Stereoselective Shi-type epoxidation with 3-oxo-4,6-O-benzylidene pyranoside catalysts: unveiling the role of carbohydrate skeletons†

Daniela Imperio, ^a Filippo Valloni, ^a Diego Caprioglio, ^a Alberto Minassi, ^a Emanuele Casali ^b and Luigi Panza ^a

Asymmetric epoxidation represents a hot topic in organic synthesis. In recent years, organocatalysts based on sugar skeletons have been exploited in asymmetric epoxidation to achieve enantiomeric pure epoxides. In this work, two different endocyclic ketones derived from glucose and galactose protected with a 4,6-O-benzylidene group have been prepared and exploited for Shi-type epoxidation. The two carbohydrates show an opposite preferential stereoselective epoxidation on various olefins, affording the epoxides in high conversions and modest enantioselectivities. DFT calculations disclosed the reasons behind the inversion of selectivity achieved by the two catalysts, showing that a delicate balance between the catalyst conformation, its protecting groups, and the secondary interactions with the substrate govern the final observed results.

Introduction

Organocatalysis has started to be one of the most valuable fields of organic synthesis to help green chemistry.^{1,2} The increasing demand for scaffolds in the development of new organocatalysts has spurred researchers to explore carbohydrates with distinctive characteristics, making them promising candidates for organocatalysis.^{3,4} In the last years, several ketones based on sugar skeletons have been developed to be exploited in Shi-type epoxidation. In 1996, Shi *et al.* reported the use of a fructose-derived ketone as an organocatalyst for enantioselective epoxidation of *trans*-olefins with potassium peroxyomonosulfate (Oxone) as oxidant.^{5,6} Since then, several other ketones have been prepared to achieve better selectivity and yields.^{7–11} Small ring heterocycles, such as epoxides, are present in several natural compounds^{12,13} and represent highly versatile building blocks, frequently involved in the synthesis of pharmaceuticals and bioactive products.^{14–16} In addition, carbohydrates possess several hydroxyl groups, which is a unique and valuable characteristic to serve as binding sites, being easily converted to other functional groups based on the structural requirements for catalyst development. In addition, the attachment of bulky groups to these hydroxyl moieties can also be used to block the space around the reactive site of the catalyst, which can control

Fig. 1 Structures of the two catalysts for asymmetric epoxidation.

and direct the stereochemistry of the reaction. Moreover, the presence of free electron pairs on the endocyclic oxygen also provides an additional binding site and aids in the regulation of the selectivity of the reaction. Among bulky and rigid groups, benzylidene moiety has been largely exploited to modulate sugar reactivities for example to direct the stereoselectivity in glycosylation reactions.^{17–19} In the literature, keto derivatives of glucosamine²⁰ or mannose²¹ containing a benzylidene group showed interesting results in terms of epoxidation stereoselectivity. With the aim of expanding the orienting effect of benzylidene groups, two novel catalysts based on glucose and galactose skeletons (Fig. 1, catalysts 1 and 2 respectively) have been synthesized and tested on several olefins. To our delight, the change from *gluco* to *galacto* series allows a reversal of stereoselectivity in the epoxidation reaction.

Results and discussion

The synthesis of catalyst 1 was achieved in three reaction steps (Scheme 1). The commercial methyl α -D-glucopyranoside (Me α -D-glu) was reacted with benzaldehyde dimethyl acetal in

acetone in the presence of camphorsulfonic acid (CSA) to give the crude compound 3, which crystallized from ethanol after quenching with triethylamine and solvent removal. The white solid was selectively acetylated by using a modified procedure from the literature.²² The benzylidene derivative 3 was dissolved in vinyl acetate and Lipase PS was added. The reaction was warmed at 45 °C and gently stirred for 7 days. After the filtration of the enzyme and evaporation of the solvent, compound 4 was purified by chromatography. The final oxidation with *O*-iodoxybenzoic acid (IBX) in dry acetonitrile at 85 °C afforded catalyst 1 in almost quantitative yields. The synthesis of catalyst 2 was performed starting from *D*-galactose (*D*-gal), which was reacted with benzaldehyde dimethyl acetal in dry DMF in the presence of camphorsulfonic acid. The reaction was quenched with triethylamine, the solvent was evaporated, and the crude was purified by flash chromatography obtaining compound 5 in satisfactory yields. The derivate was then suspended in a mixture of dimethoxypropane/acetone with a catalytic amount of camphorsulfonic acid and stirred for 1 h at 60 °C. After quenching with triethylamine, it was purified by flash chromatography and the obtained compound 6 was oxidized to final ketone 2 in the presence of IBX in dry acetonitrile at 85 °C.

Having in hand the two catalysts, we performed the epoxidation of several olefins at 0 °C exploiting Oxone as oxidant and keeping the pH at ~10 by slowly adding an aqueous solution of K₂CO₃. The results are listed in Table 1. In all entries, excellent conversions and good yields were obtained with both of the two catalysts (80–100%). The epoxides were analyzed for the enantio- or diastereoselectivity by chiral HPLC (entries 1–5, 7–11) or by NMR (entries 6, 12). It is noteworthy that an inversion of epoxidation stereoselectivity was observed when employing the two catalysts, each possessing an opposite stereocenter at C4. Moreover, catalyst 2 resulted in better yield and stereoselectivity (see entries 4, and 10). Satisfactory results were also observed when the catalyst was used in 10% (entry 9b). When (*R*)-(+)-limonene was used as a substrate, a different outcome was

obtained. Catalyst 1 showed to be effective on 1,2 epoxidation (entry 6), preferring the *trans* product.²³ The two diastereomers cannot be separated by a chromatography column. Catalyst 2 performed better in terms of yields, by producing the four bis epoxide as an inseparable mixture (entry 12). Finally, considering the high conversions determined by ¹H-NMR, the modest yields could be derived from the intrinsic instability of the epoxides during the purification step even if neutral silica was used.²⁴

With the aim of providing an in-depth investigation on the reason governing the observed selectivity, extensive DFT calculations were performed (see ESI† for computational details). According to the results reported above, special attention was paid to the observed inversion in selectivity exerted by the two catalysts.

The main focus was thus applied to the interactions that regulate the observed selectivity on the epoxidation in response to the change in chirality on the C4 and protecting groups of the two sugar-based catalysts, using 9 as a model substrate.

The computational investigation started with the conformational analysis of all the possible transition states leading to the two enantiomeric products. Only the most stable for catalysts 1 and 2 will be reported and examined (Fig. 2; for a full analysis on the most stable structures for each catalyst, see the ESI file†).

Starting from the overall analysis of both the transition state structures obtained with catalysts 1 and 2, a change in the face of the olefin where the epoxidation occurs can be spotted. In particular, while catalyst 1 prefers approaching the substrate along the *Si*-face (1-TS-RR-a), 2 favors the epoxidation to occur on the *Re*-face (2-TS-SS-a). The distances of the bonds directly involved in the epoxidation step are similar in the two cases (cfr., 1.93 Å and 2.32 Å for catalyst 1, 2.02 Å and 2.36 Å for catalyst 2) and thus cannot be used as an explanation for the obtained results. However, a closer look at the surrounding region showed an important difference between the two cases. Indeed, with catalyst 1 a non-covalent H-bond interaction can occur between the styrene olefinic hydrogen H1 and the carbonylic oxygen O2b of the acetate protecting group on C2. This H-bond is established at a distance of 2.26 Å and directs the highly polarizable hydrogen in styrene position towards the electron-rich oxygen of the nearby protecting group.

With the modification of the catalyst structure in 2, thanks to the change in chirality on C4 of the galactose ring, all the system has to accommodate the *cis*-decalin conformation of the benzylidene protecting group. This results in a consistent and non-innocent increase in steric encumbrance on to the upper face of the galactose ring. However, even if this strong modification in steric occupancy plays an important role in determining the approaching trajectory of the incoming substrate, another consideration has to be taken regarding the modification in the protecting group on C2. Differently from catalyst 1, 2 shows an acetonide protection which binds together the hydroxyl groups on C1 and C2. The huge difference has not to be searched in the O2a-which was present and similarly oriented also in 1, but in the absence of O2b in 2. This removes any possible opportunity for the styrene hydrogen H1 to establish and orient towards the

carbonylic oxygen O2b, which was explicit in 1-but not present in 2. As a consequence of this structural modification, the styrene substrate prefers approaching the dioxirane moiety of 2 by facing the opposite side of the olefin (*i.e.*, *Re*-face). The reason for this change in the olefin face can be also explained by looking at the new possible interactions that can arise between the styrene H1 and the benzylidene protecting group. Indeed, being now oriented upwards, the benzylidene group can provide the oxygen O4 to establish a new H-bond interaction with H1. This non-covalent bond occurs at 2.40 Å, a higher distance

respect the one observed before, but it appears to be extremely favored by the intrinsic conformational shape of 2.

This infers that selectivity is probably impacted by the ability to establish secondary interactions with the hydrogen atoms on the olefin, along with alterations in the protecting groups and the initially assumed conformation of the catalyst. Consequently, the presence and arrangement of neighboring groups capable of engaging with the catalyst – considering the geometry assumed by the alkene in the substrate – govern the ultimate outcome.

Experimental

General

Reagents were purchased from Sigma-Aldrich, TCI, or Carlo Erba (Milan, Italy) and used without further purification. Thin-layer chromatography was performed on silica gel plates with fluorescent indicators. Visualization was accomplished by UV light (254 nm) and/or staining in ceric ammonium molybdate or sulfuric acid solution. Anhydrous solvents were obtained by utilizing activated molecular sieves (0.3 or 0.4 nm depending on the type of solvent). NMR spectra were recorded using a Bruker Avance Neo 400 MHz spectrometer (Bruker, Italy). Chemical shifts (δ) are quoted in parts per million referenced to the residual solvent peak. Melting points were determined using a Stuart Scientific SMP3 apparatus and remained uncorrected. Optical rotations were measured on a JASCO P1010 polarimeter at 20 °C. The instrument used for exact mass determination was an Orbitrap QExactive PLUS (Thermo Fischer Scientific, Bremen, Germany). Infrared Spectroscopy was performed using a Bruker Alpha II FTIR. The HPLC chromatograms were performed on a Shimadzu instrument equipped with a Lux® 5 μ m cellulose-2, LC column 250 \times 4.6 mm, at 25 °C with a photodiode array detector with an elution system of hexane : isopropanol at a flow rate of 0.5 mL min⁻¹, in an isocratic way. Retention times were compared to racemic mixtures previously synthesized.¹⁰

Synthetic procedures

4,6-O-benzylidene-methyl- α -D-glucopyranoside (3).²⁵ 5.0 g of methyl α -D-glucopyranoside (25.8 mmol) were dissolved in 75 mL of ACN, then 15 mL of benzaldehyde dimethyl acetal and 595 mg (2.5 mmol) of CSA were added. The mixture was stirred for 4 hours at rt. The reaction was neutralized with 0.6 mL of triethylamine and then the solvent evaporated. The compound was obtained as a white powder after crystallization from ethanol (5.0 g, yield 69%). ¹H NMR (400 MHz, CDCl₃) δ 7.52 (m, 2H), 7.44–7.37 (m, 3H), 5.55 (s, 1H), 4.82 (d, J = 3.9 Hz, 1H), 4.32

(dd, J = 9.6, 4.2 Hz, 1H), 3.95 (t_{app}, J = 9.2 Hz, 1H), 3.87–3.71 (m, 2H), 3.65 (dd, J = 9.2, 3.9 Hz, 1H), 3.52 (t_{app}, J = 9.2 Hz, 1H), 3.48 (s, 3H), 2.36 (bs, 2H).

Methyl 2-O-acetyl-4,6-O-benzylidene- α -D-glucopyranoside (4).²⁶ 1.0 g (3.6 mmol) of 3 was dissolved in 70 mL of vinyl acetate, 670 mg of Lipase PS was added, and gently stirred at 45 °C in an oil bath for 7 days. The suspension was filtered off, the solvent was evaporated, and the crude was purified by a chromatography column packed with flash silica using Cy/EtOAc 5 : 5 as eluents. 650 mg of a white powder was obtained (80% yield). ¹H NMR (400 MHz, CDCl₃) δ 7.52 (m, 2H), 7.40 (m, 3H), 5.58 (s, 1H), 4.99 (d, J = 3.6 Hz, 1H), 4.84 (dd, J = 9.7, 3.6 Hz, 1H), 4.33 (dd, J = 9.9, 4.5 Hz, 1H), 4.22 (t_{app}, J = 9.5 Hz, 1H), 3.98–3.72 (m, 2H), 3.60 (t, J = 9.3 Hz, 1H), 3.44 (s, 3H), 2.43 (bs, 1H), 2.19 (s, 3H).

Methyl 2-O-acetyl-4,6-O-benzylidene- α -D-ribo-pyran-3-uloside (1). 280 mg of 4 was dissolved in 9 mL of ACN, IBX (2.5 equiv.) was added, and the mixture was stirred at 80 °C for 8 hours. The suspension was filtered off a silica pad. The filtrate was evaporated and purified by flash chromatography using PE/EtOAc 5 : 5 as eluents. A white powder was obtained (93% yield). Mp 152–154 °C, $[\alpha]_D^{20}$: +60.6 (c = 1.0, CHCl₃) ¹H-NMR: (400 MHz, CDCl₃) δ 7.58–7.45 (m, 2H, Ar) 7.43–7.34 (m, 3H, Ar), 5.60 (s, 1H, CH-Benz), 5.41 (dd, J = 4.0, 1H, H-2), 5.25 (d, J = 4.1, 1H, H-1), 4.44 (dd, J = 10.3, 4.6, 1H, H6a), 4.39 (d, J = 9.8, 1H, H-4), 4.14 (td, J = 9.9, 9.8, 4.6, 1H, H-5), 3.97 (t, J = 10.2, 1H, H6b), 3.49 (s, 3H, CH₃-OMe) 2.25 (s, 3H, CH₃-OAc). ¹³C-NMR: (101 MHz, CDCl₃) δ 191.94 (CO), 169.66 (C OAc), 129.39 (C Ar), 128.32 (C Ar), 126.38 (C Ar), 101.99 (C Benz), 101.30 (C1), 82.14 (C4), 74.63 (C2), 69.37 (C6), 65.47 (C5), 55.66 (C OMe), 20.52 (C OAc). IR: 2940, 2914, 1751, 1740, 1235, 1122, 1051, 1014, 920, 752, 694, 462. HRMS (C₁₆H₁₈O₇): found 345.09416 m/z [M + Na]⁺ (vs. calcd 345.09502).

4,6-O-benzylidene-D-galactose (5).²⁷ 5.0 g (27.8 mmol) of commercial D-galactose was dissolved in 15 mL of dry DMF, 12.5 mL of benzaldehyde dimethyl acetal, and 644 mg of CSA

were added. The mixture was stirred for 3 hours. The mixture was quenched with 0.7 mL of triethylamine, the solvent was evaporated, diethyl ether and water were added (40 mL, 1 : 1) and the phases were separated. The aqueous layer containing the product was evaporated and the crude was purified with a chromatographic column packed with flash silica using EtOAc/MeOH 9 : 1 as eluents. A yellow oil was obtained (yield 51%). ^1H NMR (400 MHz, CD_3OD) δ 7.58–7.53 (m, 2H), 7.40–7.34 (m, 3H), 5.62 (s, 1H), 5.25 (d, J = 3.6 Hz, 1H), 4.27 (d, J = 3.6 Hz, 1H), 4.15 (m, 2H), 3.97 (m, 2H), 3.87 (dd, J = 10.1, 3.6 Hz, 1H).

4,6-O-benzylidene-1,2-O-isopropylidene- α -D-galactopyranoside (6).²⁸ Compound 5 (1.5 g, 5.86 mmol) was dissolved in 10 mL of dry acetone and 15 mL of dimethoxypropane, and 25 mg of CSA was added. The mixture was stirred for 1 hour at 60 °C. The reaction was neutralized with 0.6 mL of triethylamine and then the solvent evaporated. The compound was purified by flash chromatography using PE/EtOAc 5 : 5 as eluents (yield 42%). ^1H NMR (400 MHz, CDCl_3) δ 7.52–7.37 (m, 5H), 5.88 (d, J = 4.3 Hz, 1H), 5.59 (s, 1H), 4.40 (dd, J = 12.7, 1.1 Hz, 1H), 4.34 (dd, J = 4.3, 2.3 Hz, 1H), 4.22–4.17 (m, 1H), 4.14 (dd, J = 12.7, 2.3 Hz, 1H), 4.10–4.04 (m, 1H), 3.88 (d, J = 1.4 Hz, 1H), 2.72 (d, J = 7.6 Hz, 1H), 1.57 (s, 3H), 1.42 (s, 3H).

4,6-O-benzylidene-1,2-O-isopropylidene- α -D-xylo-pyran-3-ulose (2). 450 mg of 6 (1.46 mmol) were dissolved in 9 mL of dry ACN, IBX (2.5 equiv.) was added, and the mixture was stirred at 80 °C for 3 hours. The suspension was filtered off on a silica pad. The filtrate was evaporated and purified by flash chromatography using PE/EtOAc 5 : 5 as eluents. A waxy powder was obtained (72% yield). $[\alpha]_D^{20}$: -10.3 (c = 1.0, CHCl_3) ^1H NMR (400 MHz, CDCl_3) δ 7.52 (dd, J = 6.4, 2.8 Hz, 2H, Ar), 7.43–7.30 (m, 3H, Ar), 6.02 (d, J = 4.8 Hz, 1H, H-1), 5.63 (s, 1H, CH benz), 4.60 (d, J = 2.3 Hz, 1H, H-4), 4.54 (d, J = 4.8 Hz, 1H, H-2), 4.43 (dd, J = 12.9, 1.3 Hz, 1H, H-6a), 4.36 (m, 1H, H-5), 4.22 (dd, J = 12.9, 2.3 Hz, 1H, H-6b), 1.61 (s, 3H), 1.43 (s, 3H). ^{13}C NMR (101 MHz, CDCl_3) δ 198.14 (CO), 137.01 (C Ar), 129.32 (C Ar), 128.32 (C Ar), 100.46 (C Benz), 100.22 (C1), 76.75 (C4), 76.44 (C2), 68.86 (C6), 65.14 (C5), 26.38 (CH₃), 25.96 (CH₃). General procedure for epoxidation

In a jacketed flask cooled at 0 °C, the olefin (0.4 mmol) and the catalyst 1 or 2 (10–30 mol%) were dissolved in a mixture formed by ACN–dimethoxyethane (8 mL, 1 : 3). Tetrabutylammonium hydrogen sulfate (10 mg) was added followed by a buffer solution (4 mL) containing Na_2EDTA (4×10^{-4} M) and CH_3COOH – K_2CO_3 0.1 M (pH ~ 9). Two solutions respectively of Oxone (1.28 mmol) (2.5 mL) and an aqueous solution of K_2CO_3 1 M (2.5 mL) were simultaneously added dropwise over 6 hours and then stirred for 18 hours. The mixture was diluted with water (10 mL) and extracted with the appropriate organic solvent (hexane or DCM, entry 5). The organic fraction was dried over Na_2SO_4 and evaporated at 25 °C. Conversion was determined by ^1H NMR; enantioselectivity and the configuration of epoxides were

established by comparison with those reported in the literature by using chiral HPLC¹⁰ or NMR for entry 6, 12 in Table 1. The crude material was purified by flash chromatography on neutral silica (SiO_2 ·Et₃N 2.5%).²⁴

Products characterization

Styrene oxide (7a).²⁹ ^1H NMR (400 MHz, CDCl_3): δ 7.64–6.98 (m, 5H), 3.89 (dd, J = 4.1, 2.6 Hz, 1H), 3.18 (dd, J = 5.5, 4.1 Hz, 1H), 2.83 (dd, J = 5.5, 2.6 Hz, 1H). (95 : 5 hexane/2-propanol, 0.5 mL min⁻¹, monitor at 220 nm): 10.1 min (*R*) and 10.7 min (*S*).

cis- β -methylstyrene oxide (8a).³⁰ ^1H NMR (400 MHz, CDCl_3): δ 7.43–7.27 (m, 5H), 4.09 (d, J = 4.2 Hz, 1H), 3.37 (qd, J = 5.4, 4.2 Hz, 1H), 1.12 (d, J = 5.4 Hz, 3H). (90 : 10 hexane/2-propanol, 0.5 mL min⁻¹, monitor at 210 nm): 8.4 min (*R,S*) and 9.3 min (*S,R*).

trans- β -methylstyrene oxide (9a).³¹ ^1H NMR (400 MHz, CDCl_3): δ 7.46–7.22 (m, 5H), 3.60 (d, J = 2.0 Hz, 1H), 3.07 (qd, J = 5.1, 2.0 Hz, 1H), 1.48 (d, J = 5.1 Hz, 3H). (90 : 10 hexane/2-propanol, 0.5 mL min⁻¹, monitor at 220 nm): 8.6 min (*R,R*) and 10.2 min (*S,S*).

1-Phenylcyclohexene oxide (10a).³² ^1H NMR (400 MHz, CDCl_3): δ 7.45–7.23 (m, 5H), 3.16–3.02 (m, 1H), 2.36–2.26 (m, 1H), 2.15 (dt, J = 14.8, 5.2 Hz, 1H), 2.02 (ddt, J = 9.9, 5.2, 2.5 Hz, 2H), 1.69–1.44 (m, 3H), 1.35 (m, 1H). (95 : 5 hexane/2-propanol, 0.5 mL min⁻¹, monitor at 220 nm): 7.7 min (*R,R*) and 8.4 min (*S,S*).

Cinnamyl alcohol oxide (11a).²⁹ ^1H NMR (400 MHz, CDCl_3): 7.50–7.26 (m, 5H), 4.08 (dd, J = 12.7, 2.4 Hz, 1H), 3.96 (d, J = 2.1 Hz, 1H), 3.83 (dd, J = 12.7, 3.9 Hz, 1H), 3.25 (dt, J = 3.9, 2.4 Hz, 1H), 1.92–1.80 (bs, 1H). (80 : 20 hexane/2-propanol, 0.5 mL min⁻¹, monitor at 210 nm): 13.1 min (*R,R*) and 15.1 min (*S,S*).

1,2-Limonene oxide (mixture of 12a-b).²³ ^1H NMR (400 MHz, CDCl_3): δ 4.65 (m, 2H), 3.07 (m, 1H, 0.68H, *R,S*), 3.01 (d, J = 4.0 Hz, 0.32H, *S,R*), 2.15–2.00 (m, 2H), 1.86–1.75 (m, 2H), 1.70–1.61 (m, 4H), 1.53–1.47 (m, 1H), 1.26 (m, 3H), 1.25–1.14 (m, 1H).

^{13}C NMR (101 MHz, CDCl_3) δ 149.26 (12a), 149.05 (12 b), 109.09, 109.03, 60.56, 59.30, 57.53, 57.37, 40.76, 36.21, 30.76, 30.73, 29.88, 28.63, 25.92, 24.35, 24.29, 23.11, 21.10, 20.23.

1,2,8,9-Limonene dioxide (mixture of 12c-f).^{33,34} ^1H NMR (400 MHz, CDCl_3): δ 3.07–2.93 (m, 1H), 2.64–2.46 (m, 2H), 2.20–1.69 (m, 3H), 1.67–1.41 (m, 3H), 1.39–1.30 (m, 1H), 1.30 (s, 3H), 1.22 (s, 3H). ^{13}C NMR (101 MHz, CDCl_3) δ 60.46, 60.06, 58.76, 58.65, 57.37, 57.31, 53.35, 53.15, 52.94, 52.64, 39.98, 39.38, 35.38, 34.81, 30.29, 30.17, 29.71, 28.80, 28.47, 27.73, 26.67, 26.52, 24.37, 24.30, 23.60, 23.39, 23.01, 21.43, 21.32, 18.8 (C-10, 12d), 18.2 (C-10, 12e), 18.1 (C-10, 12c), 17.5 (C-10, 12f).

Conclusions

In summary, the synthesis of two organocatalysts based on the skeleton of glucose and galactose both oxidized at carbon-3 and protected as 4,6-benzylidene was achieved shortly, in good yields starting from renewable and low-cost materials. The two catalysts showed great efficiency in epoxidation reactions, almost always achieving complete conversion and good yields.

Although some stereoselectivities were modest, they demonstrated the ability to handle typically challenging terminal olefin substrates. (e.g., styrene, entry 1, 7). Furthermore, through DFT investigations, we discovered that by altering the protecting group on the C2 hydroxyl and reversing the C4 stereocenter, an important interaction could be eliminated, resulting in an opposite stereoselectivity in epoxidation and thus circumventing the need for the costlier enantiomer of the sugars.

Data availability

Data will be made available on request.

Author Contributions

Conceptualization: DI, LP; data curation: DI, EC; formal analysis: EC; investigation DI, EC, FV, DC; supervision: LP, AM; writing – original draft: DI, EC; writing – review & editing: all authors.

Conflicts of interest

The authors declare that "There are no conflicts to declare."

Acknowledgements

This work was supported by the Italian Ministry for University and Research (MUR, PRIN 2020, 2020AEX4TA project). The authors want to express their gratitude to Professor Lucio Toma, for the insightful discussions.
