Keto–enol equilibrium: stable tautomers of *ortho*-, *meta*-, and *para*-hydroquinones in large aromatics†

 Vincent Silber,  Christophe Gourlaouen * and Romain Ruppert *

The synthesis of [6]helicene *para*-quinone starting from the 1,4-dimethoxy-[6]helicene derivative is presented. The demethylation reaction with boron tribromide led to unexpected results. Instead of the expected *para*-hydroquinone, the diketone tautomeric form was isolated. In contrast to the 1,4-hydroquinone and 1,4-dihydroxynaphthalene, the stable tautomers for the [4] and [6]helicenes were the aromatic diketones. These experimental results were corroborated by calculations. Additional calculations showed that these tautomeric species were indeed the stable forms of 1,4 and 1,3-hydroquinones when present in larger aromatics, in drastic contrast with 1,2-dihydroxy-aromatics (known as catechol).

Introduction

[*n*]Helicenes are well-known molecules with the smallest one being first synthesised at the beginning of the twentieth century,¹ and the seminal articles of Newman gave a new impulse to the field.² The helicenes were prepared by various synthetic methodologies, with photochemical dehydrogenative cyclisations of stilbene derivatives or metal-catalysed cyclisations being widely used reactions. Very long helicenes and sophisticated structural modifications of helicenes have been described in the last twenty years.³ More recently, with the aim of varying the redox or photochemical properties of these molecules, various functionalities were introduced. In particular, metal-based organometallic derivatives were prepared and studied for their circularly polarised luminescence properties.⁴ Other redox-active compounds containing pyridinium units have also been recently described.⁵ The quinone–hydroquinone redox system is widely studied because it is present in many biological redox mediators or cellular cofactors. The naphthoquinones or anthraquinones are generally functionalized and in some case the unexpected 1,4-diketo tautomeric form of the corresponding reduced 1,4-hydronaphthoquinones or 1,4-hydroanthraquinones were isolated and characterised.⁶ This unexpected tautomeric 1,4-diketo form was also found during oxidative coupling of 2-hydroxyanthracene to form BINOL derivatives by the group of Shinokubo.⁷ Generally BINOL derivatives do not exhibit keto–enol tautomerism due to instability of the diketones. However, steric hindrance and a large conversion barrier was invoked to explain the stability of the

diketo tautomer. More than twenty years ago, many helicenic quinone compounds have been prepared by the group of T. J. Katz.⁸ In these seminal contributions, several large π -conjugated helicene-1,4-quinones were obtained and some of them aggregated to form even larger helical entities.⁹ These helicenes were generally obtained by Diels–Alder cyclisation in good yields.¹⁰ These quinones were initially prepared to study, after mono-electronic reduction, the electronic delocalisation through the fused aromatics of the helicene. In several reports, the generation of the 1,4-hydroquinone moiety was proposed as intermediate, but not fully characterised. In addition, notably during the alkylation of these hydroquinones with alcohols in acidic media, the presence of the dione tautomers as intermediates was suggested. Later, the group of Diederich described the synthesis and study of functionalised [6]helicenes containing an *ortho*-quinone moiety at one extremity of the π -conjugated molecules (see Scheme 1).¹¹ These compounds were prepared to check their optical switching properties upon reduction of the quinones to their radical-anions, or complexation of the catechol units by metal ions. The last steps during the synthesis of these *ortho*-quinone helicenes consisted of demethylation of the 1,2-dimethoxy derivative to the 1,2-dihydroxy derivative (the catechol) and oxidation to the *ortho*-quinone. In these reports, the 1,2-hydroquinones were fully characterised by ¹H and ¹³C NMR as the dihydroxy tautomers.

Results and discussion

During the course of our work on helicene–porphyrin conjugates, we prepared helicenic compounds containing electron rich methoxy substituents located at one extremity of the conjugated aromatic.¹² The desired [6]helicenic starting materials were prepared by usual synthetic procedures described for these types of compounds.¹³ The presence of the two methoxy substituents led to a small decrease of the photochemical cyclisation yield in the last step (52% instead of 76% for unsubstituted aromatics in general). The synthesis of **1** was reported earlier,¹² but is shown again here, because the lithiation of **1** led also to **2** as side-product after reaction with electrophiles (Scheme 2).

We were not able to obtain single crystals of helicene **2**, but could grow single crystals of **1** suitable for X-ray analysis. The structure was solved (see Fig. 1) and the exact positions of the two methoxy groups was therefore unambiguously confirmed. Compound **1** crystallised in the space group $P\bar{1}$ and both enantiomers were present in the unit cell. All molecules were “isolated” and no particular π – π stacking was observed in the structure.

The two enantiomers of helicene **1** were separated by preparative chiral HPLC and their properties determined. The ECD spectra of the enantiomers are typical of [6]helicenes (see Fig. 2) and the measured $[\alpha]_D^{25}$ were also similar to reported values (± 2850 , 3050, 3800, and 10 000 at 589, 578, 546, and 436 nm respectively, in dichloromethane, $c = 0.21$).

The bromo-dimethoxy derivative **1** of the [6]helicene was the starting compound for further functionalization. After bromine–lithium exchange, addition of the electrophiles always afforded the desired products, together with variable amounts of debrominated dimethoxy[6]helicene **2** as side-product. Compound **2** could alternatively be prepared by following the same procedure as for the synthesis of **1**, but without the bromine substituent in the starting material. Compound **2** was then reacted with BBr_3 , the classical reagent used to demethylate methoxyaromatics. To our surprise, the expected *para*-hydroquinone **3** was never isolated after this reaction. Instead, the isomeric reduced form **4** and the oxidized form of the hydroquinone (the *para*-quinone **6**) were isolated as sole products (see Scheme 3). The mono-ethoxylated product **5** was formed in our initial attempt, because non-distilled dichloromethane (containing less than 1% of ethanol as stabilising agent) was used for the work-up and chromatographic separations. The addition of alcohols in acidic media at room

Fig. 1 X-ray structure of the starting bromo-dimethoxy-[6]helicene **1**, only one enantiomer shown (CCDC no. 2092869†).

temperature was described earlier for phenolic helicenic compounds (the so-called Russig–Laatsch reaction).¹⁴ Using distilled dichloromethane the reaction gave only two products, the reduced form **4** and the quinone **6**, and again no hydroquinone tautomer **3**. The presence of quinone **6** was due to oxidation of **4** by air during work-up and chromatography.

The structures of compounds **4** and **6** could be easily deduced from the ^1H and ^{13}C NMR spectra. For *para*-quinone **6**, only aromatic protons were observed, no sp^3 carbons were found in the ^{13}C spectrum, and the two $^{13}\text{C}=\text{O}$ signals were located at 185.2 and 185.6 ppm (the chemical shift of the $^{13}\text{C}=\text{O}$ signal of 1,4-benzoquinone is 187 ppm). For the second compound **4**, the four CH_2 protons next to the two carbonyl functions were non-equivalent because this [6]helicene is chiral, and four well-separated ddd signals were observed between 3 and 1.7 ppm in the ^1H NMR spectrum (see Fig. 3, insert). In the ^{13}C NMR spectrum, two CH_2 carbons (DEPT 135) were found at 35.8 and 38.3 ppm and the two $^{13}\text{C}=\text{O}$ signals were found at 195.9 and 196.7 ppm. These are values characteristic of ketones (acetophenone $^{13}\text{C}=\text{O}$ signal at 195.7 ppm, or tetralone $^{13}\text{C}=\text{O}$ signal at 197.8 ppm) and very different from the measured values for the two $^{13}\text{C}=\text{O}$ carbons of quinone **6**.

Wondering if the stability of this tautomer was specific to these large [6]helicenes, we started to check the products obtained after the demethylation reaction of other 1,4-dimethoxy aromatics, notably smaller fused aromatics. Under the same experimental conditions, the 1,4-dimethoxynaphthalene **7** was treated with boron tribromide and as expected the 1,4-dihydroxynaphthalene **8** was isolated together with the 1,4-naphthoquinone **10** (see Scheme 4). The diketone **9** was known because the 1,4-dihydroxynaphthalene **8** and the diketone **9** are two tautomers which are in equilibrium. However, at room

temperature and under neutral conditions, the phenolic form is the stable form and the diketone **9** is not present.

The diketone **9** can be isolated from very acidic media¹⁵ or by melting the solid at high temperature.¹⁶ Both conditions (acidic medium or elevated temperatures) were very different from the mild experimental procedures used for our demethylation and the slightly basic treatment to neutralise boron tribromide should highly favor the phenolic form. This was true for the naphthalene derivative, but the opposite was found for the [6] helicenic aromatic for which only the diketone form **4** was

isolated. Helicenic quinones were often described in the literature and when the authors had to formulate the reduced forms (as an intermediate in various reactions), they always described them as the phenolic form.¹⁴ Puzzled by our observations, we also checked the dimethoxy derivative **11** of a compound containing four fused aromatic rings. Again, under the same experimental conditions, only two products were isolated from this reaction, *i.e.* the diketone **12** and the oxidised form, quinone **14** (see Scheme 5). It should be emphasised that compound **12** was quite rapidly oxidised to quinone **14** in solution. Consequently, the NMR spectra of **12** were always polluted by small amounts of quinone **14** (see ESI†).

The ^1H NMR spectrum of the compound **12** confirmed the diketone structure because two CH_2 resonances were observed at 3.31 and 3.52 ppm; the molecule racemizes too rapidly and the two protons of each CH_2 group were now equivalent. The $^{13}\text{C}=\text{O}$ signals were found at 195.1 and 202.1 ppm for diketone **12** and at 185.3 and 188.5 ppm for quinone **14**.

Clearly, the tautomeric equilibrium varied with the length of the aromatic 1,4-hydroquinones. The phenolic form was present for small aromatics whereas in the case of larger fused aromatics like these helicenes, the diketone was the major (and sole) tautomer found for the reduced forms of the *para*-quinones. These experimental findings were somehow counterintuitive for synthetic chemists because a loss of aromaticity is involved. This prompted us to examine the energy differences involved in these tautomeric equilibria. According to DFT calculations, the tautomeric equilibrium is displaced towards the diketone derivative for all compounds presenting a number of fused aromatic rings equal or greater than two (see Table 1).

This observation is consistent with experimental results, as shown by Thomson,¹⁶ even if harsh conditions were needed to convert the phenol tautomer to the diketone in the case of the naphthohydroquinone. All C–C bond lengths in 1,4-hydroquinone (one aromatic ring) are almost identical. In contrast, the bond lengths in all other 1,4-hydroxy tautomers show alternating values for the bond lengths in the terminal aromatic rings (see ESI†). Furthermore, the diketone tautomers might allow a greater flexibility of the terminal ring, which can then better adapt to the constraints induced by the helical structure

Scheme 5 Demethylation of compound **11** (1,4-dimethoxy-[4] helicene).

Table 1 Energy differences corresponding to the conversion of the 1,4-dihydroquinone to the diketone tautomer in dichloromethane or in the gas phase for $[n]$ helicenes

Number of fused aromatic cycles $[n]$	1	2	3	4	5	6	7
ΔG (kcal mol ⁻¹)							
Dichloromethane	+6.4	-6.7	-5.0	-4.0	-3.4	-4.0	-3.9
Gas phase	+6.6	-6.3	-5.0	-2.2	-1.7	-3.2	-3.6

(see ESI† for the calculated dihedral angles). Both electronic and geometric effects seem to favor the diketone tautomers for all polyaromatics of this series up to the [6]helicene. From the results of the F. Diederich group, it was clear that 1,2-dihydroxy forms are the stable tautomers for [6]helicenes and this study demonstrated that the 1,4-diones were the stable tautomers for [6]helicenes. Calculations to determine the difference in energy between the tautomers with all possible hydroquinone isomers of [6]helicenes were performed and corroborated these experimental results. Fig. 4 represents the values of ΔG to undergo the transformations from the dihydroxy forms to the dione tautomers (*ortho*, *meta* and *para* structures).

For the three *ortho* isomers, the stable tautomers are the dihydroxy or catechols derivatives ($\Delta G = 6.6$, 4.9, and 4.9 kcal mol⁻¹). In the case of the *para* isomer, the stable

tautomer is clearly the dione ($\Delta G = -4$ kcal mol⁻¹). These results are in good agreement with the values obtained earlier for the stable tautomers of naphthohydroquinones (see ESI, Fig. S45†). For the *meta*-naphthohydroquinone, the dione is the stable tautomer (see ESI†), but for the two possible *meta* isomers of [6]helicenes, the results were different. In the case of the 1,3-*meta* isomer the dione is the stable tautomer ($\Delta G = -2$ kcal mol⁻¹), whereas for the 2,4-*meta* isomer the dihydroxy tautomer seems to be favored ($\Delta G = 0.8$ kcal mol⁻¹).

In an attempt to understand the origin of the different stability of the tautomers, Electron Localisation Function (ELF) analysis¹⁷ was performed on the reference benzene and naphthalene rings as well as on compounds **8** and **9** (Scheme 4). The aromaticity of naphthalene is smaller than that of benzene¹⁸ as can be seen on the ELF function (see ESI, Table S2†); the C-C ELF basin are identical in benzene whereas they are closer to an alternation of single and double bond in naphthalene. The ELF C-C basins in the naphthohydroquinone **8** are very close to that of naphthalene: the binding scheme is essentially the same. On the contrary in the dione **9**, the population of the ELF C-C basins of the remaining aromatic ring is very similar to that of benzene. We can then propose an hypothesis for the difference in the diol/dione equilibrium which is a balance between aromaticity, internal H-bond and geometry distortion induced by the presence of the C-C single bond in the dione form. For the *para* structures **8-9** and **3-4**, the equilibrium is displaced towards the dione form as the loss of the aromaticity of the terminal cycle is compensated by the reinforcement of the aromaticity of the other rings and furthermore the carbonyl function are also conjugated with the π -system. On the contrary, for the *ortho* structures, the equilibrium is displaced towards the diol form because the loss of the internal H-bond existing between the two O-H group is not compensated by the greater aromaticity of the dione form. In the *meta* structures, only one carbonyl group is conjugated with the π -system and the dione form is less stable than in the *para* isomer, furthermore the out-of-plane distortion due to the presence of the C-C single bond may further disfavour the dione form. This explains the smaller equilibrium displacement for the *meta* structures.

Experimental

Materials and methods

Commercially available reagent grade materials such as 2-naphthaldehyde and 2,6-dimethoxy-4-bromobenzaldehyde were used as obtained. The synthesis of 2-bromo-benzo[*c*]phenanthrene as well as its subsequent functionalisation were carried out following methodology described in the literature^{12,13} except for the photocyclisation steps which were adapted and are described below. THF was distilled from sodium/benzophenone ketyl. Column chromatography was performed with silica gel from Merck (Kieselgel 60; 63–200 μ m or 40–63 μ m). ¹H NMR spectra were recorded on Bruker Avance 400 (400 MHz) or 500 (500 MHz) spectrometers. Chemical shifts are given in parts per million (ppm) by taking the solvent as a reference $\delta_{\text{CHCl}_3} = 7.26$ ppm for ¹H NMR and $\delta_{\text{CHCl}_3} =$

Fig. 4 Energy differences to obtain the dione isomers from the dihydroxy tautomers (values in kcal mol⁻¹).

77.16 ppm for ^{13}C NMR. The coupling constants (J) are given in Hertz (Hz) and the multiplicity of the signals are expressed as: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet. Mass spectrometry (MS and HRMS) experiments were performed on a Bruker Daltonics microTOF spectrometer (Bruker Daltonik GmbH, Bremen, Germany) by the Service de Spectrométrie de Masse de la Fédération de Chimie "Le Bel" (FR 2010). Irradiation of stilbene derivatives was carried out with a Heraeus TQ 150 mercury vapor lamp in a 400 mL photo-reactor. The protons of ^1H spectra were assigned according to Martin's proposed nomenclature.^{1a}

Synthetic procedures

2-(2,5-Dimethoxystyryl)benzo[*c*]phenanthrene. Under argon, NaH (60% in mineral oil) (277 mg, 6.92 mmol, 1.32 eq.) was added to a solution of diethyl 2,5-dimethoxybenzylphosphonate (1.96 g, 6.81 mmol, 1.30 eq.) in freshly distilled THF (50 mL). After 15 min of stirring at room temperature, a solution of benzo[*c*]phenanthrene-2-carbaldehyde (1.34 g, 5.24 mmol, 1 eq.) in freshly distilled THF (30 mL) was added dropwise. The resulting solution was heated at 50 °C for 16 h. After the solution was allowed to cool to room temperature, H_2O (50 mL) was added. The THF was removed under reduced pressure. The solid was dissolved in CH_2Cl_2 (50 mL) and the resulting solution was washed with a saturated aqueous solution of NH_4Cl (3×20 mL), dried over MgSO_4 , and filtered. Subsequent purification of the crude product by column chromatography (SiO_2 , $\text{CH}_2\text{Cl}_2/\text{cyclohexane}$ 30/70) afforded the desired product as a yellow solid (1.91 mg, 4.89 mmol, 93%). ^1H NMR (CDCl_3 , 500 MHz, 25 °C): δ_{H} (ppm) = 9.18 (d, $J = 8.5$ Hz, 1H, H_{12}), 9.15 (s, 1H, H_1), 8.04 (dd, $J = 8.0$, 1.4 Hz, 1H, H_9), 8.00 (d, $J = 8.4$ Hz, 1H, H_4), 7.95 (dd, $J = 8.4$, 1.6 Hz, 1H, H_3), 7.91 (d, $J = 8.5$ Hz, 1H, H_{5-8}), 7.88 (d, $J = 8.5$ Hz, 1H, H_{5-8}), 7.82 (m, 2H, 2^*H_{5-8}), 7.74 (ddd, $J = 8.4$, 6.8, 1.5 Hz, 1H, H_{11}), 7.68 (d, $J = 16.4$ Hz, 1H, H_a), 7.66 (ddd, $J = 8.0$, 6.9, 1.1 Hz, 1H, H_{10}), 7.39 (d, $J = 16.4$ Hz, 1H, H_b), 7.27 (d, $J = 2.9$ Hz, 1H, $\text{H}_{\text{Ar-O}}$), 6.88 (d, $J = 8.9$ Hz, 1H, $\text{H}_{\text{Ar-m}}$), 6.84 (dd, $J = 8.9$, 2.9 Hz, 1H, $\text{H}_{\text{Ar-p}}$), 3.90 (s, 3H, OCH_{3-m}), 3.87 (s, 3H, OCH_{3-o}). ^{13}C NMR (126 MHz, CDCl_3): δ_{C} (ppm) = 153.9, 151.6, 135.8, 133.7, 133.1, 131.4, 130.8, 130.5, 130.0 (CH), 129.0 (CH), 128.7 (CH), 128.0 (CH), 127.7 (CH), 127.5, 127.4 (CH), 127.3 (CH), 127.3, 127.0 (CH), 126.9 (CH), 126.4, 126.0 (CH), 123.9 (CH), 123.5 (CH), 114.0 (CH), 112.5 (CH), 111.7 (CH), 56.5 (CH_3), 56.0 (CH_3). ESI-TOF-HR-MS (m/z): calcd for $[\text{M}^+]$ 390.1614; found 390.1633.

2-Bromo-1,4-dimethoxyhexahelicene (\pm) (compound 1). A solution of 2-(4-bromo-2,5-dimethoxystyryl)benzo[*c*]phenanthrene (1.12 g, 2.56 mmol, 1 eq.) and iodine (90 mg, 0.38 mmol, 15 mol%) in cyclohexane (400 mL) was irradiated in a photoreactor equipped with an immersion lamp (150 W) for 10 h. Sodium thiosulfate (5 g) was added and the solution was stirred overnight. The solvent was evaporated and the crude product was purified by column chromatography (SiO_2 , $\text{CH}_2\text{Cl}_2/\text{cyclohexane}$ 40/60) to afford compound 1 as a yellow solid (580 mg, 1.24 mmol, 52%). ^1H NMR (CDCl_3 , 500 MHz, 25 °C): δ_{H} (ppm) = 8.39 (d, $J = 8.7$ Hz, 1H, H_5), 8.10–7.87 (7d, 7H, $\text{H}_6 + \text{H}_7 +$

$\text{H}_8 + \text{H}_9 + \text{H}_{10} + \text{H}_{11} + \text{H}_{12}$) 7.81 (dd, $J = 8.0$, 1.4 Hz, 1H, H_{13}), 7.28–7.20 (m, 1H, H_{14}), 7.07 (dd, $J = 8.5$, 1.1 Hz, 1H, H_{16}), 6.87 (s, 1H, H_3), 6.60 (ddd, $J = 8.5$, 6.8, 1.4 Hz, 1H, H_{15}), 4.02 (s, 3H, $\text{OCH}_{3\text{out}}$), 2.08 (s, 3H, $\text{OCH}_{3\text{in}}$). ^{13}C NMR (126 MHz, CDCl_3): δ_{C} (ppm) = 151.9, 147.8, 132.6, 132.2, 132.2, 130.8, 129.1, 129.1, 128.1 (CH), 127.9 (CH), 127.5 (CH), 127.4 (CH), 126.3 (CH), 126.2 (CH), 126.1 (CH), 125.9 (CH), 125.6, 125.3 (CH), 125.3 (CH), 124.7, 124.1, 123.7, 123.3, 121.4 (CH), 114.4, 109.9 (CH), 58.4 (CH_3), 56.4 (CH_3). ESI-TOF-HR-MS (m/z): calcd for $[\text{M} + \text{Na}^+]$ 489.0461; found 489.0465.

1,4-Dimethoxyhexahelicene (\pm) (compound 2). A solution of 2-(2,5-dimethoxystyryl)benzo[*c*]phenanthrene (1.0 g, 2.56 mmol, 1 eq.) and iodine (49 mg, 0.38 mmol, 15 mol%) in cyclohexane (400 mL) was irradiated in a photoreactor equipped with an immersion lamp (150 W) for 10 h. Sodium thiosulfate (5 g) was added and the solution was stirred overnight. The solvent was evaporated and the crude product was purified by column chromatography (SiO_2 , $\text{CH}_2\text{Cl}_2/\text{cyclohexane}$ 40/60) to afford compound 2 as a yellow solid (337 mg, 0.87 mmol, 34%). Alternatively, compound 2 was also isolated as a side product of the synthesis of compound 1. ^1H NMR (CDCl_3 , 500 MHz, 25 °C): δ_{H} (ppm) = 8.43 (d, $J = 8.7$ Hz, 1H, H_5), 8.05 (d, $J = 8.1$ Hz, 1H, H_{7-12}), 8.02–7.95 (m, 4H, $\text{H}_6 + 3^*\text{H}_{7-12}$), 7.93 (d, $J = 8.5$ Hz, 1H, H_{7-12}), 7.85 (d, $J = 8.5$ Hz, 1H, H_{7-12}), 7.80–7.76 (m, 1H, H_{13}), 7.15 (ddd, $J = 7.9$, 6.8, 1.2 Hz, 1H, H_{14}), 7.11 (d, $J = 8.5$ Hz, 1H, H_{16}), 6.68 (d, $J = 8.5$ Hz, 1H, H_{2-3}), 6.58 (ddd, $J = 8.4$, 6.8, 1.4 Hz, 1H, H_{15}), 6.02 (d, $J = 8.5$ Hz, 1H, H_{2-3}), 4.02 (s, 3H, $\text{OCH}_{3\text{out}}$), 2.53 (s, 3H, $\text{OCH}_{3\text{in}}$). ^{13}C NMR (126 MHz, CDCl_3): δ_{C} (ppm) = 149.6, 132.2, 132.0, 131.8, 130.9, 128.9, 128.6, 127.3 (CH), 127.0 (CH), 127.0 (CH), 126.8 (CH), 126.6 (CH), 126.4 (CH), 126.4 (CH), 126.1 (CH), 125.7, 125.1 (CH), 124.6, 124.2, 123.6 (CH), 122.9, 121.2 (CH), 105.8 (CH), 104.8 (CH), 56.4 (CH_3), 53.8 (CH_3). ESI-TOF-HR-MS (m/z): calcd for $[\text{M}^+]$ 388.1458; found 388.1448.

Compounds 4, 5, and 6

With ethanol stabilised dichloromethane. Under argon, 4 mL of BBr_3 (1 M in CH_2Cl_2) were added to the solid 1,4-dimethoxyhexahelicene (160 mg, 0.41 mmol, 1 eq.) and the resulting solution was stirred at room temperature for 1 h. The solution was poured in 50 mL of water. The organic layer was washed with a saturated aqueous solution of NH_4Cl (2×20 mL), dried over MgSO_4 and filtered. Column chromatography (SiO_2 , $\text{CH}_2\text{Cl}_2(\text{EtOH stabilised})/\text{cyclohexane}$ 40/60) allowed to isolate 4 ($m = 68$ mg, 0.42 mmol, 43%), 5 (33 mg, 0.09 mmol, 22%) and 6 (51 mg, 0.14 mmol, 34%).

With freshly distilled dichloromethane. Under argon, 4 mL of BBr_3 (1 M in CH_2Cl_2) were added to the solid 1,4-dimethoxyhexahelicene (160 mg, 0.41 mmol, 1 eq.) and the resulting solution was stirred at room temperature for 1 h. The solution was poured in 50 mL of water. The organic layer was washed with a saturated aqueous solution of NH_4Cl (2×20 mL), dried over MgSO_4 and filtered. Column chromatography (SiO_2 , $\text{CH}_2\text{Cl}_2(\text{distilled})/\text{cyclohexane}$ 40/60) allowed to isolate 5 (77 mg, 0.21 mmol, 51%) and 6 (71 mg, 0.20 mmol, 48%). Compound 4: ^1H NMR (CDCl_3 , 500 MHz, 25 °C): δ_{H} (ppm) = 8.14 (d, $J = 8.3$ Hz, 1H, H_5), 8.11 (d, $J = 8.3$ Hz, 1H, H_6), 8.08 (d, $J = 8.4$ Hz, 1H, H_{13}),

8.05 (d, $J = 8.3$ Hz, 1H, H₇₋₁₂), 7.99–7.93 (m, 2H, H₇₋₁₂ + H₁₆), 7.91 (m, 2H, 2*H₇₋₁₂), 7.87 (bs, 2H, 2*H₇₋₁₂), 7.47 (ddd, $J = 8.0$, 7.0, 1.2 Hz, 1H, H₁₅), 7.29–7.19 (m, 1H, H₁₄), 2.95 (ddd, $J = 16.8$, 8.0, 4.8 Hz, 1H, H₂₋₃), 2.69 (ddd, $J = 16.6$, 9.6, 6.7 Hz, 1H, H₂₋₃), 2.06 (ddd, $J = 14.8$, 6.7, 4.8 Hz, 1H, H₂₋₃), 1.78 (ddd, $J = 14.8$, 9.6, 8.0 Hz, 1H, H₂₋₃). ¹³C NMR (126 MHz, CDCl₃): δ_C (ppm) = 196.7, 195.9, 139.2, 135.9, 133.5, 133.0, 133.0, 132.6 (CH), 131.1, 130.3 (CH), 130.1, 129.9, 129.1 (CH), 129.0 (CH), 127.9 (CH), 127.9 (CH), 126.8 (CH), 126.6 (CH), 126.4 (CH), 126.2 (CH), 125.4 (CH), 125.2, 123.5 (CH), 38.3 (CH₂), 35.8 (CH₂). ESI-TOF-HR-MS (m/z): calcd for ([M + K]⁺) 399.0782; found 399.0793. Compound 5: ¹H NMR (CDCl₃, 500 MHz, 25 °C): δ_H (ppm) = 8.51 (d, $J = 8.6$ Hz, 1H, H₅₋₁₂), 8.16–8.05 (m, 3H, 3*H₅₋₁₂), 8.03 (d, $J = 8.1$ Hz, 1H, H₅₋₁₂), 7.96 (bs, 2H, 2*H₅₋₁₂), 7.94 (d, $J = 8.6$ Hz, 1H, H₅₋₁₂), 7.83 (dd, $J = 7.9$, 1.5 Hz, 1H, H₁₃), 7.21 (ddd, $J = 8.0$, 7.0, 1.3 Hz, 1H, H₁₄), 7.03 (d, $J = 8.6$ Hz, 1H, H₂₋₃), 6.71 (d, $J = 8.4$ Hz, 1H, H₁₆), 6.63 (ddd, $J = 8.5$, 6.9, 1.5 Hz, 1H, H₁₅), 6.20 (d, $J = 8.4$ Hz, 1H, H₂₋₃), 4.28 (dq, $J = 8.5$, 6.9 Hz, 1H, CH₂), 4.13 (dq, $J = 8.7$, 6.9 Hz, 1H, CH₂), 3.86 (s, 1H, OH), 1.59 (t, $J = 6.9$ Hz, 3H, CH₃). ¹³C NMR (126 MHz, CDCl₃): δ_C (ppm) = 148.9, 146.1, 132.5, 132.4, 132.0, 130.6, 128.7 (CH), 128.5, 127.5 (CH), 127.5 (CH), 127.3 (CH), 127.2 (CH), 127.2 (CH), 126.5 (CH), 126.2 (CH), 125.7 (CH), 125.6 (CH), 124.4, 123.9 (CH), 123.4, 123.0, 122.4 (CH), 121.6, 111.8 (CH), 108.7 (CH), 65.1 (CH₂), 15.2 (CH₃). Compound 6: ¹H NMR (CDCl₃, 500 MHz, 25 °C): δ_H (ppm) = 8.22 (d, $J = 8.2$ Hz, 1H, H₅), 8.19 (d, $J = 8.2$ Hz, 1H, H₆), 8.14 (d, $J = 8.4$ Hz, 1H, H₁₃), 8.04–7.83 (6d + m, 7H, 6*H₇₋₁₂ + H₁₆), 7.40 (ddd, $J = 7.9$, 6.8, 1.2 Hz, 1H, H₁₅), 7.14 (ddd, $J = 8.4$, 6.9, 1.4 Hz, 1H, H₁₄), 6.54 (d, $J = 10.1$ Hz, 1H, H₂), 6.00 (d, $J = 10.1$ Hz, 1H, H₃). ¹³C NMR (126 MHz, CDCl₃): δ_C (ppm) = 185.6, 185.2, 140.0 (CH), 135.9, 134.9 (CH), 134.4, 133.6, 133.0 (CH), 132.5, 131.3, 130.5 (CH), 130.0, 129.7, 129.4 (CH), 128.9 (CH), 127.9 (CH), 126.8 (CH), 126.6 (CH), 126.4 (CH), 126.4 (CH), 126.3 (CH), 126.2 (CH), 126.1, 125.2, 123.0 (CH). ESI-TOF-HR-MS (m/z): calcd for ([M + H]⁺) 359.1067; found 359.1063.

2-(2,5-Dimethoxystyryl)naphthalene. Under argon, NaH (60% in mineral oil) (277 mg, 6.92 mmol, 1.32 eq.) was added to a solution of diethyl 2,5-dimethoxybenzylphosphonate (2.47 g, 9.0 mmol, 1.3 eq.) in freshly distilled THF (50 mL). After 15 min of stirring at room temperature, a solution of 2-naphthaldehyde (1.34 g, 8.6 mmol, 1.0 eq.) in 30 mL of distilled THF (30 mL) was added dropwise and the resulting solution was heated at 50 °C for 16 h. After the solution was allowed to cool to room temperature, H₂O (50 mL) was added. The THF was removed under reduced pressure. The solid was dissolved in CH₂Cl₂ (50 mL) and the resulting solution was washed with NH₄Cl_(sat.) (3 × 20 mL), dried over MgSO₄, and filtered. Subsequent purification of the crude solid by column chromatography (SiO₂, CH₂Cl₂/cyclohexane 40/60) afforded the desired product as a yellow solid (2.08 g, 7.1 mmol, 83%). ¹H NMR (CDCl₃, 500 MHz, 25 °C): δ_H (ppm) = 7.91–7.80 (m, 5H, H₁ + H₃ + H₄ + H₅ + H₈), 7.62 (d, $J = 16.4$ Hz, 1H, H_{alkene}), 7.47 (m, 2H, H₆ + H₇), 7.29 (d, $J = 16.4$ Hz, 1H, H_{alkene}), 7.24 (d, $J = 2.9$ Hz, 1H, H₉), 6.92–6.72 (m, 2H, H_m + H_p), 3.89 (s, 3H, OCH₃), 3.86 (s, 3H, OCH₃). ¹³C NMR (126 MHz, CDCl₃): δ_C (ppm) = 153.9, 151.6, 135.4, 133.8, 133.1, 129.5 (CH), 128.3 (CH), 128.1 (CH), 127.8 (CH), 127.3, 126.8 (CH), 126.4 (CH), 125.9, 123.8 (CH), 123.7 (CH), 113.9 (CH),

112.4 (CH), 111.6 (CH), 56.4 (CH₃), 55.9 (CH₃). ESI-TOF-HR-MS (m/z): calcd for ([M]⁺) 290.1301; found 290.1301.

1,4-Dimethoxybenzo[*c*]phenanthrene (compound 11). A solution of 2-(2,5-dimethoxystyryl)naphthalene (1.0 g, 3.44 mmol, 1 eq.) and iodine (49 mg, 0.38 mmol, 15 mol%) in cyclohexane (400 mL) was irradiated in a photoreactor equipped with an immersion lamp (150 W) for 10 h. Sodium thiosulfate (5 g) was added and the solution was stirred overnight. The solvent was evaporated and the crude product was purified by column chromatography (SiO₂, CH₂Cl₂/cyclohexane 40/60) to afford compound 11 as a yellow solid (492 mg, 1.72 mmol, 49%). ¹H NMR (CDCl₃, 500 MHz, 25 °C): δ_H (ppm) = 8.35 (d, $J = 8.7$ Hz, 1H, H₅), 8.14 (dd, $J = 8.4$, 1.3 Hz, 1H, H₁₂), 7.98–7.89 (m, 2H, H₈ + H₉), 7.82 (d, $J = 8.5$ Hz, 1H, H₇), 7.81 (d, $J = 8.7$ Hz, 1H, H₆), 7.55 (ddd, $J = 8.0$, 6.8, 1.4 Hz, 1H, H₁₀), 7.51 (ddd, $J = 8.3$, 6.8, 1.6 Hz, 1H, H₁₁), 7.07 (d, $J = 8.6$ Hz, 1H, H₂), 7.02 (d, $J = 8.5$ Hz, 1H, H₃), 4.06 (s, 3H, OCH_{3out}), 3.76 (s, 3H, OCH_{3in}). ¹³C NMR (126 MHz, CDCl₃): δ_C (ppm) = 150.8, 150.2, 132.5, 131.9, 131.3 (CH), 130.3, 127.9 (CH), 127.1 (CH), 126.6 (CH), 126.4, 125.9 (CH), 125.8, 125.5 (CH), 123.5 (CH), 121.2, 120.9 (CH), 107.6 (CH), 105.7 (CH), 56.3 (CH₃), 55.1 (CH₃). ESI-TOF-HR-MS (m/z): calcd for ([M + H]⁺) 288.1145; found 288.1151.

Benzo[*c*]phenanthrene-1,4-dione (compound 14) and 2,3-dihydrobenzo[*c*]phenanthrene-1,4-dione (compound 12). Under argon, 10 mL of BBr₃ (1 M in CH₂Cl₂) were added to the solid 1,4-dimethoxybenzo[*c*]phenanthrene (11) (400 mg, 1.39 mmol, 1 eq.) and the resulting solution was stirred at room temperature for 1 h. The solution was poured in 50 mL of water. The organic layer was washed with a saturated aqueous solution of NH₄Cl (2 × 30 mL), dried over MgSO₄ and the solvents were removed under reduced pressure. Column chromatography (SiO₂, CH₂Cl₂(distilled)/cyclohexane 40/60) allowed to isolate compound 12 (189 mg, 0.72 mmol, 52%) and compound 14 (170 mg, 0.66 mmol, 47%). Compound 14: ¹H NMR (CDCl₃, 500 MHz, 25 °C): δ_H (ppm) = 8.34 (d, $J = 8.3$ Hz, 1H, H₁₂), 8.21 (d, $J = 8.1$ Hz, 1H, H₅), 8.07 (d, $J = 8.2$ Hz, 1H, H₆), 7.91–7.85 (m, 2H, H_{7/8} + H₉), 7.68 (d, $J = 8.7$ Hz, 1H, H_{7/8}), 7.62 (ddd, $J = 8.0$, 7.0, 1.2 Hz, 1H, H₁₀), 7.48 (ddd, $J = 8.5$, 6.9, 1.4 Hz, 1H, H₁₁), 7.14 (d, $J = 10.2$ Hz, 1H, H₂), 6.98 (d, $J = 10.2$ Hz, 1H, H₃). ¹³C NMR (126 MHz, CDCl₃): δ_C (ppm) = 188.5, 185.3, 140.3 (CH), 136.9, 136.2 (CH), 134.0, 133.8 (CH), 132.9, 132.7, 131.2 (CH), 130.0 (CH), 129.4, 129.2, 128.3 (CH), 128.3 (CH), 125.9 (CH), 125.4 (CH), 123.3 (CH). ESI-TOF-HR-MS (m/z): calcd for ([M + H]⁺) 259.0754; found 259.0751. Compound 12: due to fast oxidation of the compound to the corresponding quinone, signals of the quinone were always found in the NMR data of the reduced form. ¹H NMR (CDCl₃, 500 MHz, 25 °C): δ_H (ppm) = 8.17 (m, 2H, H₅ + H₁₂), 8.04 (d, $J = 8.3$ Hz, 1H, H₆), 7.95–7.85 (m, 2H, H_{7/8} + H₉), 7.71 (d, $J = 8.7$ Hz, 1H, H_{7/8}), 7.62 (ddd, $J = 8.5$, 6.9, 1.5 Hz, 1H, H₁₀), 7.52 (ddd, $J = 8.5$, 6.9, 1.5 Hz, 1H, H₁₁), 3.52 (t, $J = 7.2$ Hz, 2H, H₂), 3.31 (t, $J = 7.2$ Hz, 2H, H₃). ¹³C NMR (126 MHz, CDCl₃): δ_C (ppm) = 202.1, 195.1, 138.4, 137.1, 135.6, 133.8, 133.1 (CH), 131.4 (CH), 129.0 (CH), 129.0, 128.9 (CH), 128.0, 127.9 (CH), 126.1 (CH), 126.1 (CH), 123.8 (CH), 40.1 (CH₂), 39.3 (CH₂). ESI-TOF-HR-MS (m/z): calcd for ([M + H]⁺) 261.0910; found 261.0921.

Computational details

All calculations were done with GAUSSIAN 09 (version D01) at DFT level of theory (ω B97XD functional). All atoms were described by 6-31+G** basis set. Solvent corrections of dichloromethane were introduced through PCM model. Frequency calculations were done on the basis of optimised geometry within harmonic approximation. Gibbs free energies were extracted from this frequency analysis. The tautomerism equilibrium were computed from the reaction: $\Delta G = G(\text{diketo}) - G(\text{diol})$. Topological analyses were performed on the optimized structure wavefunction using the TOPMOD package.¹⁹

Crystallography

A specimen of $\text{C}_{28}\text{H}_{19}\text{BrO}_2$, approximate dimensions 0.150 mm \times 0.200 mm \times 0.200 mm, was used for the X-ray crystallographic analysis. The X-ray intensity data were measured ($\lambda = 0.71073$ Å). The integration of the data using a monoclinic unit cell yielded a total of 91 304 reflections to a maximum θ angle of 27.92° (0.76 Å resolution), of which 9892 were independent (average redundancy 9.230, completeness = 99.9%, $R_{\text{int}} = 4.68\%$, $R_{\text{sig}} = 2.15\%$) and 8445 (85.37%) were greater than $2\sigma(F^2)$. The final cell constants of $a = 14.6897(5)$ Å, $b = 14.0457(6)$ Å, $c = 20.6528(7)$ Å, $\beta = 104.4410(10)^\circ$, volume = 4126.6(3) Å³, are based upon the refinement of the XYZ-centroids of reflections above $20\sigma(I)$. The calculated minimum and maximum transmission coefficients (based on crystal size) are 0.6577 and 0.7456. The structure was solved and refined using the Bruker SHELXTL Software Package, using the space group $P2_1/c$ (14), with $Z = 8$ for the formula unit, $\text{C}_{28}\text{H}_{19}\text{BrO}_2$. The final anisotropic full-matrix least-squares refinement on F^2 with 563 variables converged at $R_1 = 2.95\%$, for the observed data and $wR_2 = 7.64\%$ for all data. The goodness-of-fit was 1.006. The largest peak in the final difference electron density synthesis was $0.749 \text{ e}^- \text{ \AA}^{-3}$ and the largest hole was $-0.733 \text{ e}^- \text{ \AA}^{-3}$ with an RMS deviation of $0.061 \text{ e}^- \text{ \AA}^{-3}$. On the basis of the final model, the calculated density was 1.504 g cm^{-3} and $F(000)$, 1904 e^- . CCDC no. 2092869.†

Conclusions

In conclusion, the well-known redox system quinone–hydroquinone led to unexpected results for the parent [4]helicene and [6]helicene “hydroquinones”. The 1,4-hydroquinone (or phenolic form) which was expected and which is indeed present after reduction of benzoquinone or 1,4-naphthoquinone, was not observed after demethylation of the 1,4-dimethoxy derivatives of slightly larger π -conjugated fused aromatics. These experimental results were then corroborated by DFT calculations, which clearly indicated that the diketone tautomers were the more stable forms for larger fused aromatic “hydroquinones”.

Conflicts of interest

There are no conflicts to declare.

Acknowledgements

VS thanks the French Ministry of Research for his PhD fellowship. We thank the HPC computer center of the University of Strasbourg for the computation facilities. We thank Nathalie Gruber for solving the structure, Marion Jean and Nicolas Vanthuyne (Chiropole, Aix-Marseille University) for chiral HPLC separations.
