \pm 0.002 \mu\text{M}$ against VEGFR-2; $IC_{50} = 4.93 \pm 0.16$, $1.25 \pm 0.04 \mu\text{M}$ against CAKI-1 and A498 cell lines, respectively) with a safety profile upon testing against the RPTEC/TERT1 non-cancer cell line¹³⁸ (ESI Fig. S13†).

Glycosylation of Schiff base **177** with either acetobromoglucose or acetobromogalactose (K_2CO_3 , acetone at room temperature) gave a mixture of *N*-glycosylated **182** and *S*-analog **183**. However, the reaction of **177** with acrylonitrile (Michael acceptor) in refluxing ethanol containing Et_3N afforded the corresponding *N*-substituted Michael adduct **184**. Meanwhile, the reaction of **177** with allyl bromide (equimolar values) in acetone/DMF (1 : 1 v/v) containing Et_3N at room temperature as a basic catalyst gave the *S*-allylated analog **185**. Meanwhile, utilizing K_2CO_3 in the

same reaction (using 3.3 molar value equivalent of allyl bromide relative to **177**), the allylation of both the indolyl nitrogen and *S*-function of triazolyl heterocycle **186** was achieved. The same product was obtained upon reacting *S*-allylated analog **185** under the same conditions (2.2 molar equivalent value) (Scheme 25). The antiproliferation properties of the synthesized conjugates **182–186** were studied against the MCF7 (breast) and HepG2 (liver) cancer cell lines (MTT assay) utilizing 5-fluorouracil and sorafenib as reference standards. Also, the VEGFR-2 inhibitory properties were studied for the most effective antiproliferative agent observed, supporting that compound **185** is a promising conjugate ($IC_{50} = 1.18 \pm 0.15$ and $7.09 \pm 0.67 \mu\text{M}$ against MCF7 and HepG2 cell lines; $IC_{50} = 19.8 \pm 1.58 \text{ nM}$ against VEGFR-2, respectively) compared to sorafenib ($IC_{50} = 2.13 \pm 0.24$ and $3.24 \pm 0.23 \mu\text{M}$ against MCF7 and HepG2 cell lines; $IC_{50} = 30.0 \text{ nM}$ against VEGFR-2, respectively). The safe profile of compound **185** was supported through antiproliferation studies against the MDA-MB-

Scheme 29 Synthesis of indole-pyrimidine conjugates 211.

with 2-aminobenzothiazoles 200 (in CH₂Cl₂ containing Et₃N at room temperature) (Scheme 28). The synthesized conjugates exhibited considerable inhibitory properties (Fig. 13) compared to that of sunitinib (% inhibition of VEGFR-2 at 10 μM = 98.1).¹⁴⁰

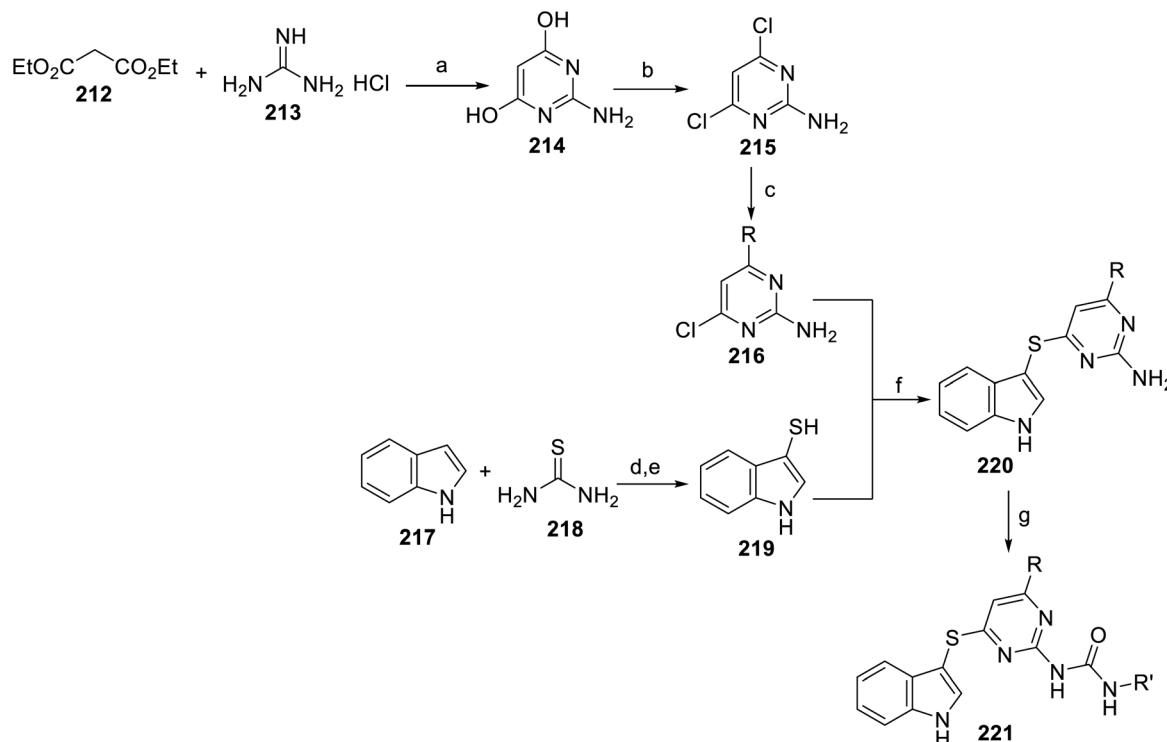

5.4. Indole-pyrimidine conjugates

Pazopanib 203 (Fig. 14) is an FDA approved VEGFR-2 inhibitor for the treatment of advanced renal cell cancer (2009) and soft tissue sarcoma.^{141,142} In this molecule, the pyrimidinyl pharmacophoric heterocycle is attached to an indazole heterocycle. This inspired the design, construction and VEGFR-2 inhibitory properties investigation of indole pyrimidine conjugates linked through an ether linkage.¹⁴³ A set of indole pyrimidine conjugates 211 was synthesized through the coupling of 5-hydroxyindole derivative 209 with 2,4-dichloropyrimidine or 4,6-dichloropyrimidine in Me₂CO containing aq. NaOH, followed by reaction with various primary amines (HCl “36%”, *i*-PrOH, sealed tube, 100 °C) (Scheme 29). Some of the synthesized

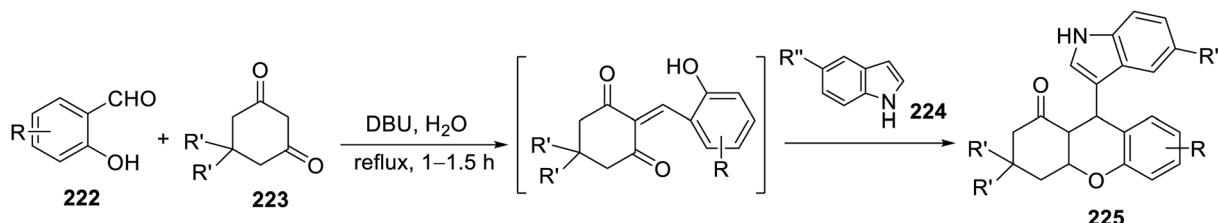

conjugates 211 were observed to exhibit considerable VEGFR-2 inhibitory properties. Among them, the most promising was 211k [R = 3-(MeSO₂C₆H₄)CH₂] compared to sunitinib (IC₅₀ = 0.0038 ± 0.0033, 0.0022 ± 0.0005 μM, respectively) (ESI Fig. S16†). Additionally, compound 211k exhibited inhibitory properties against VEGFR-1, VEGFR-3, PDGFR-α and PDGFR-β (IC₅₀ = 40.4, 515.8, 24.1 and 33.6 nM, respectively) and can be nominated as multi-targeted tyrosine kinase inhibitor.¹⁴³

Indole pyrimidine conjugates 221 connected through a thioether linkage were also reported. The reaction of indole-3-thiol 219 with 6-chloro-2,4-diaminopyrimidines 216 (obtained from condensation of diethylmalonate 212 and guanidine hydrochloride 213 under basic condition, followed by chlorination with POCl₃, and then reaction with either primary or secondary amine) in refluxing ethanol containing Et₃N and KI gave 220, which was reacted with isocyanate in refluxing 1,4-dioxane, finally giving 221¹⁴⁴ (Scheme 30). Some of the synthesized agents exhibited promising antiproliferation properties (MTT

Scheme 30 Synthesis of indole-pyrimidine conjugates 221.

Scheme 31 Synthesis of indole chromene conjugates 225.

assay) against A549 (lung), PC-3 (prostate), MDAMB-231 (breast) and HepG2 (liver) human cancer cell lines with promising VEGFR-2 properties compared to that of sorafenib. The most promising was 221k (R = 1-pyrrolidinyl, R' = 4-ClC₆H₄; IC₅₀ = 6.41 ± 0.81, 10.42 ± 0.78, 5.85 ± 0.71, and 7.87 ± 1.18 μM against A549, PC-3, MDAMB-231 and HepG2, respectively with % inhibition = 0.33% ± 0.04% of VEGFR-2 at 10 μM) compared to that of Sorafenib (IC₅₀ = 7.43 ± 0.81, 9.77 ± 1.12, 11.84 ± 1.25, 5.78 ± 0.41 μM against A549, PC-3, MDAMB-231 and

HepG2, respectively with % inhibition = 1.21% ± 0.02% of VEGFR-2 at 10 μM)¹⁴⁴ (ESI Fig. S17†).

5.5. Indole chromene conjugates

A multi-component eco-friendly synthetic procedure was employed for the preparation of indole chromene conjugates 225 via the one-pot reaction of salicaldehydes 222, with the appropriate 1,3-cyclohexanones 223 and indole derivative 224 in refluxing water containing DBU (1,8-diazabicyclo[5.4.0]undec-7-

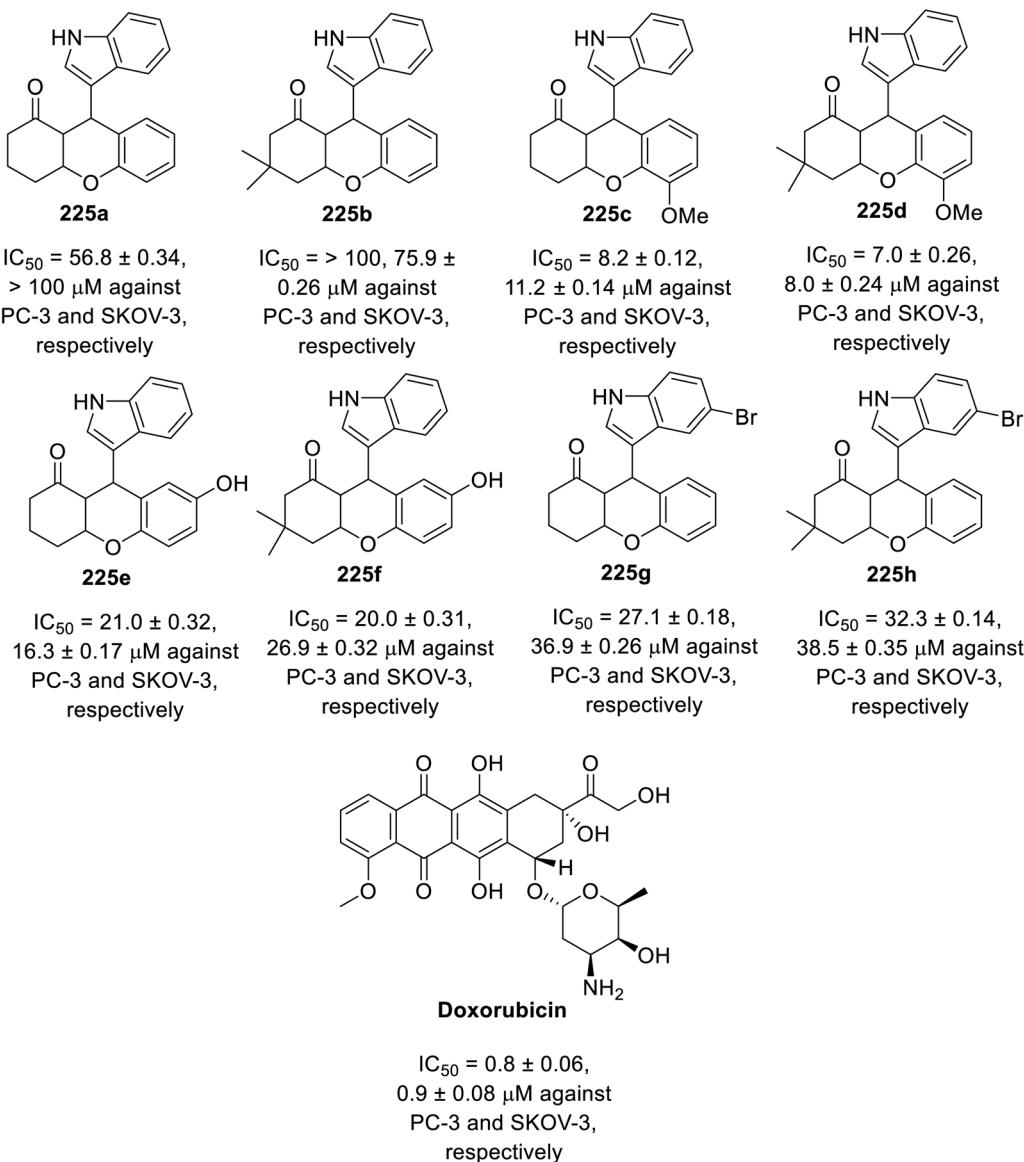

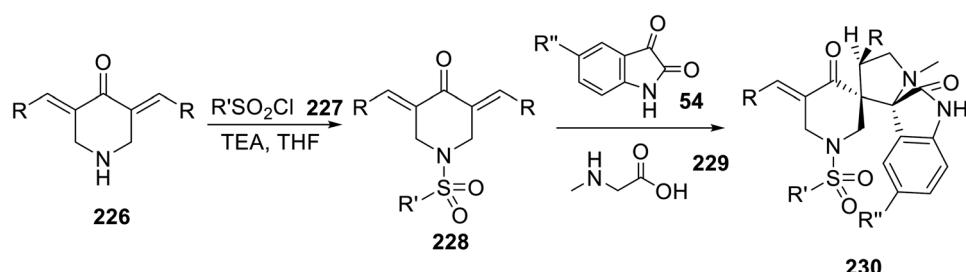

Fig. 15 Antiproliferation properties of indole chromene conjugates 225 and doxorubicin (standard reference).

ene). The reaction was assumed to take place *via* the base-catalyzed Michael addition of indole to the Knoevenagel adduct formed from the condensation of the salicaldehyde with 1,3-cyclohexanone assisted by the basic catalysis of DBU⁴⁵ (Scheme

31). The synthesized conjugates 225 exhibited mild antitumor properties (MTT assay) against the PC-3 (prostate) and SKOV-3 (ovarian) cancer cell lines compared to that of doxorubicin (Fig. 15). Their VEGFR-2 inhibitory properties were reported based

R = Ph, 4-FC₆H₄, 4-CIC₆H₄, 4-BrC₆H₄, 3,4-(MeO)₂C₆H₃; R' = Me, Et; R'' = H, Cl

Scheme 32 Synthesis of spiroindoles 230.

on the molecular modeling technique (PDB ID: 4ASD, AutoDock Tools 4.2).¹⁴⁵ However, theoretical (molecular modeling) studies are insufficient supporting evidence for assigning the mode of action, and thus experimental data is required.

6. Spiroindoles

Spiroindoles occupy a unique place in heterocyclic chemistry due to the versatile bio-properties of their natural and synthetic analogs¹⁴⁶ (exemplified by antibacterial, antifungal,^{147–151} antimycobacterial,^{152–154} antiviral,^{19,155} anticancer,^{156–160} antimalarial,^{161,162} anti-inflammatory¹⁶³ and antihyperglycemic^{164,165}). [3 + 2]-Dipolar cycloaddition of azomethine ylides derived from isatin derivatives with α -amino acids to the exocyclic olefinic linkage derived from alicycles or heterocycles is an accessible synthetic approach successfully used for the construction of various spiroindoles with regio- and stereoselectivity.^{146,166–168} Many antitumor active agents against various human tumor cell lines were optimized *via* the above-mentioned synthetic approach; however, the VEGFR mode of action was only assigned for a few analogs.^{169,170}

Spiroindoles **230** were regioselectively synthesized through the one-pot three-component reaction of 3,5-diylidene-4-piperidones **228** and azomethine, which were formed by the condensation of isatins **54** and sarcosine **229** in refluxing ethanol (Scheme 32). The stereochemical structure of **230** was established by single crystal X-ray studies. Promising anti-proliferation properties were exhibited by some of the synthesized spiroindoles **230** against the MCF7 (breast), HCT116 (colon), A431 (skin squamous) and PaCa2 (pancreatic) cancer cell lines (MTT assay) compared to the standard references (sunitinib and 5-fluorouracil). Safe behaviors against the non-cancer RPE1 cell line were revealed by the synthesized agents. Considerable multi-targeted inhibitory properties (western blotting technique) were exhibited by the synthesized agents against VEGFR-2 and EGFR. The SAR (structure–activity relationship) study indicated that the chloro-substituted indolyl heterocycle can optimize efficient agents against the tested cancer cell lines. Compound **231n** ($R = 4\text{-BrC}_6\text{H}_4$, $R' = \text{Me}$, $R'' = \text{H}$) was the most promising agent observed ($\text{IC}_{50} = 3.597 \pm 0.19$, 3.236 ± 0.27 , 2.434 ± 0.18 , 12.500 ± 0.67 , and $14.894 \pm 1.61 \mu\text{M}$ against the MCF7, HCT116, A431, PaCa-2 and RPE1 cell lines, respectively; % inhibition = 61.3% and 65.6% against VEGFR-2 and EGFR at the IC_{50} value observed against MCF7, respectively) compared to sunitinib ($\text{IC}_{50} = 3.97 \pm 0.32$, 9.67 ± 0.22 , and $16.91 \pm 0.95 \mu\text{M}$ against MCF7, HCT116, and PaCa-2 cell lines, respectively; % inhibition = 74.7% and 81.4% against VEGFR-2 and EGFR at IC_{50} value observed against MCF7, respectively)¹⁹ (ESI Fig. S18†).

7. Conclusion

Tyrosine kinases are capable of many diverse cellular functions including growth, proliferation, differentiation and death. VEGFR is one of the targeted therapeutic approaches that is preferable to the classical non-selective therapies to minimize the associated side effects or drawbacks. VEGF is an important

category of tyrosine kinases, which can stimulate angiogenesis. VEGFR-2 is the most well-known factor in the angiogenesis of different solid tumors (colon, breast, ovary, lung, skin, renal, head, neck, lymphoma, *etc.*). Indolyl therapeutics have been approved against some serious types of cancer. Additionally, research efforts identified natural and synthesized antitumor indole-containing compounds with promising anti-VEGFR properties. Computational/theoretical studies can assist in designing and identifying novel hits/leads of anti-VEGFR agents; however, without experimental supporting their enzymatic properties, the predictions cannot be considered for further investigations or utilization.
