Synthesis, characterization, and biomedical evaluation of ethylene-bridged tetra-NHC Pd(II), Pt(II) and Au(III) complexes, with apoptosis-inducing properties in cisplatin-resistant neuroblastoma cells†

Wolfgang R. E. Büchele, (1) ‡ Tim P. Schlachta, (1) ‡ Andreas L. Gebendorfer, Jenny Pamperin, Leon F. Richter, (1) Michael J. Sauer, Aram Prokop*bcd and Fritz E. Kühn (1) **a

Synthesis and characterization of the first two cyclic ethylene-bridged tetradentate NHC ligands, with an unsaturated (imidazole) and saturated backbone (2-imidazoline), are described. Complexes of both ligands containing palladium(II) have been obtained. For platinum(II) and gold(III), only the unsaturated tetracarbene complexes could be isolated. The attempts to synthesize a methylene-bridged 2-imidazoline macrocycle are also described. Furthermore, a novel bisimidazolinium ligand precursor and its open-chain Pd^{III} and Pt^{III} tetracarbene complexes are obtained. Finally, it is shown that the unsaturated gold(III) tetracarbene is able to induce apoptosis in malignant SK-N-AS neuroblastoma cells *via* the mitochondrial and ROS pathway and overcomes resistance to cisplatin *in vitro*.

Introduction

N-heterocyclic carbenes (NHCs), first described in 1991,¹ have found many applications.² There are several structural features that allow the tuning of their electronic properties. Ring size, the adjacent heteroatoms, *N*-substituents, and the backbone can be modified. Changing one or more structural properties of a NHC ligand can lead to significantly different reactivities and stabilities of the resulting complexes.³ Often several NHC units are combined in multidentate ligands, making use of the chelating effect, and a plethora of multidentate NHC metal complexes has been reported.⁴,⁵

Our group has developed several bidentate and cyclic tetradentate NHC ligands. The respective transition metal complexes have been applied *e.g.* in medicinal chemistry^{6,7} and epoxidation catalysis.³ While the bidentate ligands can form open-chain tetracarbene complexes,^{8,9} the tetradentate ligands give cyclic tetracarbene compounds. Most commonly applied in our recent examinations is the calix[4]imidazolium ligand precursor (a, Fig. 1).¹⁰ Its iron complex (c) can be used as olefin epoxidation catalyst achieving unprecedented activity.³ Coinage metal tetracarbene complexes (and metal NHC complexes in general^{11–17}) have been investigated regarding their antiproliferative activity and selectivity against cancer cells (b, d-f, Fig. 1).^{6,7}

Paper

In this study, the scope of multidentate NHC ligands is extended with an ethylene-bridged bisimidazolinium ligand precursor and two cyclic ethylene-bridged tetradentate NHC ligands, with an unsaturated (imidazole) and saturated backbone (2-imidazoline). Pd^{II} , Pt^{II} and Au^{III} tetracarbene complexes containing the novel ligands are synthesized, characterized and applied in preliminary medicinal studies regarding their activity in inducing apoptosis in malignant cells. Finally, the synthetic attempts to a calix[4]imidazolinium macrocycle (structurally analog to $\bf c$ but with a saturated backbone) are described, because there is an increasing demand for reliable training data, including data on negative outcomes, for machine

Especially the two new macrocyclic ligand precursors are intended to lay the foundation for electronic comparisons induced by the different backbone in future studies. The unsaturated backbone of the imidazole moiety causes partial aromaticity, increasing NHC stability by ca. 100 kJ mol $^{-1}$. A saturated backbone, in turn, can lead to higher basicity because the electron density is more concentrated on the C2 carbene carbon atom due to the lack of π -interactions. 22

Results and discussion

learning systems in chemistry.18

The synthesis of a saturated macrocyclic ligand precursor similar to **c**, but containing 2-imidazoline moieties instead of imidazole, calix[4]imidazolinium, was pursued parallel to the synthesis of the other ligand precursors. However, the synthesis was not successful with the chosen synthetic approaches as described in the ESI.†

Synthesis and characterization of H₂L3

 H_2L3 is based on the literature known ethylene-bridged imidazoline moiety (1).²³ Alkylation of 1 with MeI in MeCN at 82 °C, followed by an anion exchange with NH_4PF_6 in water, gives H_2L3 in 91% yield (Fig. 2).

Synthesis and characterization of H₄L5/6 and H₄L8/L9

For the preparation of $H_4L5/6$ and $H_4L8/9$, a slightly modified literature procedure for similar macrocycles was used (Fig. 3). Ring closure to form the macrocyclic imidazolium salt $\bf a$ is commonly achieved with $CH_2(OTf)_2$, but also CH_2Br_2 is reported. Here the ethylene-bridged imidazoline $\bf 1$ (ref. 23) and the ethylene-bridged imidazole $\bf 7$ (ref. 25) are reacted with ethylene bistriflate (4) under dry conditions at $\bf -45$ °C over a period of 5 h in dry MeCN for $\bf H_4L5$ and $\bf H_4L8$ (see ESI†).

Fig. 2 Synthesis of ligand precursor $H_2L3\ \emph{via}$ alkylation and anion exchange.

Fig. 3 Synthesis of ligand precursors $H_4L5/6$ and $H_4L8/9$ via ring closure with ethylene bistriflate and anion exchange.

The synthesis of **H₄L5** and **H₄L8** yields a mixture of a 20-membered macrocycle (87% **H₄L5** and 90% **H₄L8**, as determined by NMR), consisting of four imidazole (C[4]) units, and a 30-membered macrocycle (13% **H₄L5**, 10% **H₄L8**) consisting of six imidazole (C[6]) units (see ESI†). Separation attempts of C[4] and C[6] *via* column chromatography, precipitation or sublimation were not successful. However, by increasing the cooling period during the addition of the ethylene bistriflate at -45 °C to a total of 5 h, the purity of the kinetically preferred C[4] unit could be easily increased up to 98% C[4] for **H₄L5** and in case of **H₄L8** an increase up to 100% (ESI†). Due to the absence of similar macrocyclic imidazolinium compounds, **H₄L5** is compared to **a** and **H₄L8** in the following.³

Relative to a, all signals of H₄L5 and H₄L8 are upfield shifted, indicating a higher electronic density due to the +I effect of the ethylene bridge leading to an increased shielding effect in the NMR.^{10,26} The higher upfield shift of H₄L5 compared to H₄L8 can be explained by the electronic inducing effect of the saturated bond.^{20,26,27}

Unlike in ¹H-NMR, each individual ¹³C signal of **H₄L8** in DMSO-d₆ is in the same range as the signals obtained for the macrocyclic compound **a**. ¹⁰ However, in case of **H₄L5**, opposite to the ¹H-NMR, the C2 carbon resonance at 159.16 ppm is downfield shifted compared to **H₄L8** and **a** (**H₄L8**, $\Delta \delta \leq 22.08$ ppm, **a**, $\Delta \delta \leq 22.0$ ppm), thus contradicting expectations. According to literature and as described by H. V. Huynh, the hypothetical free carbene of the imidazoline ligand **H₄L5** should be a stronger σ -donor than **H₄L8**, so an enhanced upfield shift of the C2 signal of **H₄L5** should have been detectable. ^{20,28,29} Interestingly this expectation is not met here, and apparently other factors play a role. Every other resonance in the ¹³C-NMR is upfield shifted. ¹⁰

Salt metathesis of the formed macrocyclic salts can be performed with NH_4PF_6 to increase the solubility in organic solvents and as additional purification step.^{3,30} Thus, an anion exchange in water towards PF_6^- is conducted with H_4L5 and H_4L8 , resulting in H_4L6 (81%) and H_4L9 (88%).

Synthesis and characterization of complexes (Pd/PtL3, PdL5/6, Pd/PtL8, Pd/AuL9)

A well-established route to obtain NHC complexes is to convert the corresponding imidazolium salts with group 10 metal acetates. In this reaction, the acetate serves as an internal base capable of deprotonating imidazolium and imidazolinium **RSC Advances**

salts to form NHCs, which subsequently coordinate to the metal. 6,31-33 An alternative route is *via* a silver transmetalation. 34 In the first approaches, attempts were made to synthesize the respective Ag^I complex with H₂L3 to obtain a dinuclear structure similar to already published open chain bis-NHCcomplexes. 9,25,35 However, no product formation was observed in our case. Either no reaction took place or complex signals were observed in the aliphatic region of $\delta = 1.9$ –4.4 ppm in the ¹H-NMR after purification, indicating the decomposition of H₂L3. Several other conditions with different Ag^I-salts and addition of sodium acetate as internal base at different temperatures were tested without success. A possible problem might be the stability of the AgI-complex. Another issue might be hydrolysis of imidazolines under acidic and basic conditions. 36,37 It has been proposed in literature that the moisture in the solvent can react with sodium acetate to generate hydroxide ions which can attack the electrophilic center of the C2 carbon and lead to ring-opening products, rather than nucleophilic attacking the acidic proton at the C2 carbon.38 Therefore, the next attempts were conducted under moisture-free reaction conditions by using dried solvents. Even the direct metalation with palladium(II) acetate or palladium(II) chloride under dry reaction conditions did not lead to the desired product. The focus was then shifted to a combination of the transmetalation route using Ag₂O in situ with the direct metalation, by applying the respective metal precursor and sodium acetate as a mild base in dry solvents (Fig. 4).

The absence of the acidic imidazolinium proton signal and appearance of characteristic carbene carbon signals confirms the successful formation of PdL3 and PtL3. Unfortunately, despite several attempts, a clean elemental analysis for PtL3 could not be obtained. Also, the ¹H-NMR of PtL3 shows some impurities, which could not be identified and no 195Pt isotope coupling phenomena was observed in the ¹³C-NMR.

The carbon signal of PdL3 at 194.29 ppm in DMSOd₆ [PtL3; 188.38 ppm in CD₃CN], is surprisingly downfield shifted compared to other Pd(II) bis-NHCs reported in literature. 39,40 Due to the theoretically stronger σ -donation of the imidazolinylidene ligand H2L3 compared to its unsaturated analog, an upfield shift of the 13CNHC signal was expected. Literature indicates that the significant downfield shift of the carbene carbon resonance from imidazolium to imidazolinium compounds is a general phenomenon. ^{38,41,42} Another interesting fact is that the analytic data, including HR-ESI-MS and elemental analysis, are not supporting a dinuclear complex or a mono-carbene complex as expected, but indicate that PdL3 has rather a $[Pd(L3)_2](PF_6)_2$ structure similar to e. This is further

Fig. 4 General synthesis of Pd/PtL3.

Fig. 5 ORTEP-style representation of the cationic fragment of complex PdL3. Hydrogen atoms and hexafluorophosphate anions are omitted for clarity. Thermal ellipsoids are shown at a 50% probability level. Selected bond lengths (Å) and angles (°): C1-Pd1 2.039(2); C7-Pd1 2.038(2); C7_a-Pd1-C7 180.0; C7-Pd1-C1_a 91.64(9); C7-Pd1-C1 88.36(9), C7_a-Pd1-C1_a-N2_a 55.30.

confirmed by single-crystal X-ray diffraction (SC-XRD). The PdL3 complex displays a distorted square planar structure. Two L3 ligands coordinate to the Pd center, resulting in an openchain tetracarbene complex of similar geometry like the cyclic complex e.34 The Pd-C (2.039 Å, 2.038 Å) distances are in good accord with palladium(II) NHC complexes reported in literature. 34,39 The alkyl groups of the ligand L3 adopt a syn conformation in the solid state, while the imidazole rings are tilted by 55.30° out of the palladium square plane (Fig. 5).

The PtL3 complex exhibits a similarly distorted square planar structure compared to PdL3. The Pt-C (2.033 Å, 2.039 Å) distances are comparable to similar literature known group 10 NHC compounds. 43-47 The alkyl groups of L3 also adopt a syn conformation, while the imidazole rings are tilted by 50.53° out of the palladium square plane as in PdL3 (Fig. 6).

Complex PdL5/6 and PdL8/9

Since H_4L5 and H_4L8 are quite similar to other macrocycles (a), it seemed suitable to synthesize PdL5 and PdL8 according to alike compounds via the direct metalation route.32 Therefore, H₄L8 was first converted with Pd(OAc)₂ in a mixture of dry

Fig. 7 General synthesis of PdL5/6, Pd/PtL8 and Pd/AuL9.

DMSO/MeCN (1:1) at 40 °C for 16 h.³⁴ However, no product formation was observed after work-up. Several other conditions such as increasing temperature and reaction time led to the absence of the imidazolium protons and the formation of new product signals in the ¹H-NMR after 4 d at 80 °C. Still these intensities were very low, and no product could be isolated. Another approach was tried *via* the transmetalation route with Ag¹ salts, but this also led to no product formation. Finally, both PdL8 (50%, Fig. 7) and PdL5 (3%) could be obtained by applying the same reaction conditions as for the already synthesized complexes PdL3 and PtL3. The yield of the imidazolinylidene tetracarbene complex could be increased to 46%, by using H₄L6 instead of H₄L5, resulting in PdL6.

Again, the absence of the acidic position 2 proton signals in the ¹H-NMR and appearance of the carbene carbon peaks confirm the formation of Pd(II) carbene complexes. The observed chemical shift of **PdL8** is in the typical range of Pd(II) tetra-NHC compounds and indicates the formation of a complex with similar coordination sphere as e. 6,34,45 The ¹H-NMR of PdL5 in CD₃CN shows three signals, with two of them in a similar range to PdL8 and one upfield shifted signal of the backbone protons. As already mentioned in the discussion of H₄L5, the ¹³C-NMR of PdL5 is contrary to expectations. The carbene carbon of PdL5 (191.30 ppm) is surprisingly strong downfield shifted compared to PdL8 (165.84 ppm) and in a similar range to the carbene carbon of PdL3 (195.6 ppm in CD₃CN). Literature indicates that the significant downfield shift of the carbene carbon resonance from imidazole to imidazoline compounds is a general phenomenon. 38,41,42 The uncertainty of a ¹³C-NMR measurement is expected to be below 0.1 ppm; by using three times the weighted standard deviation, a difference of >0.4 ppm is required for a significant difference that exceeds the statistic uncertainty.3,48 Therefore, PdL5 (191.30 ppm in CD₃CN) and PdL8 (165.84 ppm in CD₃CN) show a sufficiently different chemical shift to allow its discussion. In general, the normal NHC unit (without any modification) of the tetracarbene ligands is in a range of rather low to negligible π backdonation, hence the changes in electronic properties are dominated by the σ -donation of the tetracarbenes.^{3,29} According to literature, the imidazoline ligand L5 should be in general

Fig. 8 ORTEP-style representation of the cationic fragment of complex PdL9. Hydrogen atoms and hexafluorophosphate anions are omitted for clarity. Thermal ellipsoids are shown at a 50% probability level. Selected bond lengths (Å) and angles (°): C1–Pd 2.019(2), C1–Pd1–C1_b 172.03(12), C1–Pd1–C1_d–N2_d 53.62, C5–Pd1–C5_b 98.97°.

a stronger σ -donor than L8, so an enhanced upfield shift of the carbene signal would have been detectable.3,20,28,29 Interestingly, this expectation is also not met here, and apparently other factors may play a role, as already observed with PdL3 and PtL3. Therefore, further investigations on this subject, e.g. by means of DFT calculations, have to be carried out, since only conjectures can be made with the present analytical data. The elemental analysis and HR-ESI-MS for PdL8 are in accord with a composition [Pd(L8)](OTf)2 similar to e. It needs to be noted that no clean elemental analysis of PdL6 could be obtained. However, the elemental analysis and HR-ESI-MS of PdL6 are in accordance with the composition [PdL6](PF₆)₂. Due to unsatisfying results in crystallization of PdL8, an anion exchange in water towards PF₆ was conducted, resulting in PdL9 (41%). Single crystals suitable for SC-XRD were obtained by slow diffusion of Et₂O into MeCN solution of PdL9. As expected, the Pd(II) ion is coordinated in a nearly square planar fashion with C-Pd-C angles deviating from 180° by ~8°, thus lifting the metal slightly above the carbene carbon atom plane (Fig. 8). However, due to the C₂-bridge, the ligand is strongly bent (C5- $Pd1-C5_b = 98.97^\circ$) and adopts a crisp-shape, while tilting the imidazole rings 53.62° in an alternating pattern out of the palladium square plane.49 The Pd-C distance (2.019 Å) is comparable to those of other cyclic Pd(II) tetracarbene compounds reported in literature. 6,34,43,45-47

In the following Table 1 the M- $C_{carbene}$ bond lengths [Å], the $C_{carbene}$ -M- $C_{carbene}$ angle [°], the tilt of the NCN unit [°] of the complexes **Pd/PtL3** and **PdL9** and additionally the C_{bridge} -M- C_{bridge} angle [°] for **PdL9** are summarized.

Table 1 Summary of the M-C_{carbene} bond lengths [Å], the C_{carbene}-M-C_{carbene} angle [°], the tilt of the NCN unit [°] of the complexes Pd/PtL3 and PdL9 and the C_{bridge}-M-C_{bridge} angle [°] for PdL9

RSC Advances Paper

Complex PtL8

Applying the same reaction conditions and work-up methods to Pt(MeCN)₂Cl₂ instead of Pd(OAc)₂ results in the formation of PtL8 (25%, Fig. 7). The absence of acidic proton signals in the ¹H-NMR and the appearance of the carbene ¹³C-peak at 159.39 ppm in CD₃CN confirms the formation of the respective Pt(II) complex. The chemical shift of the carbene carbon is in accordance with Pt(II) tetra-NHC complexes previously reported in literature and is slightly shifted to the upfield compared to PdL8 (13C_{NHC} in CD₃CN at 165.84 ppm) by 6.45 ppm. 43,46,50 No ¹⁹⁵Pt isotope coupling was observed. The ¹H-NMR in CD₃CN shows similar signals compared to PdL8, where the bridge protons also split into two multiplets at 5.01 and 4.44 ppm. In addition, HR-ESI-MS is in accordance to a similar composition as PdL8. Despite multiple attempts, no single crystals suitable for SC-XRD were obtained. However, the discussed analytical data strongly support a similar structure compared to PdL8 and similarly structured tetracarbene ligand.^{6,34}

Complex AuL9

For the synthesis of AuL9 (Fig. 7), the same reaction conditions were applied as reported in the literature for similar complexes.51 Therefore, H4L8 was converted with KAuCl4 and NaOAc in dry DMSO under exclusion of light at 100 °C for 5 h. After the work-up, including an ion exchange to PF₆⁻ as a purification step, AuL9 (47%) was obtained. The absence of acidic proton signals in the ¹H-NMR and the appearance of a new ¹³Cpeak at 146.03 ppm in CD₃CN confirm the formation of the respective Au(III) complex. The chemical shift of the carbene carbon is in accord with Au(III) tetracarbene complex (e) previously reported in literature and slightly downfield shifted by 1.79 ppm when compared to e.51 Furthermore, the backbone carbons are also slightly downfield shifted by 0.68 ppm. The ¹H-NMR in CD₃CN shows similar signals compared to complex PdL8 and PtL8 with the backbone protons at 7.47 ppm and the bridge protons as two multiplets in close proximity at 4.83 and 4.71 ppm. Both elemental analysis⁵² and HR-ESI-MS are in agreement with the composition [Au(L15)](PF₆)₃. Although no single crystals suitable for SC-XRD were obtained, the discussed analytical data strongly support the coordination of one tetracarbene ligand similar to PdL9.

Biological evaluation

Induction of apoptosis as cell death type

PdL3, PdL8, AuL9 and their respective protonated ligand precursors were tested for their apoptotic effects on Nalm-6 cells (human B cell precursor leukemia cell line) and SK-N-AS cells (human neuroblastoma cell line) at different concentrations and quantified by the nuclear DNA fragmentation by flow cytometry analysis. PdL3 and PdL8 as well as the ligand precursors do not show any apoptosis inducing effects in Nalm-6 cells and SK-N-AS cells (see ESI†). AuL9 shows no apoptotic effect in Nalm-6 cells, but significant apoptosis induction by AuL9 is detected in SK-N-AS cells (Fig. 9A); therefore, the effect of AuL9 in SK-N-AS cells was further characterized.

Fig. 9 (A) AuL9 induces apoptosis in SK-N-AS cells. The cells were treated with different concentrations of AuL9 and incubated for 96 h. Nuclear DNA fragmentation was analyzed. (B) To exclude unspecific cytotoxic effects, such as necrotic cell death, the viability of SK-N-AS cells was determined by measurement of LDH release into the medium after 2 h of incubation with different concentrations of AuL9. No significant LDH release could be detected in cells treated with AuL9 up to a concentration of 100 μM. Values are given as mean% of DMSO control \pm SD (n=3). (C) The inhibition of proliferation of AuL9 treated SK-N-AS cells was measured after 48 h using the CASY Cell-Counter System. A significant inhibition of cell growth was observed at concentrations as low as 10 μM. Inhibition of proliferation is given in mean% of control \pm SD (n=3); *: $p<0.05\ vs.$ DMSO, t-test.

To exclude necrotic effects of **AuL9**, lactate dehydrogenase (LDH) leakage from SK-N-AS cells after 2 h incubation with **AuL9** was measured. LDH is released from the cell in case of necrosis and can be detected in the cell culture medium in case of loss of cell integrity and thus serves as a necrosis indicator. ⁵³ **AuL9** shows no significant non-specific cytotoxic effects on SK-N-AS cells in the relevant concentration range up to $100 \mu M$ (Fig. 9B).

In addition to apoptosis induction, it was tested whether **AuL9** can inhibit the proliferation of malignant cells. For this purpose, SK-N-AS cells were incubated with different concentrations of **AuL9** for 48 hours. The proliferation inhibition was determined by comparing the total cell number of vital cells of the DMSO control with the total cell number of vital cells of the treated cells. The results show that **AuL9** inhibits cell proliferation of SK-N-AS cells in a dose-dependent manner (Fig. 9C). A concentration of 50 µM **AuL9** causes nearly 100% inhibition of proliferation, indicating G1 arrest.

For the investigation of the mechanism of action of AuL9, the mitochondrial membrane potential of SK-N-AS cells was measured after 48 h incubation with AuL9. It was shown that the mitochondrion and thus the intrinsic apoptosis pathway plays at least a partial role in the effect of AuL9 (Fig. 10A).

To further characterize the role of mitochondria in AuL9induced apoptosis, the apoptosis pathway mediated by reactive oxygen species (ROS) was investigated. Therefore, N-acetylcysteine (NAC) as a known ROS inhibitor and H2O2, which belongs to the ROS, as a positive control was investigated. It was shown that apoptosis induction could be significantly inhibited by NAC. It can therefore be concluded that the generation of ROS plays a role in the AuL9-induced apoptosis (Fig. 10B). However, it is not possible in the present state to be sure how the ROS are generated and whether AuL9 directly leads to an increased ROS production or triggers pathways that result in the generation of ROS.

Overcoming cisplatin resistance

Cisplatin is a well-known chemotherapeutic agent for the treatment of many different types of cancer. 54 The development of resistance in tumor cells is a major problem in therapy and is usually the limiting factor in the cure of cancer patients.⁵⁵

Fig. 10 (A) The mitochondrial membrane potential in SK-N-AS cells was impaired by AuL15 treatment, which implicates mitochondrial pathway involvement in apoptosis induction. The mitochondrial membrane potential was measured by flow cytometric analysis in SK-N-AS cells after 48 h of incubation with different concentrations of AuL15 and staining with the cationic dye JC-1. Values are mean% of cells with low mitochondrial membrane potential \pm SD (n=3); *: p <0.05 vs. DMSO, t-test. B The induction of apoptosis in SK-N-AS cells in response to AuL15 treatment was shown to be dependent on the ROS mediated pathway. The cells were incubated for 72 h with 50 μ M H₂O₂ as a positive control or different concentrations of AuL15 with or without pretreatment of the cells with the ROS inhibitor N-acetylcysteine (NAC, 5 mM) 1.5 h prior to substance addition. Nuclear DNA fragmentation was analyzed by flow cytometric analysis. Values are mean% of apoptotic cells \pm SD (n = 3); *: p < 0.05 vs. DMSO, t-test.

Fig. 11 SK-N-AS and SK-N-AS cisplatin resistant cells were treated with different concentrations of AuL15 and incubated for 96 h. It is shown that AuL9 was also effective in inducing apoptosis in cisplatin resistant cells, thus overcoming resistance. 8.25 µM cisplatin has been used as a positive control to prove resistance. Nuclear DNA fragmentation was analyzed by flow cytometric analysis. Values are mean% of apoptotic cells \pm SD (n=3); *: p < 0.05 vs. DMSO, t-test.

Therefore, it is of great importance for drug development that new agents are able to overcome cytostatic drug resistance. In addition to SK-N-AS cells, AuL9 was tested on cisplatin resistant SK-N-AS cells and cisplatin resistance overcoming could be demonstrated (Fig. 11). In a previous characterization of the cisplatin resistant SK-N-AS cells, procaspase-8 under expression was shown.56 The cisplatin resistance overcoming of SK-N-AS cells indicates that procaspase-8 has a minor role in AuL9induced apoptosis.

Conclusion and outlook

A synthetic approach to a calix[4]imidazolinium macrocycle as saturated analog to a is presented. The synthesis of two new macrocyclic ligand systems, being bridged by ethylene groups and containing imidazoline (H₄L5/6) and imidazole moieties (H₄L8/9) are discussed. In addition, a novel bisimidazolinium ligand precursor (H2L3) is described. All complexes (Pd/PtL3, PdL5/6, Pd/PtL8, Au/PdL9) with their respective ligands synthesized in this work are not accessible via the direct metalation of the respective ligand, due to irreproducible or unreliable results, except for **AuL9**. Even the route *via* the silver salt transmetalation does not lead to reliable results. The silver complexes of the respective ligands could not be isolated, probably due to instability of the respective complexes. Therefore, a modified synthetic method has been established. Here, in situ transmetalation with silver oxide is used in combination with the metal precursor and an excess of sodium acetate as a mild base, resulting in the corresponding complexes. Furthermore, the complexes PdL3, PdL8, AuL9 and their respective ligands were tested for their ability to induce apoptosis on Naml-6 and SK-N-AS cells. According to the experiments performed, the data suggest that AuL9 is capable of inducing apoptosis in malignant cells via the mitochondrial and ROS pathway. However, so far, an effect could only be observed on SK-N-AS neuroblastoma cells. In addition, a relatively high dose of AuL9 is required to induce apoptosis in neuroblastoma cells, which could be challenging for clinical applicability. AuL9 is able to overcome resistance to cisplatin in

neuroblastoma cells (SK-N-AS) *in vitro*. Further characterization experiments would be required to determine the exact mechanism of action of **AuL9**, for example identification of molecular targets that are involved in the **AuL9** induced apoptosis, as well as the selectivity for cancer cells.

Experimental section

General procedures and analytical methods

Unless otherwise stated, all manipulations were performed under normal atmosphere without dried and degassed chemicals. All syntheses regarding the complexes were conducted under the exclusion of light. Every work-up was performed under normal atmosphere without dried and degassed chemicals; the complexes' work-ups were conducted in addition under the exclusion of light unless otherwise stated. Purification, in case of the Pt and Pd complexes, is achieved by dissolving the crude product in MeCN and filtering it through basic aluminum oxide to remove impurities. Acidic aluminum oxide promotes the decomposition of the complexes while pH-neutral aluminum oxide leads in smaller yields.6 All obtained complexes are air- and water stable; however, PtL3, PtL8 and AuL9 decompose after extensive exposition to light. Solvents were obtained water-free from a MBraun solvent purification system and stored over molecular sieves (3 Å). The procedures for novel compounds obtained during the synthetic approaches to the saturated macrocyclic ligand precursor, containing 2imidazoline moieties instead of imidazole, calix[4]imidazoli-N-benzyl-2-imidazoline, (2-imidazoline, methylenebis(1-benzyl-2-imidazolinium)dibromide, N^1, N^1, N^2, N^2 -tetrabenzylethane-1,2-diamine, tert-butyl (2-aminoethyl)carbamate, tert-butyl 2-imidazoline-1-carboxylate) are stated in the ESI.† N-Benzylethylenediamine (12),57-59 ethylenebis(trifluoromethanesulfonate) (4),60 1,1'-ethylene-di-2imidazoline $(1)^{23}$ and 1,1'-ethylenebis-1*H*-imidazolyl $(7)^{25,61}$ were synthesized according to literature procedures. All other reagents were purchased from commercial suppliers and used without further purification. NMR spectra were recorded on a Bruker Avance DPX 400 (1H-NMR, 400 MHz; 13C-NMR, 100 MHz; ¹⁹F-NMR, 376 MHz) and chemical shifts are given in δ values in ppm (parts per million) relative to TMS (tetramethylsilane) and reported relative to the residual signal of the deuterated solvent.62 Elemental analysis (C/H/N) were obtained by the Microanalytical Laboratory at Technische Universität München. Electrospray ionization mass spectrometry (ESI-MS) data were acquired on a Thermo Fisher Ultimate 3000 and with higher resolution (HR-ESI-MS) on Exactive Plus Orbitrap

Synthetic procedures

from Thermo Fisher.

Alkylbisimidazoline diiodide (2). 1 (5.00 g, 30.0 mmol, 1.00 eq.) is dissolved in MeCN (300 mL) and MeI (213 g, 1.50 mol, 50.0 eq.) is added. The resulting reaction mixture is heated to reflux for 4 h. After cooling to ambient temperature, all volatile compounds are removed *in vacuo*. The resulting crude material is redissolved in a small amount of MeCN (5 mL) and an off-

white solid is precipitated after the addition of Et₂O (40 mL). The crude material is collected via centrifugation and washed with (3 × 5 mL) Et₂O. After removal of all volatile compounds in vacuo, 2 is obtained as an off-white solid (11.1 g, 24.7 mmol, 82%). ¹H-NMR (400 MHz, DMSO-d₆) δ (ppm) = 8.54 (s, 2H, N-CH-N), 3.91 (s, 8H, CH₃-N-CH₂-CH₂), 3.70 (s, 4H, CH₂-CH₂), 3.12 (s, 6H, CH₃). ¹³C-NMR (101 MHz, DMSO-d₆) δ (ppm) = 159.12 (N-CH-N), 50.96 (C(backbone)), 48.70 (C(backbone)), 45.02 (C(CH₂-CH₂), 35.08 (CH₃). Elemental analysis: for C₁₀H₂₀I₂N₄ (%) anal. calc.: C: 26.68, H: 4.48, N: 12.45, found: C: 26.66, H: 4.48, N: 12.39.

Alkylbisimidazolinium hexafluorophosphate (H₂L3). 2 (100 mg, 222 μmol, 1.00 eq.) is dissolved in H₂O (1 mL) and added to a solution of NH₄PF₆ (217 mg, 1.33 mmol, 6.00 eq.) in H₂O (1 mL). The resulting white precipitate is collected, washed three times with H₂O (2 mL, 2 mL, 1 mL) and dried subsequently *in vacuo*. Without further purification, the titled compound H₂L3 is obtained as a white solid (98 mg, 202 mmol, 91%). ¹H-NMR (400 MHz, DMSO-d₆) δ (ppm) = 8.39 (s, 2H, N-CH-N), 3.88 (s, 8H, CH₃-N-CH₂-CH₂), 3.67 (s, 4H, CH₂-CH₂), 3.11 (s, 6H, CH₃). ¹³C-NMR (101 MHz, DMSO-d₆) δ (ppm) = 158.77 (N-CH-N), 50.36 ($C_{\rm (backbone)}$), 48.12 ($C_{\rm (backbone)}$), 44.55 ($C_{\rm H_2}$ -CH₂), 34.43 ($C_{\rm H_3}$). ¹⁹F-NMR (376 MHz, DMSO-d₆) δ (ppm) = -70.15 (d, ¹ $J_{\rm P-F}$ = 713 Hz, PF₆⁻). Elemental analysis: for C₁₀H₂₀F₁₂N₄P₂ (%) anal. calc.: C: 24.70, H: 4.15, N: 11.52, found: C: 24.28, H: 4.01, N: 11.17.

Calix[4](-Et-Et-)imidazoliniumtrifluoromethanesulfonate (H₄L5). 1 (1.00 g, 6.17 mmol, 2.00 eq.) is dissolved in dry MeCN (1.5 L), cooled to -45 °C and a solution of 4 (2.02 g, 6.20 mmol,2.01 eq.) in dry MeCN (50 mL) is added dropwise over 6 h. After the addition, the reaction mixture is stirred for 72 h at ambient temperature. All volatile compounds are removed in vacuo and the resulting crude material is dried subsequently in vacuo. Without further purification the titled compound H₄L5 is obtained as an off-white solid (1.50 g, 1.54 mmol, 50%). Note: everything is conducted under inert conditions. ¹H-NMR (400 MHz, DMSO-d₆) δ (ppm) = 8.46 (s, 4H, N-C*H*-N), 3.95 (s, 16H, $CH_{2(bridge/backbone)}$, 3.74 (s, 16H, $CH_{2(bridge/backbone)}$). ¹³C-NMR (101 MHz, DMSO-d₆) δ (ppm) = 159.16 (N-CH-N), 120.80 (q, $^{1}J_{19F^{-}13C} = 320 \text{ Hz}, \text{ OTf}^{-}), 48.15 (CH_{2(\text{bridge/backbone})}), 44.54$ $(CH_2-CH_{2(bridge/backbone)})$. ¹⁹F-NMR (376 MHz, DMSO-d₆) δ (ppm) = -77.74 (CF₃). Elemental analysis for C₂₄H₃₆N₈O₁₂F₁₂S₄ (%) anal. calc.: C 29.27; H 3.68; N 11.38; S 13.02 found: C 29.37; H 3.67; N 11.01; S 13.12.

Calix[4](-Et-Et-)imidazoliniumhexafluorophosphate H₄L6). H₄L5 (300 mg, 304 μmol, 1.00 eq.) is dissolved

(H₄L6). H₄L5 (300 mg, 304 μmol, 1.00 eq.) is dissolved in H₂O (50 mL) and added to a solution of NH₄PF₆ (223 mg, 1.37 mmol, 4.50 eq.) in H₂O (50 mL). The resulting white precipitate is collected, washed three times with H₂O (10 mL, 7 mL, 5 mL), Et₂O (3 mL, 2 mL) and dried subsequently *in vacuo*. Without further purification, the titled compound H₄L6 is obtained as a white solid (240 mg, 248 μmol, 81%). However, a small amount of OTf⁻ is still detectable in the ¹⁹F-NMR. ¹H-NMR (400 MHz, DMSO-d₆): δ (ppm) = 8.44 (s, 4H, N-CH-N), 3.93 (s, 16H, CH_{2(backbone)}/CH_{2,(bridge)}), 3.72 (s, 16H, CH_{2,(bridge)}/CH_{2,(bridge)}). ¹H-NMR (400 MHz, CD₃CN): δ (ppm) = 7.98-7.82 (m, 4H, N-CH-N), 4.00–3.82 (m, 16H, CH_{2,(backbone)}/CH_{2,(bridge)}), 3.73–3.65

(m, 16H, $CH_{2,(bridge)}/CH_{2,(backbone)}$). ¹⁹F-NMR (376 MHz, CD_3CN): δ (ppm) = -72.45 (d, ${}^1J_{P-F}$ = 713 Hz, PF_6^-). ESI-MS: m/z = calc. for $[\mathbf{H_4L6}-PF_6^-]^+$: 823.20 ($[\mathbf{M}-PF_6^-]^+$); found: 822.94; calc. for $[\mathbf{H_4L6}-2PF_6^-]^+$: 339.11 ($[\mathbf{H_4L6}-2PF_6^-]^+$); found: 339.12.

Calix[4](-Et-Et-)imidazoliumtrifluoromethanesulfonate (H₄L8). 7 (1.00 g, 6.17 mmol, 2.00 eq.) is dissolved in dry MeCN (1.5 L), cooled to $-30 \, ^{\circ}$ C and a solution of 4 (2.02 g, 6.20 mmol, 1.5 L)2.01 eq.) in dry MeCN (100 mL) is added dropwise over 5 h. After the addition, the reaction mixture is stirred for 72 h at ambient temperature. All volatile compounds are removed in vacuo and the resulting crude material is washed eight times with cold acetone (10 mL, 5 mL, 5 mL, 3 mL, 3 mL, 2 mL, 2 mL, 1 mL) and dried subsequently in vacuo. Without further purification, the titled compound H₄L8 is obtained as a white solid (1.50 g, 1.54 mmol, 50%). ¹H-NMR (400 MHz, CD₃CN) δ (ppm) = 8.57 (t, $^{4}J = 1.6 \text{ Hz}, 4H, N-CH-N), 7.39 (d, ^{4}J = 1.7 \text{ Hz}, 8H, CH), 4.71 (s, 1.5)$ 16H, CH₂). ¹³C-NMR (101 MHz, CD₃CN) δ (ppm) = 138.49 (N-CH-N), 124.49 (HC=CH), 121.80 (q, ${}^{1}J_{19F^{-}13C} = 320 \text{ Hz}$, OTf⁻), 50.14 (CH_2 - CH_2). ¹⁹F-NMR (376 MHz, CD_3CN) δ (ppm) = -79.32 (CF₃). ¹H-NMR (400 MHz, DMSO-d₆) δ (ppm) = 9.00 (t, ⁴J = 1.7 Hz, 4H, N-CH-N), 7.57 (d, 4J = 1.6 Hz, 8H, CH), 4.74 (s, 16H, CH₂). ¹³C-NMR (101 MHz, DMSO-d₆) δ (ppm) = 137.08 (N-CH-N), 123.28 (HC=CH), 120.66 (q, ${}^{1}J_{19F^{-}13C} = 320 \text{ Hz, OTf}^{-}$), 49.24 (CH₂-CH₂). Elemental analysis for C₂₄H₂₈N₈O₁₂F₁₂S₄ (%) anal. calc.: C 29.54; H 2.84; N 11.54; S 13.13 found: C 29.54; H 2.84; N 11.54; S 13.25. ESI-MS: $m/z [H_4L8-4OTf^-]^{4+}$ calc.: 95.06, found: 94.91, [H₄L8-3OTf⁻]³⁺ calc.: 176.39, found 176.36, [H₄L8-2OTf⁻]²⁺ calc.: 339.07, found: 339.22, [H₄L8-1OTf⁻]¹⁺ calc.: 827.03, found 826.93.

Calix[4](-Et-Et-)imidazoliumhexafluorophosphate (H₄L9). H_4L8 (3.20 g, 3.28 mmol, 1.00 eq.) is dissolved in H_2O (300 mL) and added to a solution of NH₄PF₆ (3.20 g, 19.66 mmol, 6.00 eq.) in H₂O (50 mL). The resulting white precipitate is collected, washed three times with H2O (10 mL, 7 mL, 5 mL) and dried subsequently in vacuo. Without further purification, the titled compound H₄L9 is obtained as a white solid (2.80 g, 2.85 mmol, 88%). ¹H-NMR (400 MHz, CD₃CN) δ (ppm) = 8.44 (t, ⁴J = 1.6 Hz, 4H, N-CH-N), 7.33 (d, ${}^{4}J = 1.7$ Hz, 8H, CH), 4.70 (s, 16H, CH₂). ¹⁹F-NMR (376 MHz, CD₃CN) δ (ppm) = -72.30 (d, ${}^{1}J_{\text{FP}}$ = 713 Hz, PF_6^-). ¹H-NMR (400 MHz, DMSO-d₆) δ (ppm) = 9.00 (s, 4H, N-CH-N), 7.55 (d, ${}^{4}J = 1.6$ Hz, 8H, CH), 4.73 (s, 16H, CH₂). ${}^{13}C$ -NMR (101 MHz, DMSO-d₆) δ (ppm) = 137.26 (N-CH-N), 123.49 (HC=CH), 49.44 (CH2-CH2). Elemental analysis for C₂₀H₂₈N₈F₂₄P₄ (%) anal. calc.: C 25.01; H 2.94; N 11.67; S 0.00 found: C 25.08; H 2.90; N 11.31; S 0.00.

Pd[C^{Et}C_{imi}(Me)₂C^{Et}C_{imi}(Me)₂]hexafluorophosphate (PdL3). Ag₂O (150 mg, 648 μmol, 1.05 eq.) is added to a solution of H₂L3 (300 mg, 617 μmol, 1.00 eq.) and NaOAc (202 mg, 2.47 mmol, 4.00 eq.) in dry MeCN (15 mL) and stirred for 1 h at ambient temperature, followed by the addition of Pd(OAc)₂ (145 mg, 648 μmol, 1.05 eq.). The resulting reaction mixture is heated to 80 °C for 3 d. After cooling to ambient temperature, the reaction mixture is filtered over a short plug of basic aluminum oxide. The filter column is eluted with MeCN (20 mL) and all volatile compounds are removed *in vacuo*. The resulting crude material is resuspended in MeCN (5 mL) and centrifuged. Upon the addition of Et₂O (20 mL) to the supernatant, a white solid is

precipitated. The crude material is collected via centrifugation, washed with Et₂O (3 \times 5 mL), redissolved in MeCN (5 mL) and precipitated with Et₂O (15 mL). After drying in vacuo, the titled compound PdL3 is obtained as an off-white solid (140 mg, 178 μmol, 29%). Single crystals suitable for SC-XRD were obtained by slow diffusion of Et₂O into MeCN solution of PdL3. ¹H-NMR (400 MHz, CD₃CN) δ (ppm) = 4.32-4.22 (m, 4H, C $H_{2(backbone)}$), 3.71-3.51 (m, 20H, CH_2-CH_2 , $CH_{2(backbone)}$), 2.97 (s, 12H, CH_3). ¹³C-NMR (101 MHz, CD₃CN) δ (ppm) = 195.6 (N-C-N), 51.72 $(C_{\text{(bridge)}}, C_{\text{(backbone)}})$, 51.26 $(C_{\text{(bridge)}}, C_{\text{(backbone)}})$, 46.5 (CH_2) , 37.62 (CH₃). ¹⁹F-NMR (376 MHz, CD₃CN): δ (ppm) = -72.94 (d, $^{1}J_{P-F} = 706 \text{ Hz}, PF_{6}$). $^{1}H-NMR (400 \text{ MHz}, DMSO-d_{6}) \delta (ppm) =$ 4.35-4.13 (m, 4H, $CH_{2(backbone)}$), 3.82-3.57 (m, 20H, CH_2 - CH_2 , $CH_{2(backbone)}$, 2.95 (s, 12H, CH_3). ¹³C-NMR (101 MHz, DMSO-d₆) δ (ppm) = 194.29 (N-C-N), 50.94 ($C_{\text{(bridge)}}$, $C_{\text{(backbone)}}$), 50.56 $(C_{\text{(bridge)}}, C_{\text{(backbone)}}), 45.76 (CH_2), 37.17 (CH_3)$. Elemental analysis: for C₂₀H₃₆F₂₄N₈P₄Pd₁ (%) anal. calc.: C: 30.60, H: 4.62, N: 14.28, found: C: 30.93, H: 4.55, N: 14.14, S: 0.00. HR-ESI-MS: m/z $[PdL3-2PF_6]^{2+}$ calc.: 247.1044, found: 247.1039, $[PdL3-PF_6]^{-1}$ calc.: 639.1735, found: 639.1720.

Pt[C^{Et}C_{imi}(Me)₂C^{Et}C_{imi}(Me)₂]hexafluorophosphate Ag_2O (150 mg, 648 µmol, 1.05 eq.) is added to a solution of H_2L3 (300 mg, 617 μmol, 1.00 eq.) and NaOAc (202 mg, 2.47 mmol, 4.00 eq.) in dry MeCN (15 mL) and stirred for 1 h at ambient temperature, followed by the addition of PtCl₂ (145 mg, 648 μ mol, 1.05 eq.). The resulting reaction mixture is heated to 80 $^{\circ}$ C for 3 d. After cooling to ambient temperature, the reaction mixture is filtered over a short plug of basic aluminum oxide. The filter column is eluted with MeCN (20 mL) and all volatile compounds are removed in vacuo. The resulting crude material is resuspended in MeCN (5 mL) and centrifuged. Upon the addition of Et₂O (20 mL) to the supernatant, a white solid is precipitated. The crude material is collected *via* centrifugation, washed with Et₂O (3 \times 5 mL) and redissolved in MeCN (5 mL) and precipitated with Et₂O (15 mL). After drying in vacuo, the titled compound PtL3 is obtained as an off-white solid (23 mg, 26 μmol, 4%). Single crystals suitable for SC-XRD were obtained by slow diffusion of Et2O into MeCN solution of PtL3. Note; a clean EA could not be obtained, and the NMR includes impurities. ¹H-NMR (400 MHz, CD₃CN) δ (ppm) = 4.35–4.26 (m, 4H, $CH_{2(backbone)}$, 3.72–3.51 (m, 20H, CH_2 – CH_2 , $CH_{2(backbone)}$), 2.94 (s, 12H, CH₃). ¹³C-NMR (101 MHz, CD₃CN) δ (ppm) = 188.38 (N-C-N), 51.47 (d, C_(bridge), C_(backbone)), 46.39 (CH₂), 37.44 (CH_3) .

Pd[(cC^{Et}CC^{Et}C_{imi})OTf] (PdL5). Ag₂O (155 mg, 670 μmol, 2.20 eq.) is added to a solution of H_4L5 (300 mg, 305 μmol, 1.00 eq.) and NaOAc (200 mg, 2.42 mmol, 8.00 eq.) in dry MeCN/DMSO (12 mL 1:1) and stirred for 1 h at ambient temperature, followed by the addition of $Pd(OAc)_2$ (71.8 mg, 320 μmol, 1.05 eq.). The resulting reaction mixture is heated to 80 °C for 3 d and is filtered, after cooling to ambient temperature, over a short plug of basic aluminum oxide. The filter column is eluted with MeCN (100 mL) and all volatile compounds are removed *in vacuo*. The resulting oily solution (still approx. 6 mL of DMSO remaining) is resuspended in MeCN (6 mL) and centrifuged. Upon the addition of Et_2O (25 mL) to the supernatant, a brown/black solid is precipitated. After another addition of Et_2O (120 mL) a white

solid is precipitated. The white crude material is collected via centrifugation, washed with Et $_2$ O (3 \times 5 mL) and redissolved in MeCN (5 mL). After purification [3 times dissolving in MeCN (4 mL) and precipitating with Et $_2$ O (\sim 15 mL)] and removing all volatile compounds in vacuo, the titled compound PdL5 is obtained as an off-white solid (7.00 mg, 8.87 µmol, 3%). 1 H-NMR (400 MHz, CD $_3$ CN): δ (ppm) = 4.10–4.00 (m, 8H, CH $_2$,(bridge)), 3.76–3.54 (m, 16H, CH $_2$,(backbone)), 3.52–3.45 (m, 8H, CH $_2$,(bridge)). 1 C-NMR (101 MHz, CD $_3$ CN): δ (ppm) = 191.3 (N–C–N), 51.0 (CH $_2$,(bridge)/CH $_2$,(backbone)), 47.4 (CH $_2$,(backbone)/CH $_2$,(bridge)). 1 F-NMR (376 MHz, CD $_3$ CN): δ (ppm) = -79.33 (CF $_3$). ESI-MS: m/z = calc. for [PdL5–OTf $_1$ *: 639.13 ([PdL5–OTf $_1$ *); found: 639.44; calc. for [PdL5–2OTf $_1$ *: 245.09 ([M–2OTf $_1$ *); found: 245.20.

Pd[(cCEtCCEtC_{imi})PF₆] (PdL6). PdL6 is synthesized analog to PdL5; by converting H_4L6 (230 mg, 238 µmol, 1.00 eq.) with Ag₂O (121 mg, 522 μmol, 2.20 eq.) in dry MeCN (4 mL) while stirring for 1 h at ambient temperature, followed by the addition of NaOAc (156 mg, 1.90 mmol, 8.00 eq.), Pd(OAc)₂ (56.0 mg, 249 μmol, 1.05 eq.) and is heated at 75 °C for 4 d. After purification [3 times dissolving in MeCN (4 mL) and precipitating with Et₂O (~15 mL)] and removing all volatile compounds, PdL6 is obtained as a pale-yellow solid (85.0 mg, 109 µmol, 46%). ¹H-NMR (400 MHz, CD₃CN): δ (ppm) = 4.13-4.02 (m, 8H, C $H_{2,\text{(bridge)}}$), 3.78-3.60 (m, 16H, $CH_{2,(backbone)}$), 3.52-3.46 (m, 8H, $CH_{2,(bridge)}$). ¹⁹F-NMR (376 MHz, CD₃CN): δ (ppm) = -72.78 (d, ${}^{1}J_{P31-F19}$ = 707 Hz, PF₆) elemental analysis for C₂₀H₃₂F₁₂N₈P₂Pd (%) anal. calc.: C 30.76; H 4.13; N 14.13; found: C 29.50; H 4.07; N 14.35. ESI-MS: $m/z = \text{calc. for } [PdL6-PF_6^-]^+: 635.14 ([M-PF_6^-]^+); \text{ found:}$ 635.21. HR-ESI-MS: m/z [PdL6-2PF₆⁻]²⁺ calc.: 245.0887, found: 245.0890, $[PdL6 + H_2O-2PF_6]^{2+}$ calc.: 254.0940, found: 254.0944, [**PdL6**-PF₆⁻]⁺ calc.: 635.1422, found: 635.1425, [**PdL6** $+ H_2O-PF_6^{-}$ calc.: 653.1527, found: 653.1534.

Pd[($cC^{Et}CC^{Et}C$)OTf] (PdL8). Ag₂O (74.7 mg, 322 μ mol, 1.05 eq.) is added to a solution of H₄L8 (320 mg, 307 µmol, 1.00 eq.) and NaOAc (202 mg, 2.46 mmol, 4.00 eq.) in dry MeCN (15 mL) and stirred for 1 h at ambient temperature, followed by the addition of Pd(OAc)₂ (72.4 mg, 322 µmol, 1.05 eq.). The resulting reaction mixture is heated to 80 °C for 4 d. After cooling to ambient temperature, the reaction mixture is filtered over a short plug of basic aluminum oxide. The filter column is eluted with MeCN (50 mL) and all volatile compounds are removed in vacuo. The resulting crude material is resuspended in MeCN (5 mL) and centrifuged. Upon the addition of Et₂O (20 mL) to the supernatant, a white solid is precipitated. The crude material is collected via centrifugation, washed with Et₂O (3 \times 5 mL) and redissolved in MeCN (5 mL). After the precipitation with Et₂O (15 mL) and drying in vacuo, the titled compound PdL8 is obtained as an off-white solid (119 mg, 153 μmol, 50%). ¹H-NMR (400 MHz, CD₃CN) δ (ppm) = 7.20 (s, 8H, CH), 5.02– 4.93 (m, 8H, CH₂), 4.47-4.39 (m, 8H, CH₂). ¹³C-NMR (101 MHz, $CD_3CN) \delta (ppm) = 165.84 (N-C-N), 123.77 (CH), 49.11 (s, CH₂ CH_2$). ¹H-NMR (400 MHz, DMSO-d₆) δ (ppm) = 7.52 (s, 8H, CH), 5.05-4.95 (m, 8H, CH₂), 4.52-4.42 (m, 8H, CH₂). ¹³C-NMR (101 MHz, DMSO-d₆) δ (ppm) = 163.80 (N-C-N), 123.32 (CH), 48.14 (CH_2-CH_2) . Elemental analysis for $C_{20}H_{28}N_8F_{24}P_4 + 1$ MeCN (%) anal. calc.: C 35.07; H 3.31; N 15.33; S 7.80 found: C 35.26; H 3.21; N 15.73; S 7.82. HR-ESI-MS: m/z [PdL8-2OTf⁻]²⁺ calc.: 241.0574, found: 241.0570, [**PdL8**-OTf⁻]⁺ calc.: 631.0674, found: 631.0658.

Pd[(cC^{Et}CC)PF₆] (PdL9). PdL8 (95 mg, 122 μmol, 1.00 eq.) is dissolved in H₂O (35 mL), after the addition of NH₄PF₆ (50.0 mg, 305 μmol, 2.5 eq.) a white precipitate is collected *via* centrifuge and washed three times with H₂O (5 mL, 3 mL, 3 mL) and Et₂O (10 mL, 5 mL, 3 mL). After drying *in vacuo*, the titled compound PdL9 is obtained as an off-white solid (39 mg, 50 μmol, 41%). Single crystals suitable for SC-XRD were obtained by slow diffusion of Et₂O into MeCN solution of PdL8. ¹H-NMR (400 MHz, CD₃CN) δ (ppm) = 7.22 (s, 8H, CH), 4.97 (m, 8H, CH₂), 4.43 (m, 8H, CH₂). ¹⁹F-NMR (376 MHz, CD₃CN) δ (ppm) = -72.93 (d, ${}^{1}J_{\rm FP} = 713$ Hz, PF₆⁻). HR-ESI-MS: m/z [PdL9-2PF₆⁻]²⁺ calc.: 241.0574, found: 241.0570, [PdL9-PF₆⁻]⁺ calc.: 627.0796, found: 627.0782.

Pt[($cC^{Et}CC^{Et}C$)OTf] (PtL8). Ag₂O (209 mg, 900 μ mol, 2.20 eq.) is added to a solution of H₄L8 (400 mg, 410 µmol, 1.00 eq.) and NaOAc (202 mg, 2.46 mmol, 4.00 eq.) in dry MeCN (30 mL) and stirred for 1 h at ambient temperature, followed by the addition of Pt(MeCN)₂Cl₂ (156 mg, 450 µmol, 1.10 eq.). The resulting reaction mixture is heated to 80 °C for 3 d and is filtered, after cooling to ambient temperature, over a short plug of basic aluminum oxide. The filter column is eluted with MeCN (50 mL) and all volatile compounds are removed in vacuo. The resulting crude material is resuspended in MeCN (5 mL) and centrifuged. Upon the addition of Et₂O (20 mL) to the supernatant, a white solid is precipitated. The crude material is collected *via* centrifugation, washed with Et₂O (3 \times 5 mL) and redissolved in MeCN (5 mL). After the precipitation with Et₂O (15 mL) and drying in vacuo, the titled compound PtL8 is obtained as an off-white solid (90 mg, 103 μmol, 25%). H-NMR (400 MHz, CD₃CN) δ (ppm) = 7.19 (s, 8H, CH), 5.11-4.94 (m, 8H, CH₂), 4.50-4.38 (m, 8H, CH₂). ¹H-NMR (400 MHz, DMSO-d₆) δ (ppm) = 7.49 (s, 8H, CH), 5.06-4.97 (m, 8H, CH₂), 4.54-4.44 (m, 8H, CH₂). ¹³C-NMR (101 MHz, CD₃CN) δ (ppm) = 159.39 (N-CH-N), 123.58 (HC=CH), 48.86 (CH_2-CH_2) . ¹⁹F-NMR (376 MHz, CD₃CN) δ (ppm) = -79.27 (CF₃). HR-ESI-MS: m/z [PtL8-2OTf⁻]²⁺ calc.: 285.5881, found: 285.5864, [PtL8-OTf⁻] calc.: 720.1287, found: 720.1264.

Au[(cC^{Et}CC^{Et}C)PF₆] (AuL9). H₄L8 (500 mg, 458 μmol, 1.00 eq.), $KAuCl_4 \times 2H_2O$ (209 mg, 505 μ mol, 1.05 eq.), and NaOAc (197 mg, 2.41 mmol, 5.00 eq.) are suspended in dry DMSO (5 mL). The resulting reaction mixture is stirred for 5 h at 100 °C and filtered at ambient temperature. MeCN (5 mL) is added to the filtrate. After the addition of Et₂O (30 mL) to the solution, white solid precipitated. It is washed with MeCN (3 \times 5 mL) and DCM (2 \times 5 mL) and after the removal of all volatiles in vacuo, the solid is dissolved in H₂O (2 mL) and added dropwise to a solution of NH₄PF₆ (353 mg, 2.17 mmol, 4.00 eq.) in H₂O (5 mL). The resulting white precipitate is collected and washed with H_2O (3 × 5 mL) and after removal of all volatiles in vacuo, the titled compound AuL9 (230 mg, 228 mmol, 47%) is obtained as a white solid. ¹H-NMR (400 MHz, CD₃CN) δ (ppm) = 7.47 (s, 8H, CH), 4.89-4.77 (m, 8H, CH₂), 4.76-4.66 (m, 8H, CH₂). ¹³C-NMR (101 MHz, CD₃CN) δ (ppm) = 146.03 (N-CH-N), 125.92 (HC=CH), 48.58 (CH₂-CH₂). Elemental analysis for $C_{20}H_{24}$ - $AuF_{18}N_8P_3 \times 0.1 \text{ MeCN (\%)}$ anal. calc.: C 24.62; H 2.70; N 11.11; S 0.00 found: C 24.82; H 2.78; N 11.15; S 0.57. HR-ESI-MS: m/z [AuL9–3PF₆ $^-$]³⁺ calc.: 191.0591, found: 191.0587, [AuL9–PF₆ $^-$]⁺ calc.: 863.1068, found: 863.1038.

Conflicts of interest

There are no conflicts to declare.

Acknowledgements

All authors thank Prof. Dr T. Simon (University Cologne) for providing the SK-N-AS cell line, Dr Seeger for providing the Nalm-6 cell line. A. Prokop thanks the Dr. Kleist Foundation (Berlin), Foundation David (Cologne), Koch Foundation (Berlin) and Blankenheimerdorf e.V. (Eifel) for the financial support in the biological studies. Further thanks go to A. Gradenegger, F. Tschernuth from Prof. Dr S. Inoue, and C. Hoefer for synthetic support of the compound H₄L8 and Patrick Mollik for HR-ESI-MS measurements. Thanks also go to Rea Sangiovanni for the graphical abstract.
