Ni–Sr/TiZr for H₂ from methane via POM: Sr loading & optimization†

Norah Alwadai,^a Abdulaziz A. M. Abahussain,^{Id}^b Dharmesh M. Vadodariya,^c Khaled M. Banabdwain,^b Anis Hamza Fakieha,^b Jehad K. Abu-Dahrieh,^{Id}^d Naif S. Almuqati,^e Ahmad M. Alghamdi,^f Rawesh Kumar ^{Id}^{*c} and Ahmed S. Al-Fatesh ^{Id}^{*b}

Achieving remarkable H₂ yield with significantly high H₂/CO over Ni-based catalysts through partial oxidation of methane (POM) is a realistic approach to depleting the concentration of CH₄ and using H₂ and CO as synthetic feedstock. This study examined Ni catalysts on titania–zirconia for methane conversion via POM at 600 °C and atmospheric pressure. The addition of strontium to the catalyst was explored to improve its performance. Catalysts were characterized by X-ray diffraction, Raman-infrared-UV-vis spectroscopy, and Temperature-programmed reduction-desorption techniques (TPR, TPD). 2.5 wt% Sr addition induced the formation of the highest concentration of extreme basic sites. Interestingly, over the unpromoted catalyst, active sites are majorly generated by hardly reducible NiO species whereas upon 2.5 wt% promoted Sr promotional addition, most of active sites are derived by easily reducible NiO species. 45% CH₄ conversion and 47% H₂ yield with H₂/CO = 3.5 were achieved over 2.5 wt% Sr promoted 5Ni/30TiO₂ + ZrO₂ catalyst. These results provide insight into the role of basic sites in enhancing activity through switching indirect pathways over direct pathways for POM. Further process optimization was carried out in the range of 10 000–22 000 SV, 0.35–0.75 O₂/CH₄, and 600–800 °C reaction temperature over 5Ni2.5Sr/30TiO₂ + ZrO₂ by using central composite design under response surface methodology. The optimum activity as high as ~88% CH₄ conversion, 86–87% yield of H₂, and 2.92H₂/CO were predicted and experimentally validated at 800 °C reaction temperature, 0.35O₂/CH₄ ratio, and 10 000 space velocity.

1. Introduction

In the current global warming scenario, mitigation of greenhouse gases is urgently needed to save the ecosystem on Earth. Among the greenhouse gases, methane is 25 times more potent than CO₂.¹ Catalyst communities across the globe are trying to develop a proper catalytic route for the conversion of CH₄. The catalytic direct decomposition of CH₄ into C and H₂ is struggling due to massive carbon decomposition and quick

deactivation. Oxidant-assisted oxidation of CH₄ also gives way to continuous oxidation of carbon deposits into the syngas (H₂ and CO). In dry reforming of methane (DRM), CO₂ is the oxidant; in the steam reforming of methane (SRM), H₂O is the oxidant; and in partial oxidation of methane, O₂ is the oxidant for CH₄ oxidation (eqn (1)–(3)). The typical stoichiometric H₂/CO ratio in DRM, POM, and SRM is 1, 2, and 3, respectively.

According to the stoichiometry of the POM reaction, the H₂/CO ratio over the POM reaction should be equal to 2. But recently, >3H₂/CO ratio during POM reaction has drawn marked attention.^{2,3} It indicates the presence of indirect reaction pathways along with the direct POM pathway (Fig. 1) The indirect reaction pathway of POM can be summarized as the total oxidation of CH₄ into “CO₂ and H₂O” (Fig. 1, step 1) followed by the involvement of “CO₂ and H₂O” into the oxidation of CH₄ through DRM (Fig. 1, step 2a) and SRM reaction (Fig. 1, step 2b)

respectively. The total oxidation of CH_4 is catalysed by NiO , whereas POM, DRM, and SRM are catalysed by metallic Ni .⁴ Overall, the direct and indirect pathways of POM decide the final production distribution.

CH_4 and O_2 undergo control oxidation over B_2O_3 -based catalysts and form formate species which is not dissociated further.⁵ Ru dispersed over Al_2O_3 ($\text{Ru}/\text{Al}_2\text{O}_3$) carried out the complete oxidation of CH_4 and O_2 into syngas. However, adding Re to $\text{Ru}/\text{Al}_2\text{O}_3$ catalyses CH_4 and O_2 to control oxidation into formate species, which dissociates into syngas.⁶ Combining noble metals like Rh, Ru, or Pd with a less expensive metal like nickel creates highly effective catalysts for (POM) reactions. Still, the usual high cost of catalysts is a significant limitation in practical applications.⁶⁻⁸ Selecting proper supports and promoters for Ni-based catalysts may be as efficient as noble metal-based catalysts. Ni supported over lantana and Ni supported over titania have little life span due to the oxidation of active sites Ni by support lantana or titania.⁹⁻¹¹ The partial coverage of active sites by diffusion of TiO_2 and partial phase transformation of titania phase were also reported.¹² The alumina support may be a suitable carrier for Ni catalysts, but the acidic nature of alumina may be less interactive with acidic CO_2 gas. So, one route of POM's indirect pathway (step 2a) may be affected. If we select essential support like MgO for the dispersion of Ni, The Ni/MgO catalyst was found to be more prompt to total oxidation of methane than partial oxidation.⁹ Ni has less dispersion over silica than zirconia.¹³ Even ZrO_2 and yttria-stabilized- ZrO_2 efficiently carry out POM reactions.¹⁴ Over yttria-stabilized- ZrO_2 , both CH_4 and O_2 undergo control oxidation and form formate species, which further break down into syngas. That means it favours the direct methanation route. Again, Ni-supported over ZrO_2 has a higher H_2 uptake than Ni-supported over CeO_2 .¹⁰ The support ZrO_2 has phase transition issues at high temperatures, and Ni-supported over ZrO_2 may be seriously affected by metal sintering. Overall, ZrO_2 and TiO_2 support have excellent redox properties. Their mobile lattice

oxygen is easily accessible in an oxidation reaction, which can minimize the time delay in oxygen transport in POM reaction. However, individually, both have a severe phase transition, and titania has excessive diffusion and active sites' oxidation issues. We have recently developed titania-modified ZrO_2 support, and the new hybrid support has eliminated all the challenges of phase transition, excessive diffusion, and over-oxidation.¹⁵ When different types of promoters (Ce, Cs, and Sr) were added, Ni distributed over titania-modified zirconia (Ni/TiZr) continually maintained an H_2/CO ratio of >3 for 300 minutes on stream.³ Sr addition over Ni/TiZr caused the highest activity due to the maximum concentration of active sites and the higher edge of reducibility. Cs addition over Ni/TiZr resulted in inferior catalytic activity due to the lowest density of basic sites. The enhanced reducibility was also observed upon the promotional addition of Sr over $\text{Ni}/\text{ZrO}_2\text{-Al}_2\text{O}_3$ catalyst.¹⁶ The addition of Sr increases the basicity of the surface, which interacts with more acidic gases like CO_2 in the indirect POM pathway and helps in the activation of CO_2 . Further, a large size of Sr can stabilize CO_2 over the catalyst surface as a bidentate carbonate intermediate, as well as enhance the dissociation of C-H by surface oxygen species.¹⁷ Sr^{+2} -mediated CO_2 was found to be a better oxidizing agent, inhibiting the deposition of carbyne-type carbon.¹⁵ So, it is necessary to extend the research on the different loadings of Sr promoters over Ni/titania-zirconia catalysts toward POM. After proper catalyst selection, the next step is to set reaction conditions/experimental factors (like temperature, O_2/CH_4 ratio, and space velocity) to get maximum H_2 yield with a high H_2/CO ratio. Performing fresh reactions after varying reaction conditions in order to optimize activity needs much time, workforce, and expenditure. With the help of statistical tools like response surface methodology (RSM), the optimum activity can be predicted with a very high level of accuracy by few experimental data. The activity is collected as the response of a mathematical equation that considers all the experimental factors and their interactions.¹⁸ In dry reforming reaction, central composite design and Box-Behnken design under RSM are investigated where predicted values and experiment values are found very close to each other.¹⁹⁻²³ However, for POM reactions, such statistical investigations are less considered and need to be explored by the catalytic community.

Herein, titania modified- ZrO_2 is investigated for supporting catalytic active site "5 wt% Ni" and promoter "1-3 wt% Sr" in the target of limiting phase transition of ZrO_2 and restricting the diffusion for " TiO_2 " and stabilizing the CO_2 intermediate in favor of POM reaction. The catalysts are characterized by surface area-porosity measurement, X-ray diffraction, Raman, infrared, ultraviolet-visible spectroscopy, H_2 -temperature-programmed reduction, and O_2 -temperature-programmed oxide experiments, and CO_2 -temperature programmed desorption. The thorough characterization and catalytic activity reveal the role of Sr promoter for inducing phase stability and edge and strength of reducibility-basicity of $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst in the favour of POM reaction. The best catalyst is further investigated in process optimization by using a central composite design under response surface methodology in the range of 10 000–22 000 SV, 0.35–0.75 O_2/CH_4 , and 600–800 °C reaction temperature.

2. Experimental

2.1 Materials

$\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ (purity 98%, Alfa Aesar), $\text{Sr}(\text{NO}_3)_2$ (Aldrich), 30 wt% TiO_2 –70 wt% ZrO_2 (Daiichi Kigeno Kagaku Kogyo Co.). As per the specification of 30 wt% TiO_2 –70 wt% ZrO_2 (from Daiichi Kigeno Kagaku Kogyo Co., Ltd), it has a tetragonal- ZrO_2 phase and diffuse anatase- TiO_2 phase. The surface area of the 30 wt% TiO_2 –70 wt% ZrO_2 is $124 \text{ m}^2 \text{ g}^{-1}$, and 50% of the particles in the catalyst are smaller than 8.6 nm ($D_{50} = 8.6 \text{ nm}$).

2.2 Catalyst preparation

5 wt% equivalent of $\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ aqueous solution and 1–3 wt% equivalent of $\text{Sr}(\text{NO}_3)_2$ solution nitrate aqueous solution is added over 30 wt% TiO_2 –70 wt% ZrO_2 under stirring at 80 °C temperature. Stirring continues until the solution evaporates and the mixture turns into a paste. The solution was dried at 110 °C for 24 hours and then calcined at 600 °C for three hours. The catalyst is abbreviated as $\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ and $\text{Ni}_x\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ ($x = 1, 2, 2.5, 3$ wt%).

2.3 Catalyst characterization

The BET surface area Powder X-ray diffraction (XRD) analysis of fresh catalyst was conducted by Rigaku (Miniflex) diffractometer using $\text{Cu K}_{\alpha 1}$ radiation ($\lambda = 0.15406 \text{ nm}$) operated at 40 mA and 40 kV. The N_2 adsorption–desorption and porosity results were obtained using a Micromeritics Tristar II 3020 surface area analyzer. 0.2–0.3 g of catalyst was degassed, and all samples were degassed before analysis using the Barrett, Joyner & Halenda (BJH) method. Temperature-programmed hydrogen reduction ($\text{H}_2\text{-TPR}$) and temperature-programmed carbon dioxide desorption ($\text{CO}_2\text{-TPD}$) measurements were performed on a chemisorption device (Micromeritics AutoChem II) by using a thermal conductivity detector over 70 mg catalyst sample, respectively. In $\text{H}_2\text{-TPR}$, H_2 absorption is monitored up to 1000 °C under 10% H_2/He gas, whereas in $\text{CO}_2\text{-TPD}$, CO_2 desorption is monitored upon raising the temperature to 800 °C under 10% CO_2/He gas. The transmission electron microscopy was conducted at 200 kV using an aberration-corrected JEM-ARM200F (JEOL) with a CEOS corrector. The spent catalyst sample underwent Raman analysis within the 1250–3000 cm^{-1} range using a Laser Raman Spectrometer (JASCO, Japan) with a 532 nm beam excitation and 1.6 mW laser intensity. The exposure time was set to 10 seconds with 3 accumulations.

2.4 Catalyst activity test

The partial oxidation of methane was carried out over a 0.1 g catalyst in a tubular stainless-steel fixed bed reactor (PID Eng. & Tech, 9 mm I.D.). The temperature for the catalytic reaction was provided by the cylindrical furnace circumference of the catalyst bed. The temperature at the catalyst bed was monitored by an axially fixed K-type thermocouple in the catalyst bed. In the target of creating active sites before partial oxidation of methane, a reductive pretreatment of the catalyst was carried out under hydrogen (flow rate 30 mL min^{-1}) for 1 h at 800 °C. Further, to

remove the hydrogen gas from the catalyst bed, the reactor was purged with N_2 . Then, the temperature of the reactor was stabilized at 600 °C for the POM reaction. The reaction gas mixture which consisted of 50% CH_4 , 25% O_2 , and 25% N_2 gases was allowed to pass through the fixed catalyst bed with the total flow maintained at 24 mL min^{-1} and $14\,400 \text{ mL g}^{-1} \text{ h}^{-1}$ space velocity. The products were analysed by a gas chromatograph equipped with a propak Q column, molecular sieve columns, and a thermal conductivity detector. The composition of effluent gases was calculated by the normalization method, and the equations for the determination of CH_4 conversion, CO_2 conversion, H_2 yield, CO yield, and H_2/CO ratio are used as follows:

$$\text{CH}_4 \text{ conversion (\%)} = \frac{\text{CH}_{4,\text{in}} - \text{CH}_{4,\text{out}}}{\text{CH}_{4,\text{in}}} \times 100 \quad (4)$$

$$\text{CO}_2 \text{ yield (\%)} = \frac{\text{mol of CO}_2 \text{ in products}}{\text{mol of CH}_4 \text{ in feed}} \times 100 \quad (5)$$

$$\text{H}_2 \text{ yield (\%)} = \frac{\text{H}_{2,\text{out}}}{2 \times \text{CH}_{4,\text{in}}} \times 100 \quad (6)$$

$$\text{CO yield (\%)} = \frac{\text{mole of CO in product}}{\text{mol of CH}_{4,\text{out}} + \text{mol of O}_{2,\text{in}}} \times 100 \quad (7)$$

$$\frac{\text{H}_2}{\text{CO}} = \frac{\text{mole of H}_2 \text{ produced}}{\text{mole of CO produced}} \quad (8)$$

3. Result and discussion

3.1 N_2 physisorption

The N_2 adsorption isotherm and surface parameters (surface area, pore volume, and pore diameter) of $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ and $5\text{Ni}_x\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ ($x = 1, 2, 2.5, 3$) catalysts are shown in Fig. 2 and Table 1. The adsorption–desorption profile of $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ and $5\text{Ni}_x\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ ($x = 1, 2, 2.5, 3$) catalysts are characterized by type IV adsorption with H_1 hysteresis loop which indicates the presence of mesoporous domains of the cylindrical architect.^{24,25} For such isotherm, a desorption branch is recommended for pore size analysis,²⁶ and the “ $\text{dV/dlog}(w)$ ” vs. “ w ” (“ w ” is pore width) plot shows pore size distribution. The $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ has a maximum surface area ($124 \text{ m}^2 \text{ g}^{-1}$), pore volume ($0.36 \text{ cm}^3 \text{ g}^{-1}$), and an average 8.6 nm pore diameter. The catalyst has a bimodal distribution of pore size in the range of 7.0 nm and 10.2 nm. Interestingly, upon promotional addition of Sr over $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$, the pore size distribution becomes narrower and monomodal in the 6.3–6.8 nm range. The pore volume remains almost intact upon the addition of Sr promoters over the $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst. Upon adding 1–2 wt% Sr loading over $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$, the surface area of the catalyst is decreased marginally. The $5\text{Ni}_2\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst has a minimum surface area ($119 \text{ m}^2 \text{ g}^{-1}$) but a maximum pore diameter of 8.6 nm among the promoted samples.

3.2 X-ray diffraction

The X-ray diffraction study of fresh and spent $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ and $5\text{Ni}_x\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ ($x = 1–3$ wt%) catalysts are shown in

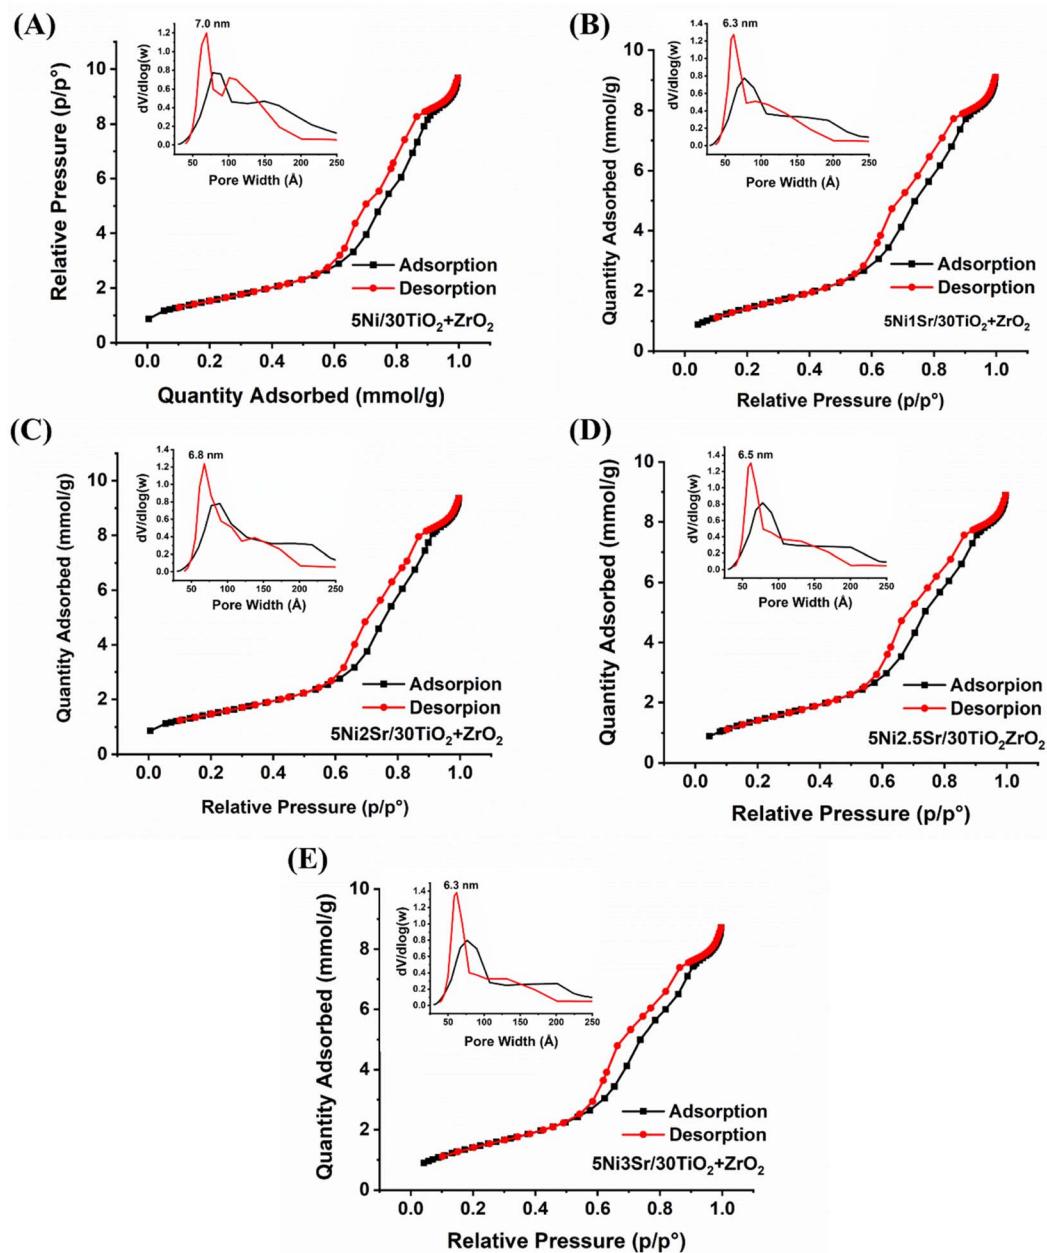

Fig. 2 N_2 adsorption isotherm and porosity distribution (inset figure) of $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ and $5\text{Ni}x\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ ($x = 1\text{--}3$ wt%) catalysts.

Table 1 Surface area, pore volume, and average pore size of $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ and $5\text{Ni}x\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ ($x = 1\text{--}3$ wt%) catalysts

Catalyst	Surface area ($\text{m}^2 \text{g}^{-1}$)	Pore volume ($\text{cm}^3 \text{g}^{-1}$)	Average pore diameter (nm)
$5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$	124	0.36	8.6
$5\text{Ni}1\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$	123	0.36	7.8
$5\text{Ni}2\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$	119	0.37	8.6
$5\text{Ni}2.5\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$	122	0.36	7.8
$5\text{Ni}3\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$	121	0.35	7.6

Fig. 3. Fresh $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst has intense tetragonal ZrO_2 phase (at Bragg's angle $2\theta = 30.28^\circ, 35.15^\circ, 43.05^\circ, 50.50^\circ, 53.60^\circ, 60.32^\circ, 62.76^\circ$; JCPDS reference number 00-034-0180), anatase TiO_2 phase (at Bragg's angle $2\theta = 25.28^\circ, 47.76^\circ, 53.60^\circ, 63.77^\circ$; JCPDS reference number 01-071-1168) and cubic NiO phase (at Bragg's angle $2\theta = 43.20^\circ$; JCPDS reference number

$27.51^\circ, 35.15^\circ, 53.60^\circ$; JCPDS reference number 00-034-0180), anatase TiO_2 phase (at Bragg's angle $2\theta = 25.28^\circ, 47.76^\circ, 53.60^\circ, 63.77^\circ$; JCPDS reference number 01-071-1168) and cubic NiO phase (at Bragg's angle $2\theta = 43.20^\circ$; JCPDS reference number

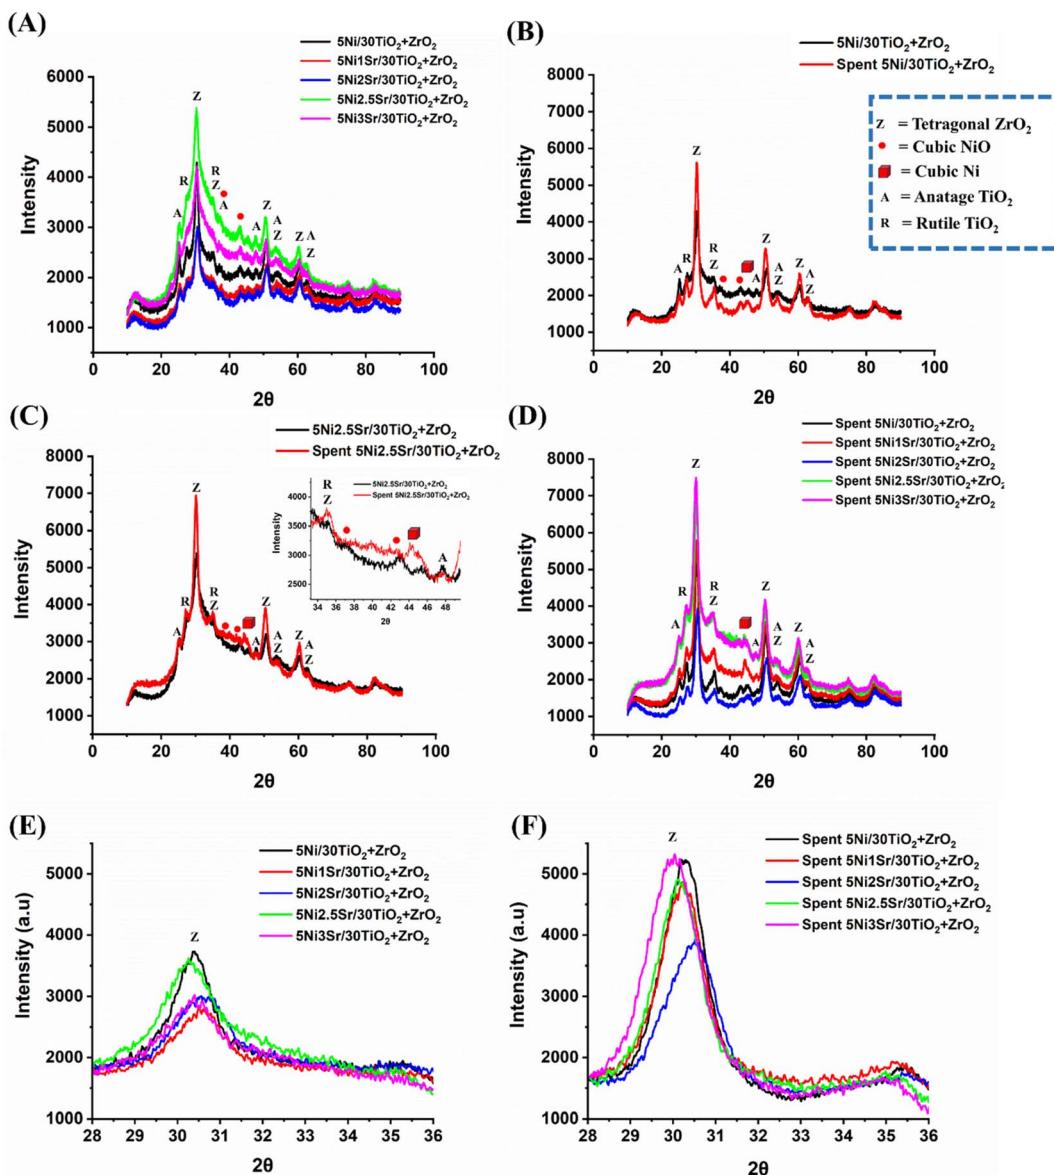

Fig. 3 (A) Fresh XRD of all catalysts, (B) fresh-spent XRD of $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$, (C) fresh-spent XRD of $5\text{Ni}2.5\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$, (D) spent XRD of all catalysts, (E) fresh XRD peak of ZrO_2 about 30.5° Bragg's angle (F), spent XRD peak of ZrO_2 about 30.5° Bragg's angle.

00-047-1049). The crystalline phases for promoter oxides are not observed over Sr-promoted catalysts, which indicates the fine dispersion of promoter oxide. The X-ray diffraction intensity for ZrO_2 and TiO_2 phases is found to be a maximum of over 2.5 wt% Sr promoted $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst compared to other catalysts. The loading above 2.5 wt% Sr over $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ results in a fall of crystallinity of ZrO_2 and TiO_2 phases. Over-spent catalysts, the diffraction pattern for metallic cubic Ni (44.68° ; JCPDS reference number 00-004-0850) appears, and the peak intensity of tetragonal ZrO_2 , Rutile TiO_2 and Anatase TiO_2 phases are intensified. During the POM reaction, the crystalline peak intensity of tetragonal ZrO_2 is grown slowest over 2 wt% Sr promoted $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ than the rest of the catalyst (Fig. 3E and F). It indicates the role of the promoter on support's crystallinity during the POM reaction.

3.3 Raman, infrared and ultra-violet spectra

The Raman spectra of $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ and $5\text{Ni}x\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ ($x = 1, 2, 2.5, 3$) catalyst are shown in Fig. 4A. The Raman band at 395 cm^{-1} (B_{1g}), 517 cm^{-1} (A_{1g} , B_{1g}), 642 cm^{-1} (E_g) are observed for anatase TiO_2 phases whereas the Raman band at 834 cm^{-1} (B_{2g}) signifies for rutile phase.^{27,28} The intensity of the anatase phase is higher than the rutile phase over titania-zirconia-supported Ni catalyst. Previously, it was reported that incorporating zirconia atom into titania lattice stabilized the anatase phase.^{27,29} The Raman band at 283 cm^{-1} and 642 cm^{-1} may be associated with partially tetragonal zirconia and partially by segregated TiO_2 phases, or it may be related to $(\text{ZrTi})\text{O}_x$ material. Sr addition over $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst is found to induce the Raman vibration pattern incredibly. Upon addition of just 1 wt% Sr over $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$, the E_g vibration

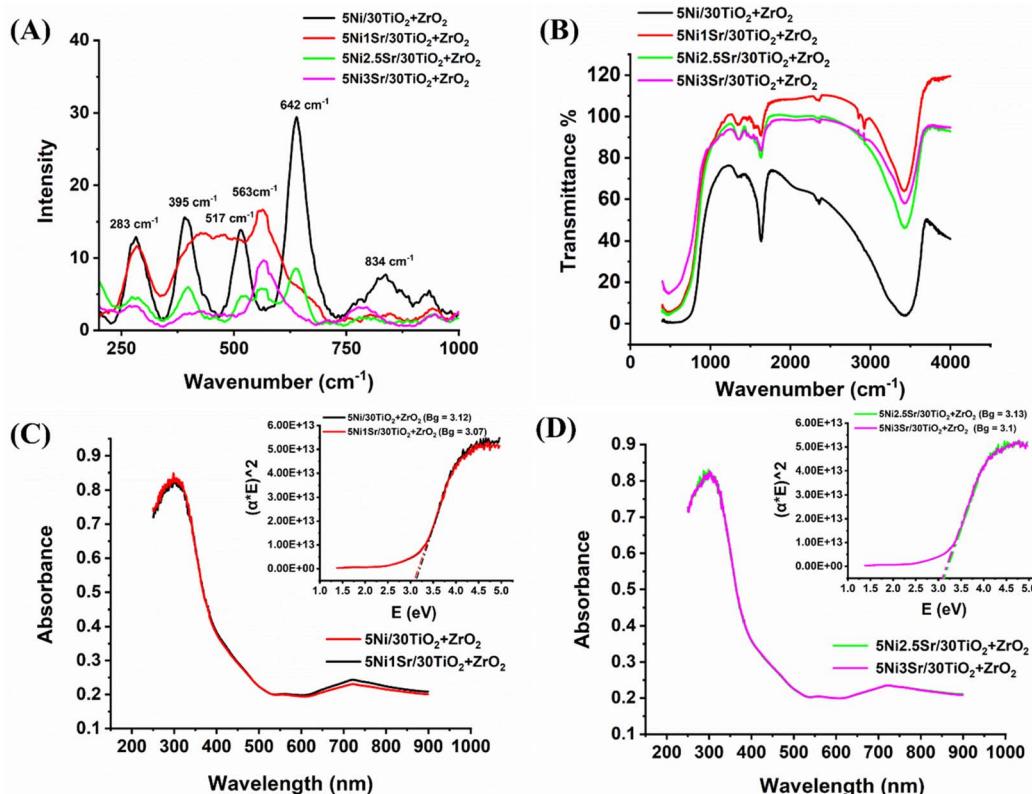

Fig. 4 (A) Raman spectra, (B) infrared spectra (full range), (C) ultra-violet spectra of $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ and $5\text{Ni}1\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ catalysts, (D) ultra-violet spectra of $5\text{Ni}2.5\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ and $5\text{Ni}3\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ catalysts.

band for anatase TiO_2 (at 642 cm^{-1}) and the B_{2g} vibration band for rutile phase (834 cm^{-1}) is suppressed, and the new Raman vibration band about 550 cm^{-1} for amorphous ZrO_2 phase is appeared.²⁷ Upon further loading of Sr up to 3% over $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$, the intensity of most of the Raman bands declined sharply. Sr addition over $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ diminishes the degree of polarizability greatly. Infrared spectra reveal that upon Sr loading, the intensity of the O-H vibration peak (stretching vibration at 2435 cm^{-1} and bending vibration at 1638 cm^{-1}) is decreased sharply (Fig. 4B). The depletion of surface hydroxyl's intensity upon Sr loading may be due to the formation of Sr-O-M (M = Ti, Zr, Ni) by condensation of SrOH and MOH (M = Ti, Zr, Ni). Even at simple atmospheric conditions, the unpromoted catalyst ($5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$) shows the vibration band bidentate formate at 1355 cm^{-1} whereas Sr promoted $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst has a vibration band for both bidentate formate at 1355 cm^{-1} and ionic carbonate at 1460 cm^{-1} (Fig. 4B).^{30,31} Sr incorporation does not alter the material's UV absorption properties or the energy gap between its valence and conduction bands (Fig. 4C and D). The bandgap in all catalysts remains at about 3.1 eV. That means Sr addition doesn't affect the electronic transition pattern over the catalyst surface.

3.4 H₂-temperature and CO₂-temperature programmed profiles

The H₂-temperature programmed reduction study of $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ and $5\text{Ni}x\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ ($x = 1, 2, 2.5, 3$) catalysts are

shown in Fig. 5A. The reduction profile of the catalyst at different temperatures indicates the extent of the interaction of reducible species with support. A peak in the reduction process is observed around $600\text{ }^\circ\text{C}$. This suggests the reduction of nickel oxide (NiO) species that moderately interacted with the ESI.^{† 32} The CO₂-temperature programmed desorption profile of $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ and $5\text{Ni}x\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ ($x = 1, 2, 2.5, 3$) catalysts is shown in Fig. 5B and Table S1.[†] The CO₂ desorption profile of the $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst system is populated with weak basic sites centered at about $100\text{ }^\circ\text{C}$ and moderate strength basic sites presented by a broad peak in the range of 150 to $400\text{ }^\circ\text{C}$. The first peak (about $100\text{ }^\circ\text{C}$) is due to the desorption of CO₂ from surface hydroxyl (constituting weak basic sites), whereas the second peak is due to the desorption of CO₂ from surface oxide ions (constituting moderate strength basic sites).³³⁻³⁶ Upon addition of 1 wt% Sr over $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst, the intensity of moderate strength basic sites increases, and a new desorption peak centered about $475\text{ }^\circ\text{C}$ also appears. It can be termed as a strong basic site constituted by bonded carbonate species (by Sr²⁺) over the catalyst surface.³⁷ Overall, it can be said that CO₂ interaction over the catalyst surface is increased at various basic sites upon the addition of basic Sr oxide. Upon 2 wt% Sr loading over $30\text{TiO}_2 + \text{ZrO}_2$, the CO₂ desorption peak at $420\text{ }^\circ\text{C}$ disappeared, and a diffuse peak at about $730\text{ }^\circ\text{C}$ appeared, which can be termed as extreme basic sites. $730\text{ }^\circ\text{C}$ is reported for the decomposition temperature of SrCO₃.³⁸ Over $5\text{Ni}2\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst, it can also be noticeable that when a new peak of about $730\text{ }^\circ\text{C}$ is

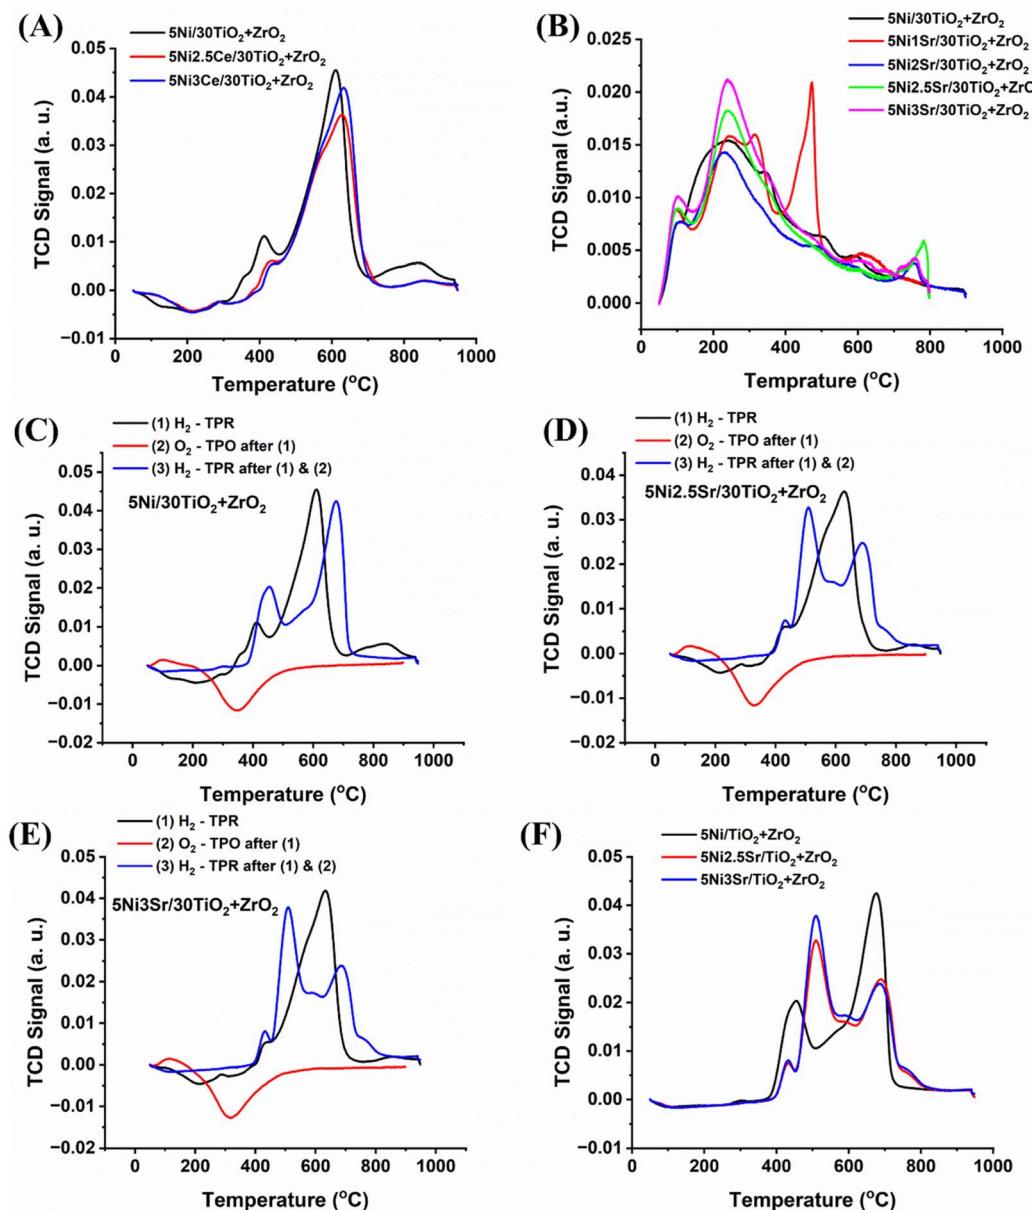

Fig. 5 (A) H₂-temperature programmed reduction profile of 5Ni/30TiO₂ + ZrO₂ and 5NixSr/30TiO₂ + ZrO₂ (x = 1, 2, 2.5, 3) catalysts, (B) CO₂-temperature programmed desorption profile of 5Ni/30TiO₂ + ZrO₂ and 5NixSr/30TiO₂ + ZrO₂ (x = 0, 1, 2, 2.5, 3) catalysts. (C) Cyclic H₂-TPR-O₂-TPO-H₂-TPR profile of 5Ni/30TiO₂ + ZrO₂, (D) cyclic H₂-TPR-O₂-TPO-H₂-TPR profile of 5Ni2.5Sr/30TiO₂ + ZrO₂, (E) cyclic H₂-TPR-O₂-TPO-H₂-TPR profile of 5Ni3Sr/30TiO₂ + ZrO₂, (F) the final H₂-TPR (from cyclic H₂-TPR-O₂-TPO-H₂-TPR profile) of 5Ni/30TiO₂ + ZrO₂ and 5NixSr/30TiO₂ + ZrO₂ (x = 2.5, 3) catalysts.

surged, the intensity of weak basic sites and moderate strength basic sites are not grown. This can be attributed to the engagement of SrO with CO₂ and forms SrCO₃, constituting an extreme basic site over the catalyst surface³³. Further loading of Sr (2.5 wt%), weak basic sites, moderate strength basic sites, and extreme basic sites are grown. With increasing the Sr loading further to 3 wt%, both weak basic sites and moderate strength basic sites are grown, but the intensity of extreme basic sites declined. Overall, the basic site concentration is grown upon Sr loading over and 5Ni/30TiO₂ + ZrO₂ catalyst and 5Ni3Sr/30TiO₂ + ZrO₂ have the highest amount of basic sites (Table S1†).

POM is carried out over a reduced catalyst system where metallic Ni is the active site. However, it should be noticed that in POM, O₂ is the oxidizing gas that can oxidize metallic Ni into NiO which turns the active sites inactive. In POM, H₂ gas is coming out as a reaction product. It is reducing gas also and it can further reduce NiO into Ni. The presence of O₂ and H₂ may bring an oxidation-reduction cycle during the POM reaction which may change the reduction profile of the catalyst. To understand the reduction profile and rearrangement of the reduction profile under oxidizing gas (O₂) and reducing gas (H₂) during POM, an H₂-TPR-O₂-TPO-H₂-TPR cyclic experiment is carried out.

After sequential reduction–oxidation–reduction treatment (by H_2TPR – O_2TPO – H_2TPR cyclic experiment) of $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst, the reduction peak is shifted to the higher temperature (from 640°C). More interestingly, a new reduction peak of relatively less intensity appeared at about 400°C which is attributed to NiO species having weak interaction with the support (Fig. 5C). That means a major part of NiO species undergoes stronger metal–support interaction and some parts of NiO interact with weak interaction. The high-temperature peak (640°C) is reduced hardly whereas the low-temperature reduction peak (400°C) is easily reducible. Interestingly if 2.5–3 wt% Sr promoted $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ catalysts are sequentially tested for reduction–oxidation–reduction

treatment (by H_2TPR – O_2TPO – H_2TPR cyclic experiment), the low-temperature reduction peak is magnified than the high-temperature peak (Fig. 5D–F). It indicates that over $5\text{Ni}2.5\text{Sr}/10\text{TiO}_2 + \text{ZrO}_2$ and $5\text{Ni}3\text{Sr}/10\text{TiO}_2 + \text{ZrO}_2$ catalysts, the amount of easily reducible NiO is more than hardly reducible NiO species. So, $5\text{Ni}2.5\text{Sr}/10\text{TiO}_2 + \text{ZrO}_2$ and $5\text{Ni}3\text{Sr}/10\text{TiO}_2 + \text{ZrO}_2$ catalysts have more active sites which is derived from easily reducible NiO and available from early temperature ranges.

3.5 Catalytic activity results

Generally, zirconia has prominent monoclinic phases, which are unstable, and in the same way, titania has both anatase and rutile phases. Interestingly, 30 wt% titania–70 wt% zirconia has only

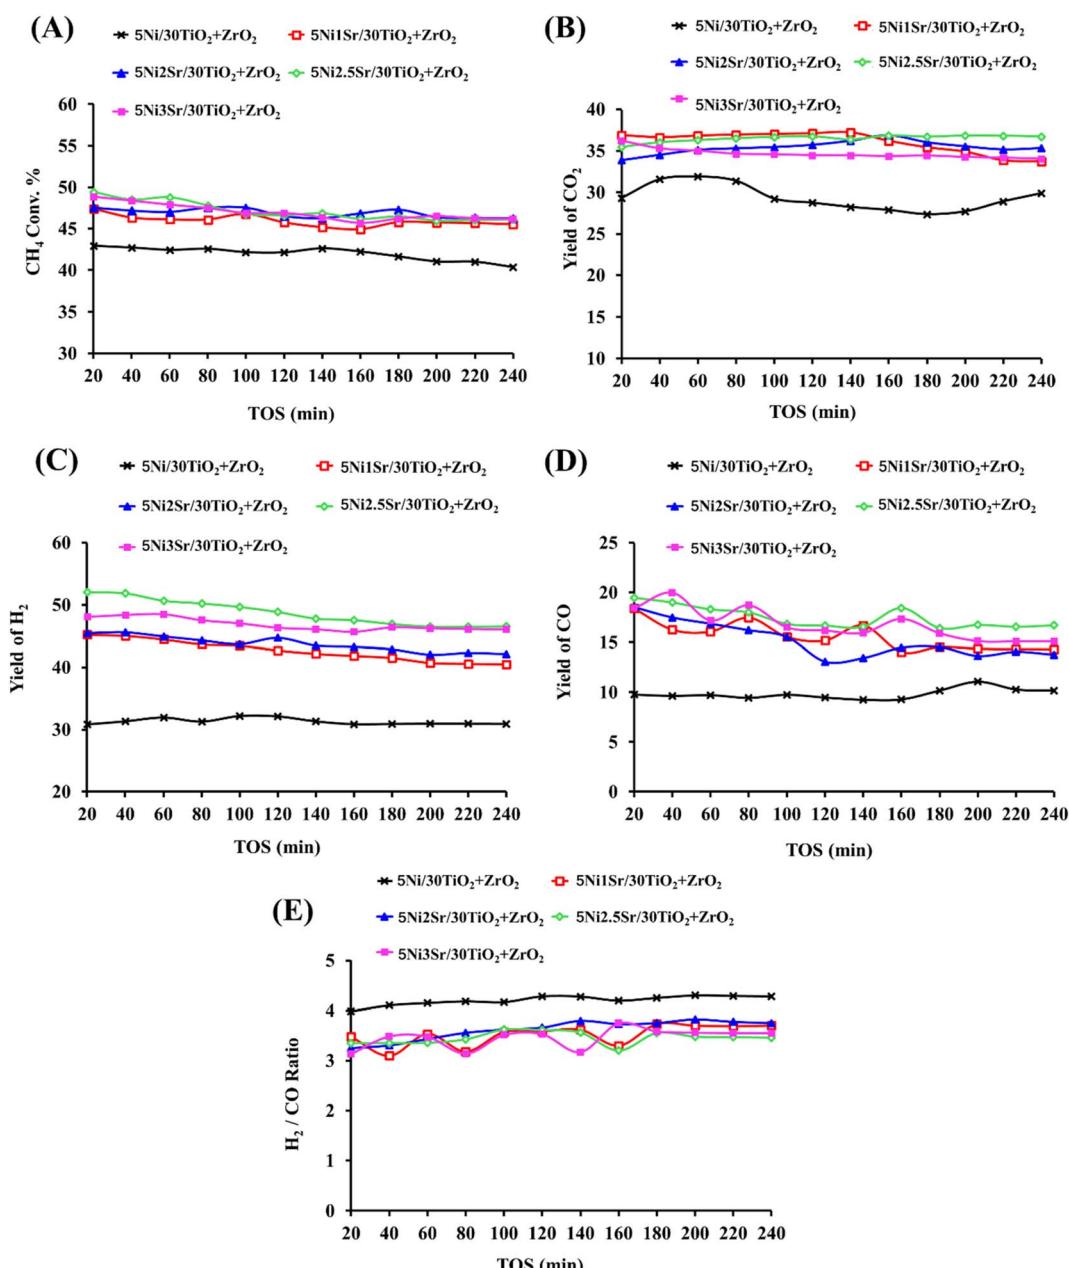

Fig. 6 Time on stream of the catalytic activity results of $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ and $5\text{Ni}x\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ ($x = 1, 2, 2.5, 3$) catalysts (A) CH_4 conversion (%), (B) CO_2 -yield (%), (C) H_2 -yield (%), (D) CO yield (%), (E) H_2/CO ratio.

a stable tetragonal zirconia phase and anatase titania phases. That means the presence of titania stabilizes the tetragonal phase of zirconia, whereas the incorporation of zirconia into the titania crystal stabilizes the anatase phase of titania.^{27,29} The stable phases of titania–zirconia make it a good choice for supporting the active site “Ni” for partial methane oxidation.

The catalytic activity in terms of CH_4 conversion, H_2 yield, CO yield and H_2/CO ratio, and CO_2 yield over $\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ and $\text{Ni}_x\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ ($x = 0, 1, 2, 2.5, 3$) catalysts are shown in Fig. 6. NiO is stabilized over a $30\text{TiO}_2 + \text{ZrO}_2$ catalyst with moderate strength (as verified by H_2 -TPR). The $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst is reduced before POM in the target of preparing active sites “Ni” for POM reaction. Under the oxidizing gas stream O_2 (which is one of the feeds of POM) and reducing gas stream H_2 (which is one of the products of POM), active sites are reorganized and major of the active sites (Ni) is generated by the reduction of hardly reducible NiO . $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst achieves 43–40% CH_4 conversion during 240 minutes time on stream. In the mean of product distribution, ~30% H_2 yield ($\text{H}_2/\text{CO} \sim 4$) and ~30% CO_2 yield was maintained for up to 240 minutes on stream. From here, two points should be discussed in more depth. The first one is “equal H_2 yield and CO_2 yield” over a $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst. It indicates the presence of both partial oxidation and total oxidation of methane over titania–zirconia supported Ni catalyst. Jin *et al.* observed that CH_4 was catalysed over metallic Ni surface and gave only gaseous H_2 , whereas NiO catalyses CH_4 and gives CO , CO_2 , and H_2O .⁴ That means NiO is an active site for total oxidation of methane and oxidation of metallic Ni into NiO (by O_2) can be easily predicted during POM.^{39–41} Overall, the *in situ* concentration of both Ni and its oxide (NiO) decides the participation of CH_4 in partial oxidation, in total oxidation, or both. The second point is that the mole of H_2 is about 4 times the mole of CO over an unpromoted catalyst. If H_2 and CO come from a POM reaction over a $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst, the stoichiometric ratio of H_2/CO may not be more than 2. This indicates that H_2 is also generated by other reaction pathways. This means, the total oxidation reaction takes place and the CO_2 and H_2O produced will react with methane in dry reforming and steam reforming, respectively.⁴² These pathways are known as indirect pathways of POM.⁴³ Overall, the H_2/CO ratio ~ 4 indicates the increased participation of indirect pathways of POM compared to direct pathways. The water gas shift reaction ($\text{CO} + \text{H}_2\text{O} \rightarrow \text{CO}_2 + \text{H}_2$) is also feasible in this temperature range (600 °C) and it may also increase H_2/CO ratio.^{2,44,45}

Further, in search of optimum product yield, promotional addition of 1–3 wt% Sr is carried out over $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst where Sr is stabilized over catalyst surface by $\text{Sr}-\text{O}-\text{M}$ ($\text{M} = \text{Ti}, \text{Zr}, \text{Ni}$) bond. Adding Sr over $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst brings narrower pore size distribution and enhances the formation of stronger basic sites over the catalyst surface. 1 wt% Sr over $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst may be specified with the presence of strong basic sites (bonded carbonate species by Sr^{+2}), whereas 2–3 wt% Sr promoted $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$ has the presence of extreme basic sites (due to SrCO_3). $5\text{Ni}2.5\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst has the highest population of extreme basic sites among others. During the POM reaction, the active sites are distributed with different interactions with support in the presence of oxidizing gas (O_2) and reducing gas (H_2). H_2 -TPR- O_2 -TPO- H_2 cyclic profile shows that upon addition of 2.5 wt% Sr over $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$, the amount of easily reducible NiO is increased than hardly reducible NiO . So, active sites generated by easily reducible NiO are exposed for POM from a quite early temperature. The CH_4 conversion is enhanced to 47% and 50% over $5\text{Ni}1\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ and $5\text{Ni}2.5\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ catalysts, respectively. However, at the end of 100 minutes, CH_4 conversion over both catalysts reached to 45%. However, at the end of 240 minutes; $5\text{Ni}2.5\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst achieved optimum catalytic activity in mean of higher H_2 yield (47%) and CO_2 yield (37%) than $5\text{Ni}1\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst (H_2 yield = 40%, CO_2 yield = 34%). This indicates that extreme basic sites over $5\text{Ni}2.5\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ catalysts induce POM reactions more towards indirect pathways than $5\text{Ni}1\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ catalysts. The H_2/CO ratio over $5\text{Ni}2.5\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ catalyst is equal to 3.5 which indicates the precise presence of indirect pathways of POM. Upon further loading of Sr (3 wt%) over $5\text{Ni}/30\text{TiO}_2 + \text{ZrO}_2$, the active sites distribution profile is similar than $5\text{Ni}2\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$. The concentration of extreme basic sites decreases, whereas the concentration of moderate strength basic sites has grown. Overall, the catalytic activity over $5\text{Ni}3\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ is found to be relatively inferior to $5\text{Ni}2.5\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$. $5\text{Ni}3\text{Sr}/30\text{TiO}_2 + \text{ZrO}_2$ showed 46% CH_4 conversion, 34% CO_2 yield, 46% H_2 yield at the end of 240 minutes on stream.

3.6 Process optimization

In the current POM experiment, temperature, O_2/CH_4 ratio, and space velocity are experimental factors that can be adjusted to get the maximum CH_4 conversion, H_2 yield, and H_2/CO ratio. Now a days, central composite design (CCD) under response

Table 2 The actual and dimensionless variable of the experimental factors

Experimental factors	Actual value (lower limit & upper limit)	Centre point of the experiment (\bar{X}_{oi})	Deviation from the centre of the experiment (Δx_i)	Dimensionless variable (X_i)
Space velocity ($\text{ccg}^{-1} \text{h}^{-1}$)	10 000	16 000	6000	−1
	22 000			+1
Temperature (°C)	600	700	100	−1
	800			+1
$\text{O}_2 : \text{CH}_4$	0.35	0.55	0.2	−1
	0.75			+1

surface methodology is utilized frequently in optimization process. It forecasts the optimum response (activity) by using a few experimental data based on variation in experimental factors. Each experimental factor (x_i) has a lower limit ($x_{i\min}$) and an upper limit ($x_{i\max}$). $(x_{i\max} + x_{i\min})/2$ and $(x_{i\max} - x_{i\min})/2$ are described as centre point of the experiment (\bar{X}_{oi}) and the deviation of each limit from center of experiment (Δx_i) respectively. By using \bar{X}_{oi} and Δx_i ; the original value of experimental factors (x_i) are coded into a dimensionless variable (X_i) as $X_i = (x_i - \bar{X}_{oi})/\Delta x_i$. Table 2 lists the actual and coded values of the experimental factors.

RSM predicts the response (\hat{Y}) as per the function of experimental factors modeled under the quadratic polynomial model by using Taylor series expansion as shown below (eqn (9)). The basic terms of statistics related to error metrics (R^2 , APE, MAPE, MAE) are briefed in ESI under heading S2.† To refine the model and identify the significant factors & their interaction; analysis of variance (ANOVA) method for various components was carried out and shown in Table S3.† High F -values, high R^2 values and low P -values indicate that the model terms are significant at approximately the 95% confidence level or at (p -values below 0.05). After excluding the insignificant function, models for CH_4 conversion, yield of H_2 , and H_2/CO ratio have been proposed using Design-Expert software version 13 (eqn (10)–(12)). Based on these models predicted values of response variables are shown in Table 3. The experimental data and the model's predicted data for CH_4 conversion, yield of H_2 , and H_2/CO ratio are shown in Table 3. R^2 values for the expected models of CH_4 conversion, yield H_2 , and H_2/CO are 0.9898, 0.9933, and 0.9870, respectively. Table 3 confirms a strong correlation between predicted values and experimental results, with R^2 's

near 1. Plotting predicted against actual values is crucial for model assessment, with close alignment to the $X = Y$ line indicating a good fit. On average, the predicted values have absolute error of 0.95%, 0.81% and 0.78% compared to the actual values. A lower MAPE value indicates a higher level of accuracy in the models.

$$\hat{Y} = \beta_0 + \sum_{i=1}^3 \beta_i X_i + \sum_{i=1}^2 \sum_{j=i+1}^3 \beta_{ij} X_i X_j + \sum_{i=1}^3 \beta_{ii} X_i^2 + \varepsilon \quad (9)$$

where X_1, X_2, X_3 are the inputs in actual or coded values of the experimental factors, β_0 is intercept coefficient, $\beta_i, i = 1, 2, 3$ are the linear coefficients, β_{ii} are the quadratic coefficients, $\beta_{ij}, j = 1, 2, 3$ are the interaction coefficients and ε is the error term.¹⁸

$$\begin{aligned} \widehat{X_{\text{CH}_4}} = & -591.47685 + 1.65087A + 35.51705B - 0.000983C \\ & - 0.001006A^2 \end{aligned} \quad (10)$$

$$\begin{aligned} \widehat{Y_{\text{H}_2}} = & -574.48643 + 1.59843A + 29.27866B - 0.000998C \\ & - 0.000964A^2 \end{aligned} \quad (11)$$

$$\begin{aligned} \widehat{\text{H}_2/\text{CO}} = & 5.75664 - 0.01295A + 8.51507B + 0.0000065C \\ & - 0.022312AB + 0.000016A^2 + 5.68404B^2 \end{aligned} \quad (12)$$

where A, B, C represent temperature, O_2/CH_4 ratio and space velocity respectively. $\widehat{X_{\text{CH}_4}}$ is conversion of CH_4 and $\widehat{Y_{\text{H}_2}}$ is yield of hydrogen.

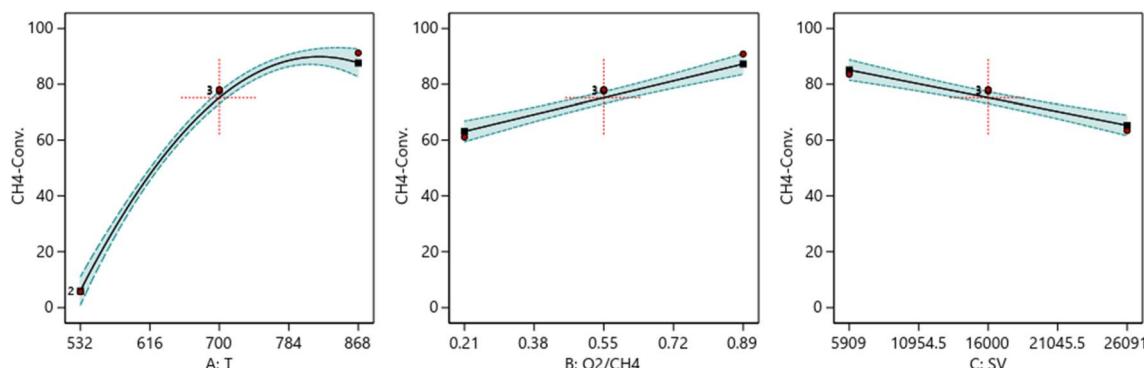

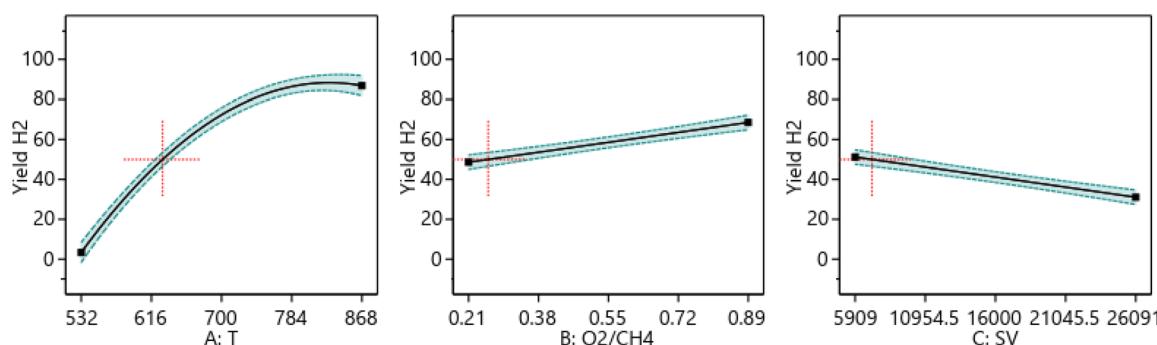

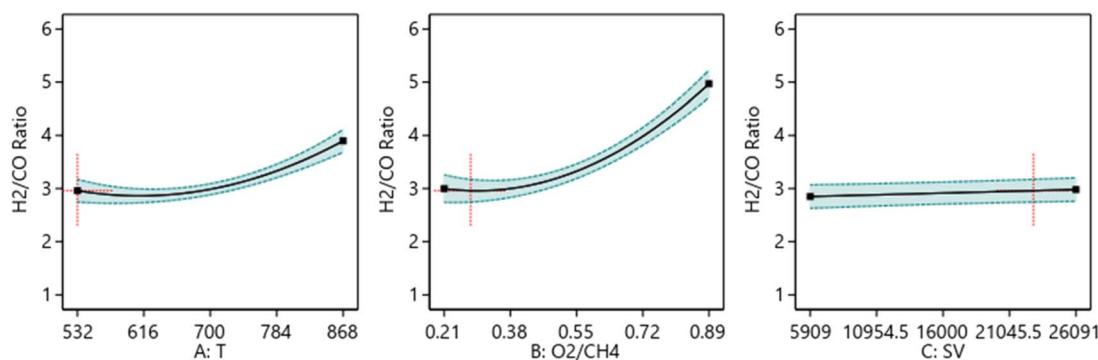

3.6.1 Simulation on design expert program

3.6.1.1 One factor effect (2D) plot. The effect of each process parameter on the reaction responses is shown in Fig. 7–9. Fig. 7 indicates that increasing temperature, increasing the O_2/CH_4

ratio, and decreasing the SV value will increase CH_4 conversion. Fig. 8 indicates that increasing temperature, increasing the ratio and decreasing the SV value will increase Yield H_2 . Fig. 9 indicates that increasing temperature, increasing the ratio and increasing the SV value will increase H_2/CO ratio.

3.6.1.2 Two factors effect (3D plot). One factor effect (2D) Plot is not suitable for assessing the relative impact of each factor due to coefficient scaling, and the intercept doesn't align with the center of the design space. Through the aid of the resulting equations, and design expert program the response surface plots were constructed for the predicted conversion or formation of the various components comprising the reaction system

versus two process variables while keeping the third at a constant level or value as shown in the 3D models in Fig. 10–15. Fig. 10–11 show the three-dimensional response surface plots, which represents the effects of the factors (Temperature, SV, and ratio $\text{O}_2 : \text{CH}_4$) on the variation of CH_4 conversion. Fig. 10 shows the surface plots which represent the relationship between the response variable (CH_4 conversion), and the two factors (Temperature and the ratio $\text{O}_2 : \text{CH}_4$) at $\text{SV} = 16.201$. It is shown with increasing the temperature and increasing the ratio $\text{O}_2 : \text{CH}_4$, the CH_4 conversion increase. Fig. 11 shows the surface plots that represent the functional relationship between a designated response variable (CH_4 conversion), and the two

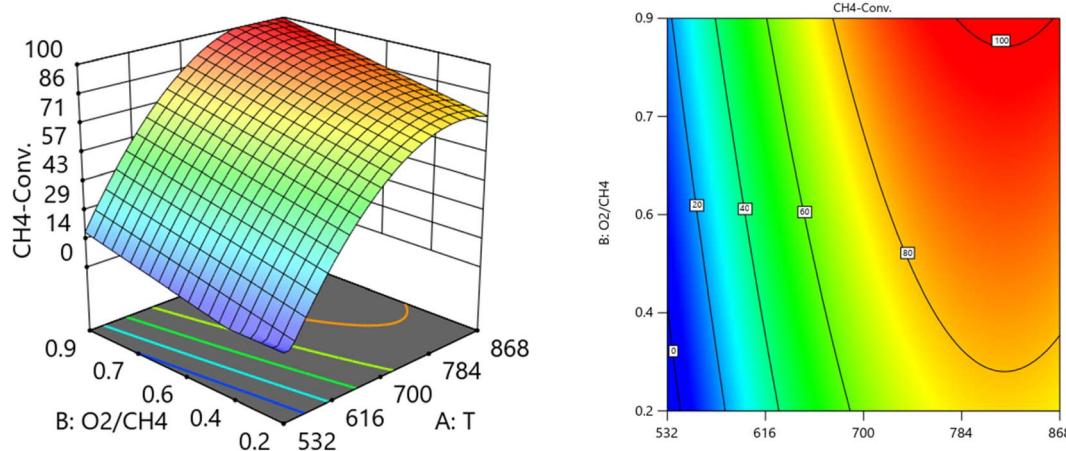

Fig. 10 The relationship between the temperature, ratio, and CH_4 conversion % at $\text{SV} = 16\,201$.

factors variables (Temperature and SV) with $\text{O}_2 : \text{CH}_4$ fixed at 0.6112. The response surface shows with increasing the temperature and decreasing the SV, the CH_4 conversion increases. It was observed to increase from 5.74% at 600 °C to 97.14% at 800 °C. All factors have significant effects but the temperature has the major effect on the variation of CH_4 conversion.

Fig. 12 and 13 show the three-dimensional response surface plots, which represents the effects of the factors (temperature, SV, and ratio $\text{O}_2 : \text{CH}_4$) on the variation of yield of H_2 . Fig. 12 shows the surface plots which represent the relationship between the response variable (yield H_2), and the two factors (temperature and the ratio $\text{O}_2 : \text{CH}_4$) at $\text{SV} = 7119.92$. It is shown that by increasing the temperature and increasing the ratio $\text{O}_2 : \text{CH}_4$, the Yield H_2 increases. Fig. 13 shows the surface plots that represent the functional relationship between a designated response variable (yield H_2), and the two factors variables (temperature and SV) with $\text{O}_2 : \text{CH}_4$ fixed at 0.4888. The response surface shows with increasing the temperature and

decreasing the SV, the yield H_2 increase. It was observed to increase from 3.18% at 600 °C to 96.32% at 800 °C.

Fig. 14 and 15 show the three-dimensional response surface plots, that represents the effects of the factors (temperature, SV, and ratio $\text{O}_2 : \text{CH}_4$) on the variation of H_2/CO . Fig. 14 shows the surface plots which represent the relationship between the response variable (H_2/CO), and the two factors (temperature and ratio $\text{O}_2 : \text{CH}_4$) at $\text{SV} = 23\,000$ at. It is shown the lowest H_2/CO ratio is found at moderate values of both temperature and O_2/CH_4 ratio, which means neither too high nor too low values of both temperature and SV are optimal for minimizing the H_2/CO ratio. Fig. 15 shows the surface plots that represent the relationship between the response variable H_2/CO , and the two factors variables (temperature and SV) with $\text{O}_2 : \text{CH}_4$ fixed at 0.3732. The plot shows that the H_2/CO ratio is firstly influenced by temperature, with higher temperatures leading to lower H_2/CO ratios, the space velocity has a lesser effect. It was observed to increase from 1.63% at 600 °C to 3.36% at 800 °C.

3.6.1.3 Model prediction and validation. Fig. 16 shows optimum predicted simultaneous values of CH_4 conversion,

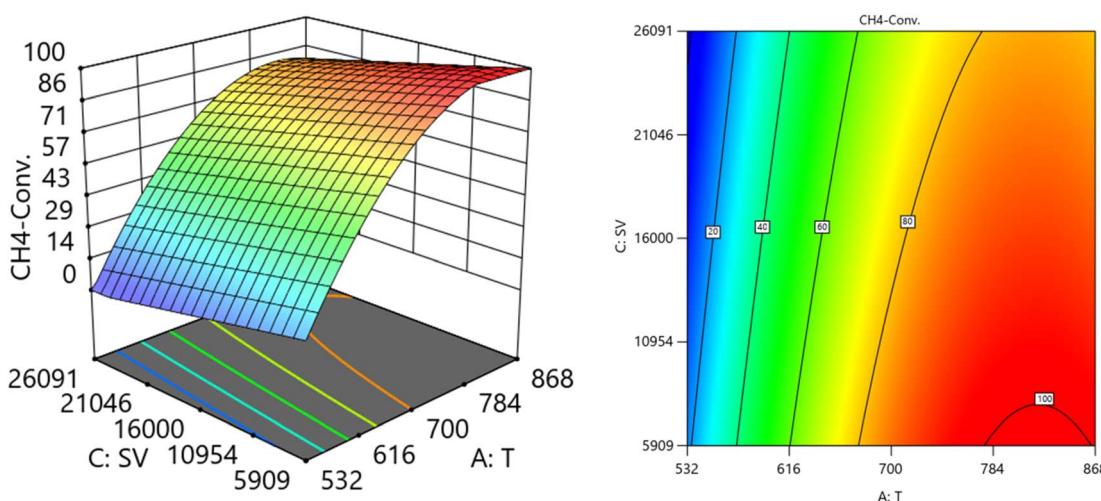

Fig. 11 The relationship between the temperature, SV, and CH_4 conversion % at ratio = 0.6112.

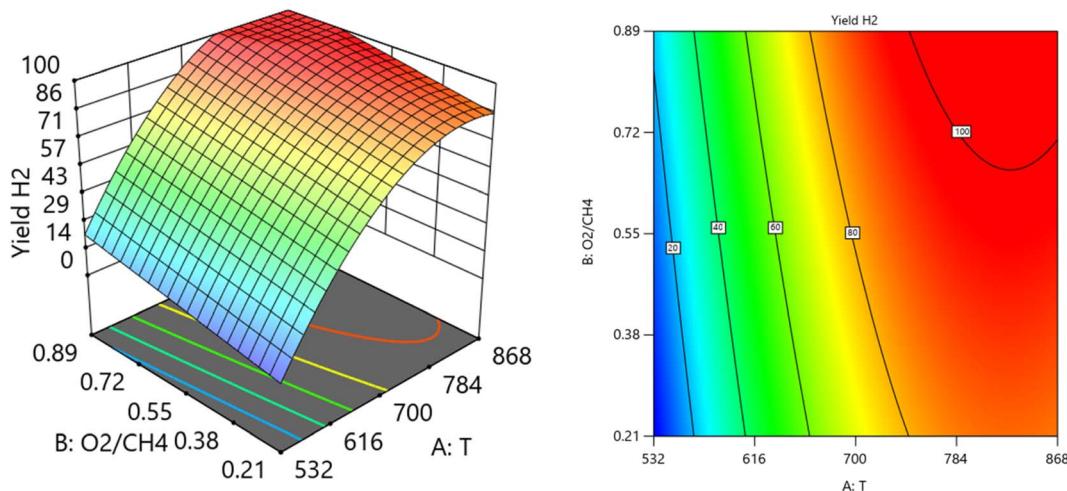

Fig. 12 The relationship between the temperature, ratio, and yield H_2 at $SV = 7119.92$.

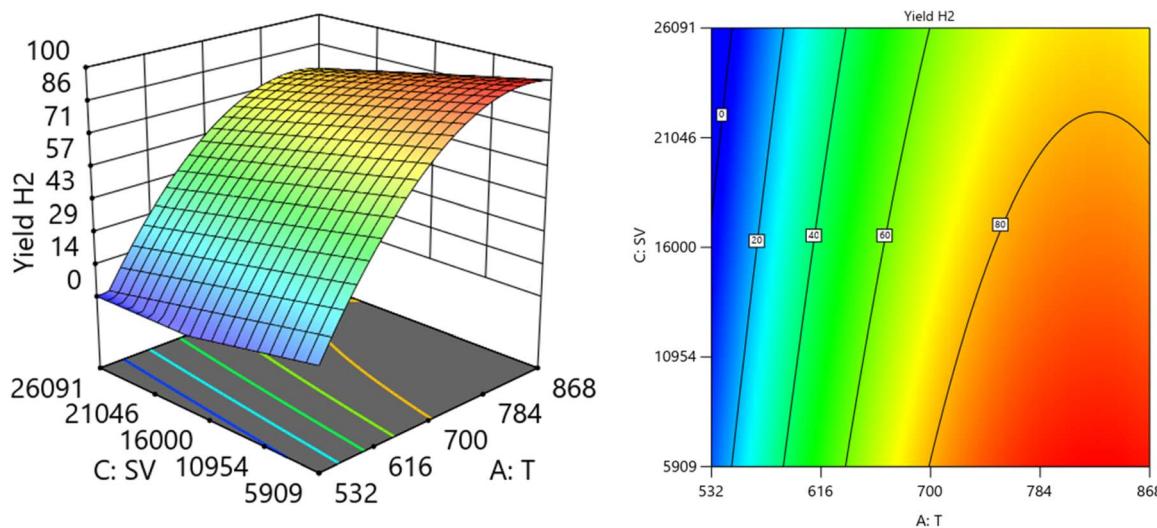

Fig. 13 The relationship between the temperature, SV , and yield H_2 at Ratio = 0.4888.

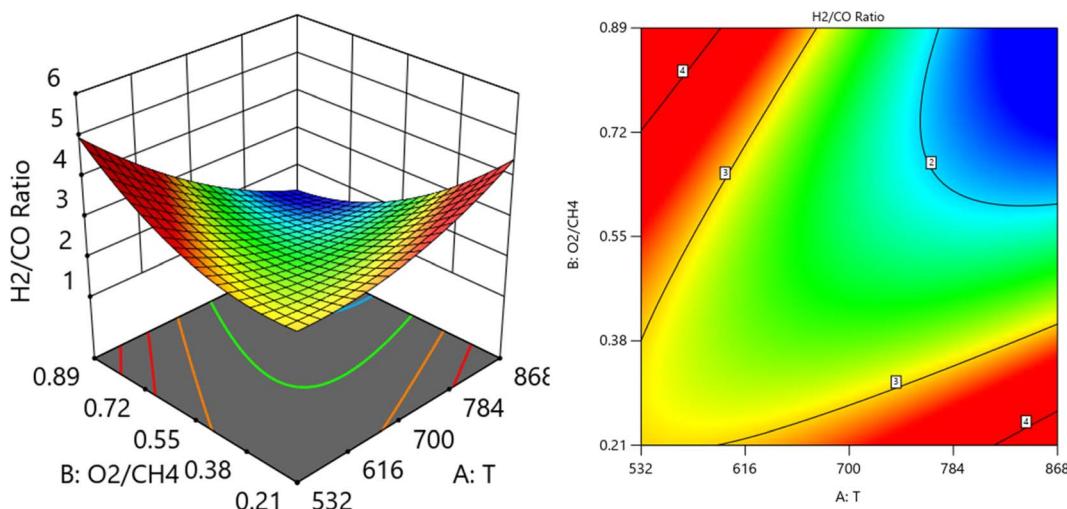

Fig. 14 The relationship between the temperature, ratio, and H_2/CO at $SV = 23\,000$.

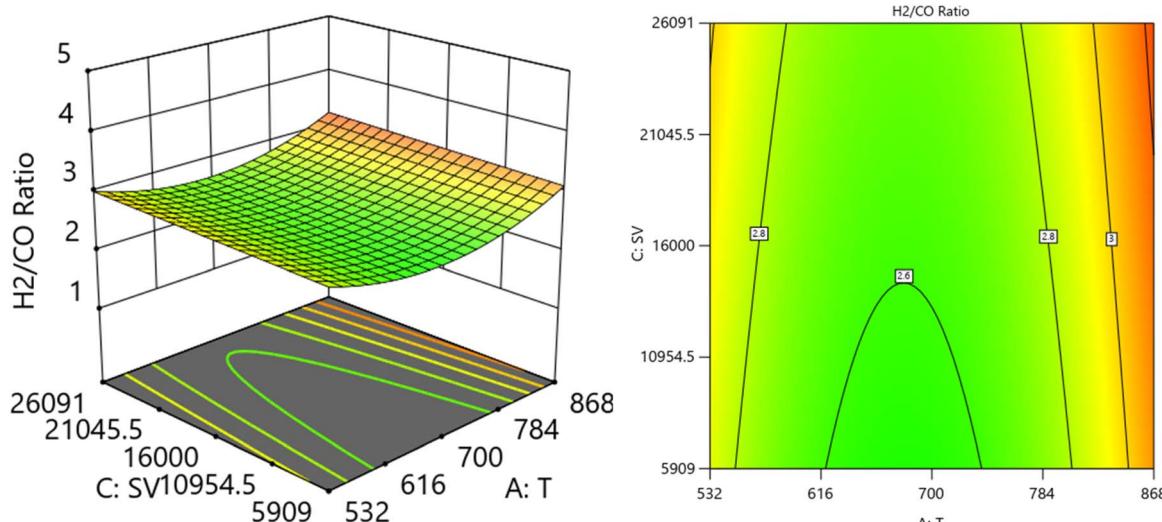

Fig. 15 The relationship between the temperature, SV, and H_2/CO at ratio = 0.3732.

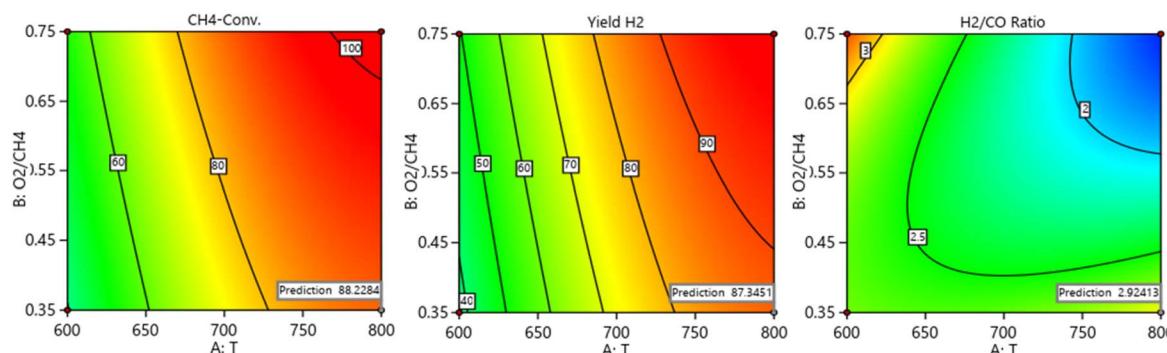

Fig. 16 Optimum predicted simultaneous values of CH_4 conversion, yield H_2 , and H_2/CO ratio.

Table 4 Comparison of theoretical model predictions and experimental findings

Variables							
Objective function: max (CH_4 -conv.) & max (yield H_2) & max (H_2/CO)	Criteria	T Value	$\text{O}_2 : \text{CH}_4$ value	SV value	H_2/CO max.	Yield $\text{H}_2\%$ max.	CH_4 -conv. max.
	Theoretical	800	0.35	10 000	2.924	87.345	88.228
	Experimental	800	0.35	10 000	2.921	86.250	87.850

yield H_2 , and H_2/CO ratio. Table 4 represents the comparison between predicted with experimental findings. The optimum catalytic activity (88.23% CH_4 conversion, 87.35% yield H_2 , and 2.92 H_2/CO) towards POM over 5Ni2.5Sr/30TiO₂ + ZrO₂ catalyst is predicted at 800 °C reaction temperature, 0.35O₂/CH₄ ratio and 10 000 space velocity (SV). At these given reaction conditions, ~88% CH_4 conversion, 86% yield of H_2 , and 2.92 H_2/CO are achieved experimentally. The closeness of prediction results and experimental results validate the effectiveness of theoretical models.

Further, the best catalyst (5Ni2.5Sr/30TiO₂ + ZrO₂) is investigated for long time on stream (28.5 hours) study at 800 °C, 0.35O₂/CH₄ ratio, and 10 000 space velocity (Fig. S1A and B†) and the spent catalyst is characterized with thermogravimetry

analysis (Fig. S1C†). 44% weight loss is observed over spent 5Ni2.5Sr/30TiO₂ + ZrO₂ catalyst after 28.5 h time on stream reaction. But, the CH_4 conversion and H_2 yield remains above than 70% during entire time on stream. That means, active sites for POM remains exposed even after high carbon deposit.

4. Conclusion

30 wt% titania-70 wt% zirconia (30TiO₂ + ZrO₂) support has stable tetragonal ZrO₂ and anatase TiO₂ phases, which can stabilize the catalytic active Ni towards POM reaction. During the POM, the active sites undergo re-organization in the presence of oxidizing and reducing gases (O₂ and H₂). The majority of these active sites are formed from NiO species that are

scarcely reducible. With equal hydrogen (30%) and CO₂ (30%) yields, the 5Ni/30TiO₂ + ZrO₂ catalyst demonstrated 42% CH₄ conversion, suggesting the existence of both partial (producing H₂ and CO) and total (producing CO₂ and H₂O) oxidation. Due to the presence of a sufficient number of basic sites of moderate strength over 5Ni/30TiO₂ + ZrO₂, the total oxidation products (CO₂ and H₂O) interact with the surface, subsequently with CH₄ under indirect pathways and achieve H₂/CO ~4. The promotional addition of 1 wt% Sr over 5Ni/30TiO₂ + ZrO₂ catalyst enhances additional strong basic sites, whereas 2.5 wt% Sr addition over 5Ni/30TiO₂ + ZrO₂ catalyst induces the generation of the highest concentration of extreme basic site. And 5Ni2.5Sr/30TiO₂ + ZrO₂ catalyst contains easily reducible NiO too. The easy reducibility promotes methane conversion whereas extreme basicity triggers an indirect pathway of POM by involving total oxidation products, CO₂ and H₂O, in the oxidation of CH₄. The high yield of hydrogen (47%) with a ratio of hydrogen to carbon monoxide (H₂/CO) of 3.5 suggests that these basic sites promote indirect pathways over direct pathways for methane conversion. Further process optimization is carried out over the best catalyst (5Ni2.5Sr/30TiO₂ + ZrO₂ catalyst) in the range of 10 00–22000 SV, 0.35–0.75 O₂/CH₄, and 600–800 °C reaction temperature by using central composite design under response surface methodology. ~88% CH₄ conversion, 86–87% yield of H₂, and 2.92H₂/CO is predicted and experimentally validated at 800 °C reaction temperature, 0.35O₂/CH₄ ratio, and 10 000 space velocity (SV). Hence, the validation experiment confirmed the correctness of the model since the experimental findings obtained under the expected optimal operating circumstances matched the predicted values pretty well.

Data availability

All data that support the findings of this study are included within the article.

Conflicts of interest

The authors declare that they have no known competing financial interest or personal relationships that could have appeared to influence the work reported in this paper.

Acknowledgements

The authors express their gratitude to Princess Nourah bint Abdulrahman University Researchers Supporting Project (Grant No. PNURSP2024R11), Princess Nourah bint Abdulrahman University, Riyadh, Saudi Arabia. Also the authors would like to extend their sincere appreciation to Researchers Supporting Project number (RSPD2024R612), King Saud University. RK and DMV acknowledge Indus University for supporting research.
