Highly efficient CuNi–ZrO₂ nanocomposites for selective hydrogenation of levulinic acid to γ -valerolactone†

 Yufang Ding,[‡] Junli Sun,[‡] Rongqi Hu, Daiping He,[‡] Xulin Qiu,^{*} Chengying Luo and Ping Jiang[‡]

CuNi–ZrO₂ nanocomposites were prepared by a simple coprecipitation technique of copper, nickel and zirconium ions with potassium carbonate. The structures of the nanocomposites were characterized by N₂ physical adsorption, XRD, H₂-TPR and STEM-EDS. The Cu_{0.05}Ni_{0.45}–ZrO₂ nanocomposite showed outstanding catalytic performance in hydrogenation of levulinic acid (LA) to γ -valerolactone (GVL), especially NaOH solution (0.5 mol L^{−1}) as a solvent. 100% LA conversion and > 99.9% GVL selectivity are achieved over Cu_{0.05}Ni_{0.45}–ZrO₂ catalyst at 200 °C, 3 MPa for 1.5 h. Characterization results suggest that the excellent reactivity of the Cu_{0.05}Ni_{0.45}–ZrO₂ may be due to a better reducibility of nickel oxide in the CuONiO–ZrO₂, dispersion of Ni in the Cu_{0.05}Ni_{0.45}–ZrO₂ compared to nickel oxide in the NiO–ZrO₂ and Ni in the Ni_{0.5}–ZrO₂ and promotion of OH[−]. The results demonstrate that the Cu_{0.05}Ni_{0.45}–ZrO₂ nanocomposite has potential to realize high efficiency and low-cost synthesis of liquid fuels from biomass.

Introduction

Our over-reliance on fossil resources for various chemicals and fuels production has caused global fuel supply deficiency and environmental issues.¹ Transformation of abundant and reproducible biomass to chemicals and fuels can be a promising solution to both issues. Lignocellulose is the most abundant biomass resource on Earth, and is mainly composed of cellulose and lignin. The former can be decomposed into high concentration guaiacol and polyaromatic hydrocarbons by rapid pyrolysis and hydrothermal liquefaction.¹ The latter can be converted into LA, 5-hydroxymethylfurfural and furfural.² These molecules can further be converted into useful chemicals and fuels.^{3,4} Catalytic hydrogenation of LA to GVL has attracted much attention in recent years because of GVL's unique properties of low toxicity, high boiling point, excellent stability and high energy density, and widespread application as a fuel and food additives, green solvent for synthesis of pharmaceuticals, a versatile building block for production of polymers, olefins and other chemicals with high added value.^{5–8}

The hydrogenation of LA to GVL has been reported over both homogeneous and heterogeneous catalysts. The homogeneous catalysts are superior to the heterogeneous catalysts

in catalytic reactivity and selectivity toward GVL, but the use of noble metal (Ru, Pd, Rh, *etc.*) complexes limits their applications, and catalyst recovery after reaction is still a major issue. Considering the advantages of the heterogeneous catalysts in recovery and recyclability, different heterogeneous catalysts have been developed to catalyze the hydrogenation of LA toward GVL. Noble metals (Ru,⁹ Pt,⁹ Pd,¹¹ Ir,¹² *etc.*) on various supports have been reported to effectively catalyze the reaction. Particularly, supported Ru-based catalysts have been widely investigated for the hydrogenation of LA toward GVL because they exhibited excellent hydrogenation activity and selectivity toward GVL.^{13–16} However, the Ru-based catalysts showed deactivation during the LA hydrogenation.^{17,18} Base metal catalysts are usually preferred due to their availability and low price, which are more suitable for large-scale use. Various base metal (Cu,¹⁹ Ni,²⁰ Co²¹) catalysts have been investigated for the LA hydrogenation toward GVL. Rode *et al.* found that the LA could be transformed to GVL with a 100% selectivity on Cu–ZrO₂ catalyst under harsh reaction conditions, *i.e.*, high temperatures (200–265 °C), high pressures (3.0–7.0 MPa H₂) and long reaction times (5–10 h).²² Mohan *et al.* reported that the Ni–SiO₂ catalyst showed a high GVL productivity,²³ whereas the selectivity toward GVL was 87%.

Herein, we reported the hydrogenation of LA toward GVL on Cu_{0.05}Ni_{0.45}–ZrO₂ nanocomposite in a tank reactor. The catalyst showed rather better performance for the hydrogenation of LA to GVL than Ni–ZrO₂, especially Cu–ZrO₂ and Ni–SiO₂ catalysts.

Experimental section

Catalyst preparation

Levulinic acid and $\text{Zr}(\text{NO}_3)_4 \cdot 3\text{H}_2\text{O}$ (99%) were procured from Chengdu Aikeda Chemical Reagent Co. Ltd $\text{Cu}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$ (99%), $\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ (99%) and K_2CO_3 (99%) were obtained from Chengdu Cologne Chemicals Co. Ltd.

The $\text{Ni}_x\text{Cu}_y\text{-ZrO}_2$ nanocomposites with different molar fractions of Cu and Ni ($x + y = 0.5$) were prepared by a coprecipitation technique. Typically, $\text{Cu}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$, $\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ and $\text{Zr}(\text{NO}_3)_4 \cdot 3\text{H}_2\text{O}$ were dissolved in redistilled water according to nanocomposites components and precipitated using 0.2 mol L^{-1} K_2CO_3 solution under stirring at room temperature. The precipitate was separated by filtration and washed with redistilled water to remove soluble ions after aging the precipitate for 5 h. The precipitate thus obtained was dried for 10 h at 110°C and calcined for 4 h at 400°C in an air flow. Then the calcined catalyst was reduced for 2 h at 400°C in a H_2 flow. The $\text{Cu}_{0.05}\text{-ZrO}_2$ and $\text{Ni}_{0.05}\text{-ZrO}_2$ catalysts were prepared in the same manner as that of $\text{Ni}_x\text{Cu}_y\text{-ZrO}_2$. The molar fractions of Cu and Ni in the $\text{Cu}_{0.5}\text{-ZrO}_2$, $\text{Ni}_{0.5}\text{-ZrO}_2$ and $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ were 0.488, 0.493, 0.049 and 0.446 according to ICP-AES determination, respectively.

Catalyst characterization

XRD patterns of catalysts were recorded on a Rigaku D/Max Ultima IVX-ray diffractometer with a 40 kV accelerating voltage and 30 mA current using CuK_α radiation. Their pore structures and specific surface areas were determined *via* N_2 adsorption-desorption on an ASAP 2010 Micromeritics apparatus. Temperature-programmed reduction (TPR) was performed on a Finesorb-3010 chemisorption instrument. 100 mg catalyst was gradually heated to 200°C and held for 2 h, then cooled to 50°C in an argon flow of 50 mL min^{-1} . Then the catalyst was heated to 700°C at 10 K min^{-1} in a H_2/Ar (10% v/v) flow of 40 mL min^{-1} . The effluent gas H_2 is analyzed with a thermal conductivity detector. STEM and EDS measurements were performed on a JEOL JEM 2100 transmission electron microscope at a 200 kV accelerating voltage. XPS spectra were recorded by an X-ray photoelectron spectrometer (ESCALAB 250Xi, AlK_{α} , C 1s 284.6 eV).

Catalytic tests

Hydrogenation of LA was performed in a teflon-lined stainless steel autoclave. In each run, 10 mL of LA aqueous solution (5 wt%) and 15 mg catalyst was used. The autoclave was purged one time with nitrogen and four times with hydrogen, then it was pressurized to the desired hydrogen pressure. The reaction mixture was stirred at 1000 rpm. The products were determined by GC9890 gas chromatography with a capillary column (SE-30) and flame ionization detector using 1-butanol as an internal standard.

Results and discussion

Catalyst characterization

The textural properties of the $\text{Cu}_{0.5}\text{-ZrO}_2$, $\text{Ni}_{0.5}\text{-ZrO}_2$ and $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ catalysts were determined by N_2 physical

adsorption. They showed similar type IV isotherm (Fig. S1†). As displayed in Table S1,† the BET specific surface area, pore volume and mean pore size of the $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ catalyst were $101 \text{ m}^2 \text{ g}^{-1}$, $0.18 \text{ cm}^3 \text{ g}^{-1}$ and 3.7 nm , respectively. They were larger than those of the $\text{Cu}_{0.5}\text{-ZrO}_2$ ($85 \text{ m}^2 \text{ g}^{-1}$, $0.13 \text{ cm}^3 \text{ g}^{-1}$ and 3.6 nm) and the $\text{Ni}_{0.5}\text{-ZrO}_2$ ($94 \text{ m}^2 \text{ g}^{-1}$, $0.16 \text{ cm}^3 \text{ g}^{-1}$ and 3.5 nm).

The XRD patterns of the $\text{Cu}_{0.5}\text{-ZrO}_2$, $\text{Ni}_{0.5}\text{-ZrO}_2$ and $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ catalysts are shown in Fig. 1. For the $\text{Cu}_{0.5}\text{-ZrO}_2$ catalyst, four main diffraction peaks were observed. $2\theta = 30.3^\circ$ correspond to tetragonal ZrO_2 phase (JCPDS17-0923),²⁴ while $2\theta = 43.4^\circ$, 50.4° and 74.2° correspond to the $\text{Cu}(111)$, $\text{Cu}(200)$ and $\text{Cu}(220)$ planes of Cu (JCPDS004-0836).²⁵ For the $\text{Ni}_{0.5}\text{-ZrO}_2$ catalyst, three main diffraction peaks were observed at $2\theta = 30.3^\circ$, 50.6° , 60.1° which is attributed to tetragonal ZrO_2 phase, while $2\theta = 44.3^\circ$ and 76.4° correspond to the $\text{Ni}(111)$ and $\text{Ni}(220)$ planes of Ni (JCPADS#04-0850).²⁶ The $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ catalyst showed two main diffraction peaks of tetragonal ZrO_2 phase and metallic Ni at 30.3° and 44.3° . The characteristic peaks of Cu do not appear in the $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ catalyst. It can be suggested that the Cu are highly dispersed in the nanocomposite. Further analysis of $\text{Ni}(111)$ reflection with Sherrer's equation, it was found that Ni crystallite sizes in the $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ and $\text{Ni}_{0.5}\text{-ZrO}_2$ catalysts are 3.8 nm and 5.7 nm, respectively. The Ni crystallite size in the $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ is smaller than that of the $\text{Ni}_{0.5}\text{-ZrO}_2$, which suggests that the replacement of Cu makes Ni more dispersed in the nanocomposite.

Fig. 2 shows the H_2 -TPR profiles of CuO-ZrO_2 , NiO-ZrO_2 and CuONiO-ZrO_2 . For the CuO-ZrO_2 (Fig. 2a), there was a reduction peak at 200°C , which is ascribed to the reduction of CuO .²⁷ The NiO-ZrO_2 and CuONiO-ZrO_2 show reduction peaks at $328\text{--}505^\circ\text{C}$, which correspond to the reduction of NiO .²⁸ The reduction peak at 505°C is probably ascribed to the NiO with relatively strong interaction with ZrO_2 . For the CuONiO-ZrO_2 , the reduction temperatures of low temperature peaks were obviously lower than those of NiO-ZrO_2 , suggesting that the NiO in the CuONiO-ZrO_2 was more dispersed. The reduction peak at 196°C in the CuONiO-ZrO_2 is ascribed to the reduction of CuO . The reduction temperature is lower than that of CuO in the CuO-ZrO_2 . The relatively low reduction temperature is

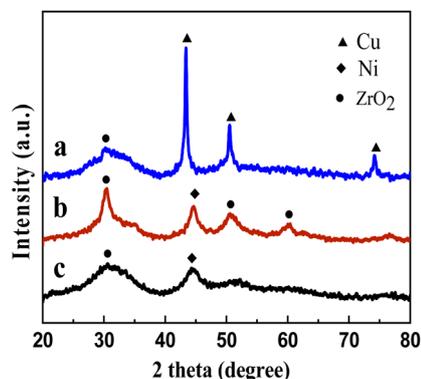

Fig. 1 XRD patterns of the $\text{Cu}_{0.5}\text{-ZrO}_2$ (a), $\text{Ni}_{0.5}\text{-ZrO}_2$ (b) and $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ (c) catalysts.

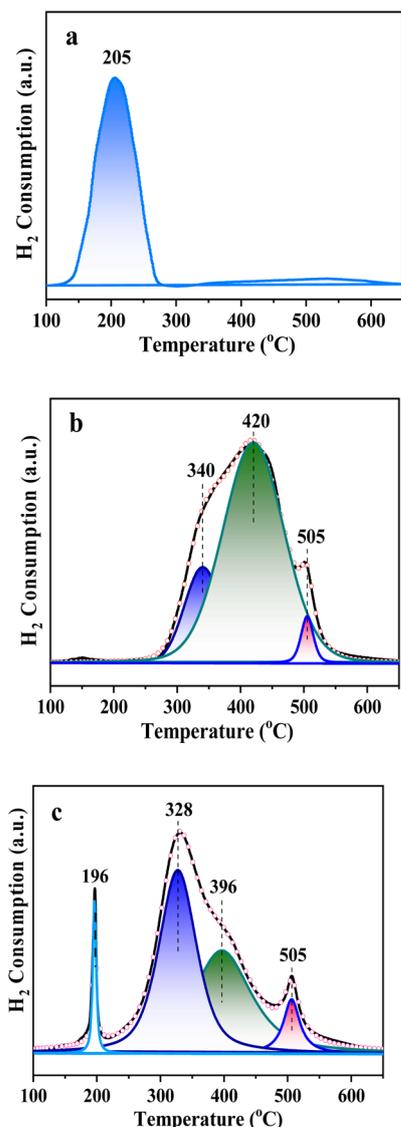

Fig. 2 TPR profiles of the CuO-ZrO_2 (a), NiO-ZrO_2 (b) and CuONiO-ZrO_2 (c) samples.

probably due to high dispersion of CuO in the nanocomposite. These are consistent with the results of XRD characterization.

To further identify the microstructures of Cu , Ni and ZrO_2 , STEM-EDS analysis of the $\text{Cu}_{0.5}\text{-ZrO}_2$, $\text{Ni}_{0.5}\text{-ZrO}_2$ and $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ were carried out. The elemental mapping images of the $\text{Cu}_{0.5}\text{-ZrO}_2$, $\text{Ni}_{0.5}\text{-ZrO}_2$ and $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ show that Cu , Ni are highly dispersed in ZrO_2 (Fig. 3b, g and j). For the $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ nanocomposite, the Ni was evenly separated by Cu and ZrO_2 (Fig. 3l), suggesting better dispersion of Ni in the $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ nanocomposite than that in the $\text{Ni}_{0.5}\text{-ZrO}_2$. This is consistent with the results of XRD and H_2 -TPR characterizations.

XPS analysis was carried out on the $\text{Cu}_{0.5}\text{-ZrO}_2$, $\text{Ni}_{0.5}\text{-ZrO}_2$ and $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ catalysts and the results were shown in Fig. S2 and S3.† The Cu 2p spectra of the $\text{Cu}_{0.5}\text{-ZrO}_2$ and $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ can be deconvoluted into two peaks, respectively (Fig. S2†). The peaks located at 932.4 eV and 933.6 are

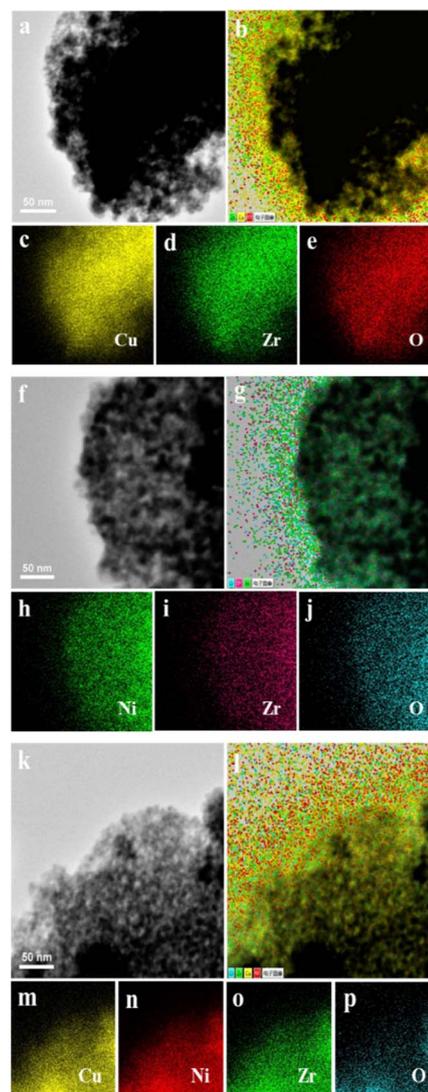

Fig. 3 TEM images and elemental mapping of the $\text{Cu}_{0.05}\text{-ZrO}_2$ (a–e), $\text{Ni}_{0.45}\text{-ZrO}_2$ (f–j) and $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ (k–p) catalysts.

attributed to Cu^0 and Cu^{2+} , respectively.²⁹ This indicates the Cu on the surfaces of the $\text{Cu}_{0.5}\text{-ZrO}_2$ and $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ catalysts was partially oxidized. The Ni 2p spectra of the $\text{Ni}_{0.5}\text{-ZrO}_2$ and $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ can be deconvoluted into two peaks, respectively (Fig. S3†). The Ni 2p_{3/2} peak at 852 eV belongs to Ni^0 , while the Ni 2p_{3/2} peak at 855 eV is assigned to Ni^{2+} .^{30,31} This indicates the Ni on the surfaces of the $\text{Ni}_{0.5}\text{-ZrO}_2$ and $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ catalysts was partially oxidized. The $\text{Ni}^{2+}/\text{Ni}^0$ ratio for the $\text{Ni}_{0.5}\text{-ZrO}_2$ catalyst calculated from their corresponding peak area is 5.11, while the $\text{Ni}^{2+}/\text{Ni}^0$ ratio for the $\text{Cu}_{0.05}\text{Ni}_{0.45}\text{-ZrO}_2$ catalyst is 4.23, indicating that adding a small amount of Cu into the $\text{Ni}_{0.5}\text{-ZrO}_2$ catalyst can inhibit nickel oxidation.

Catalytic performance

The catalytic performances of the $\text{Cu}_{0.5}\text{-ZrO}_2$, $\text{Ni}_{0.5}\text{-ZrO}_2$ and CuNi-ZrO_2 catalysts for LA hydrogenation are summarized in Table 1. The conversions of LA over $\text{Cu}_{0.5}\text{-ZrO}_2$, $\text{Ni}_{0.5}\text{-ZrO}_2$ and CuNi-ZrO_2 catalysts were 12.7%, 33.4% and 48.6% at 200 °C

Table 1 Catalytic performance of the Cu_{0.5}-ZrO₂, Ni_{0.5}-ZrO₂ and CuNi-ZrO₂ for LA hydrogenation^a

Entry	Catalyst	LA conv./%	Sel./%		
			GVL	HVA ^b	PDO ^c
1	Cu _{0.5} -ZrO ₂	12.7	>99.9	0	0
2	Ni _{0.5} -ZrO ₂	33.4	>99.9	0	0
3	Cu _{0.05} Ni _{0.45} -ZrO ₂	48.6	>99.9	0	0
4	Cu _{0.125} Ni _{0.375} -ZrO ₂	41.2	>99.9	0	0

^a Reaction conditions: 15 mg catalyst, 10 mL 5 vol% levulinic acid aqueous solution, 200 °C, 3.0 MPa H₂, 90 min. ^b HVA: 4-hydroxyvaleric acid. ^c PDO: 1,4-pentanediol.

and 3.0 MPa H₂ for 1.5 h, respectively. No reactivity of LA was found in the absence of catalyst. The conversion of LA (33.4%) on Ni_{0.5}-ZrO₂ catalyst is almost 3 times as high as that on Cu_{0.5}-ZrO₂ catalyst (12.7%) under the same operating conditions, suggesting Ni with higher intrinsic reactivity for LA hydrogenation than Cu. Interestingly, when a small amount of Ni (0.05 mol) in the Ni_{0.5}-ZrO₂ catalyst was replaced by Cu, a much higher conversion (48.6%) was achieved under the same reaction conditions. XRD, H₂-TPR and STEM-EDS results show that the replacement of Cu makes NiO in the CuONiO-ZrO₂ easier to reduce and Ni more dispersed in the nanocomposite. We think that the excellent reactivity of the Cu_{0.05}Ni_{0.45}-ZrO₂ may be due to a better reducibility of NiO in the CuONiO-ZrO₂ and dispersion of Ni in the Cu_{0.05}Ni_{0.45}-ZrO₂ compared to NiO in the NiO-ZrO₂ and Ni in the Ni_{0.5}-ZrO₂. Further increasing Cu replacement amount in the Ni_{0.5}-ZrO₂ from 0.05 to 0.125 mol had a negligible effect on LA conversion (Table 1). Therefore, the optimum Ni replacement amount with Cu in the Ni_{0.5}-ZrO₂ was 0.05 molar fraction.

LA hydrogenation to GVL proceeds *via* consecutive reactions of the formation of 4-hydroxypentanoic acid or angelicalactones as intermediates.²⁷ The reaction pathway mostly depends on used catalyst and reaction conditions.^{32,33} Various byproducts such as 1,4-pentanediol (PDO) and 4-hydroxyvaleric acid (HVA) are generated from overhydrogenation of GVL when catalyst selectivity is insufficient.³⁴ Therefore, we pay special attention to identify byproducts in the hydrogenation process of

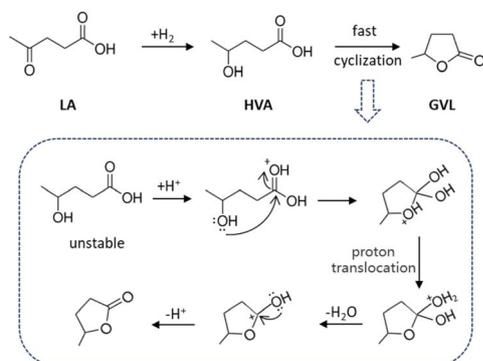

Fig. 4 Reaction pathway for LA hydrogenation to GVL over Cu_{0.05}Ni_{0.45}-ZrO₂ catalyst.

LA using GC-MS. Any byproduct in the reaction mixture is unambiguously detected in our product analysis method. Interestingly, an excellent GVL selectivity (>99.9%) at 100% conversion of LA was obtained on the Cu_{0.05}Ni_{0.45}-ZrO₂ at 200 °C and 3.0 MPa hydrogen pressure. Overhydrogenation of the target product GVL, which was observed over other catalysts,³⁵⁻³⁷ was thoroughly avoided over the Cu_{0.05}Ni_{0.45}-ZrO₂ catalyst (Table 1). It's also worth mentioning that the selectivity of GVL remained at >99.9% throughout the study, which may suggest that the hydrogenation of LA proceeds *via* the formation of unstable HVA, then undergoes rapid cyclization to GVL (Fig. 4). The Cu_{0.05}Ni_{0.45}-ZrO₂ also exhibited catalytic activity superior to that of conventional catalysts (Table S2[†]), showing great potential in sustainable GVL production from LA.

Effect of reaction conditions

We investigated the effects of reaction temperature, H₂ pressure and solvent to ensure the performance of the Cu_{0.05}Ni_{0.45}-ZrO₂ catalyst. Fig. 5 shows the performance of LA hydrogenation at different reaction temperatures over the Cu_{0.05}Ni_{0.45}-ZrO₂ catalyst. Reaction temperature significantly facilitated LA conversion (Fig. 5). When the reaction temperature rises from 180 °C to 210 °C at 3.0 MPa H₂, the conversion of LA increased nearly threefold (from 18.8% to 57.0%). The selectivity of GVL remained at >99.9% throughout the temperature study. No byproducts were detected, which demonstrates that the undesired overhydrogenation of GVL to HVA and PDO can be completely suppressed over the Cu_{0.05}Ni_{0.45}-ZrO₂ catalyst in a broad window (180–210 °C).

The catalytic performance of Cu_{0.05}Ni_{0.45}-ZrO₂ catalyst under different H₂ pressures was evaluated. As displayed in Fig. 6, hydrogen pressure has a remarkable effect on the hydrogenation of LA catalyzed by Cu_{0.05}Ni_{0.45}-ZrO₂. The LA conversion and GVL selectivity were 13.8% and >99.9% at 1.0 MPa H₂, respectively. When the H₂ pressure increased from 1.0 MPa up to 3.0 MPa, the conversion of LA significantly increased from 13.8% to 48.6%, and the unique selectivity to GVL remained at >99.9%, which suggests that high H₂ pressure favor the hydrogenation of LA to GVL on the Cu_{0.05}Ni_{0.45}-ZrO₂ catalyst.

The performance of Cu_{0.05}Ni_{0.45}-ZrO₂ catalyst for LA hydrogenation in polar and non-polar solvents was investigated at

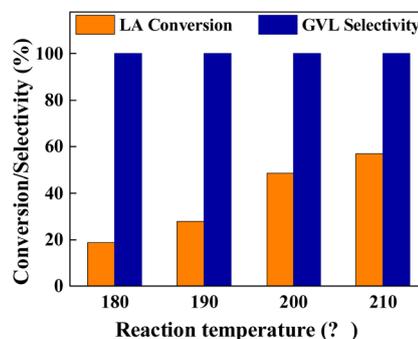

Fig. 5 Catalytic results of the Cu_{0.05}Ni_{0.45}-ZrO₂ for LA hydrogenation at various reaction temperatures.

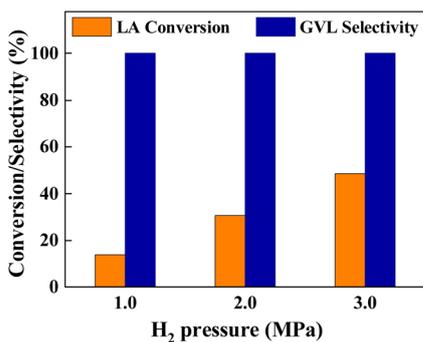

Fig. 6 Catalytic results of the Cu_{0.05}Ni_{0.45}-ZrO₂ for LA hydrogenation at various H₂ pressures.

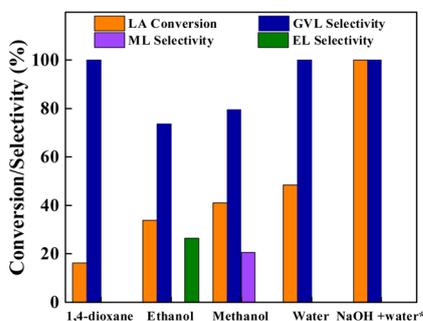

Fig. 7 Catalytic results of the Cu_{0.05}Ni_{0.45}-ZrO₂ for LA hydrogenation in various solvents.

200 °C and 3.0 MPa H₂, and the data are listed in Fig. 7. Non-polar solvent like 1,4-dioxane showed GVL selectivity of >99.9%, but it exhibited low LA conversion of 16.3%. All polar solvents showed good LA conversion with ethanol, methanol and water as solvents. The substrate reactivity is very different in various solvents with the order of water > methanol > ethanol. The water gave excellent GVL selectivity of >99.9%, whereas methanol and ethanol showed below 80% GVL selectivity, which is owing to the formation of methyl levulinate (ML) and ethyl levulinate (EL) byproducts from the esterification of LA with corresponding solvent alcohol. The different reactivities of LA and GVL selectivity in these solvents on Cu_{0.05}Ni_{0.45}-ZrO₂ catalyst suggest that the solvent polarity have impact on the catalytic performance of the Cu_{0.05}Ni_{0.45}-ZrO₂ catalyst. Polar solvent is more beneficial to LA hydrogenation to GVL on Cu_{0.05}Ni_{0.45}-ZrO₂ catalyst. In particular, when a certain amount of NaOH ($n_{\text{NaOH}}/n_{\text{LA}} = 1:5$) was added into the same water, however, a very high LA conversion (100%) was achieved under the same reaction conditions, and an excellent GVL selectivity of >99.9% was obtained.

In order to gain further insight into the promotion of NaOH, the effect of different molar ratios of $n_{\text{NaOH}}/n_{\text{LA}}$ on catalytic performance of Cu_{0.05}Ni_{0.45}-ZrO₂ for LA hydrogenation was investigated at 180 °C and 3.0 MPa H₂ (Table 2). The conversion of LA increased from 18.8% to 46.4% when the molar ratio of $n_{\text{NaOH}}/n_{\text{LA}}$ rose from zero to 1:5. Further increasing molar ratios of $n_{\text{NaOH}}/n_{\text{LA}}$ from 1:5 to 1:2 had a negligible effect on

Table 2 Effect of NaOH on catalytic performance of the Cu_{0.05}Ni_{0.45}-ZrO₂ for LA hydrogenation^a

Entry	$n_{\text{NaOH}}/n_{\text{LA}}$	Conv./%	Sel. %		
			GVL	HVA ^b	PDO ^c
1	0	18.8	>99.9	0	0
2	1:10	30.1	>99.9	0	0

4	1:2	32.9	>99.9	0	0

^a Reaction conditions: 15 mg catalyst, 10 mL 5 vol% levulinic acid aqueous solution, 180 °C, 3.0 MPa H₂, 90 min. ^b HVA: 4-hydroxyvaleric acid. ^c PDO: 1,4-pentanediol.

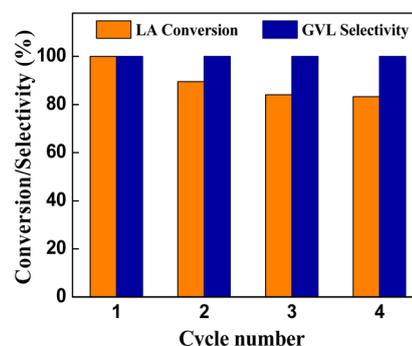

Fig. 8 Reusability of the Cu_{0.05}Ni_{0.45}-ZrO₂ for LA hydrogenation.

the conversion of LA. Therefore, the optimum molar ratio of $n_{\text{NaOH}}/n_{\text{LA}}$ was 1:5. We also studied sodium levulinate hydrogenation to GVL on Cu_{0.05}Ni_{0.45}-ZrO₂ catalyst. The conversion of sodium levulinate is only 1.7% under the same conditions (Table 2), which suggests that an appropriate amount of OH⁻ can improve activity of the Cu_{0.05}Ni_{0.45}-ZrO₂ catalyst for LA hydrogenation to GVL.

Catalyst reusability

We investigated the reusability of the Cu_{0.05}Ni_{0.45}-ZrO₂ catalyst for the LA hydrogenation to GVL at 200 °C, 3.0 MPa H₂ pressure, NaOH solution as a solvent for 1.5 h. After the first LA hydrogenation, the used catalyst was separated, washed using ethanol, dried in vacuum and then used for the next cycle. The results of repeated use three times were shown in Fig. 8. The conversions of LA over fresh, used for second, third, fourth times catalysts were 100%, 89.6%, 84.1% and 83.3%, respectively. After the fourth cycle, the conversion of LA showed a slight downward trend, and the outstanding selectivity of GVL remained at >99.9%. This shows good stability of the catalyst even after 4 cycles.

Conclusions

In summary, we have successfully prepared a highly efficient and reusable Cu_{0.05}Ni_{0.45}-ZrO₂ catalyst for LA hydrogenation to GVL by a simple coprecipitation technique. The LA hydrogenation with Cu_{0.05}Ni_{0.45}-ZrO₂ at 200 °C, 3 MPa for 1.5 h resulted

in 100% LA conversion and >99.9% GVL selectivity, which shows prospects of commercialization. The Ni has higher intrinsic reactivity for LA hydrogenation than Cu, and partly substituting Ni with Cu makes NiO in the CuONiO-ZrO₂ easier to reduce and Ni more dispersed in the nanocomposite, which may be responsible for excellent reactivity of the Cu_{0.05}Ni_{0.45}-ZrO₂. An appropriate amount of OH⁻ can greatly enhance activity of the Cu_{0.05}Ni_{0.45}-ZrO₂ catalyst for LA hydrogenation to GVL.
