Luminescence properties of Bi³⁺/Sm³⁺ co-doped K₃Gd₅(PO₄)₆ phosphors for self-referencing optical thermometry†

 Jing Wang,^a Mingjun Song,^a Junpeng Xue,^b Shala Bi^c and Hyo Jin Seo^d

Potassium gadolinium phosphates [K₃Gd₅(PO₄)₆] co-doped with Bi³⁺/Sm³⁺ phosphors were prepared by traditional solid-state method. Their structure, morphology, luminescence properties, energy transfer, temperature sensing performance and thermal stability have been systematically investigated. The emission and excitation spectra, as well as decay curves were recorded to study the luminescence mechanism. By co-doping Bi³⁺/Sm³⁺, white emission color can be obtained. In addition, the emission intensity ratios of Bi³⁺ and Sm³⁺ ions present excellent temperature sensing performance in a wide temperature range. The maximum relative sensitivities of K₃Gd₅(PO₄)₆ doped with Bi³⁺/Sm³⁺ can reach to 3.13% K⁻¹. In addition, K₃Gd₅(PO₄)₆:Bi³⁺,Sm³⁺ phosphors exhibit high thermal stability of about 55.3% at 423 K compared to room temperature.

1. Introduction

White light-emitting diodes (WLEDs) have been regarded as a promising next generation lighting source due to their advantages of long operation lifetime, low power consumption, small size, good chemical stability, and environmental friendliness.^{1–6} The widely used method for fabricating w-LEDs is to combine a blue LED chip with a yellow YAG:Ce³⁺ phosphor. The major drawback of this method is the lack of red components, resulting in a poor color rendering index and a high correlated color temperature. Recently, another method based on the combination of UV LED chips with blue, green, and red phosphors has been developed. However, this method also suffers from some drawbacks, such as low efficiency (reabsorption between phosphor particles) and high expenses. Therefore, the method by coating single-phased tunable emission phosphors on the UV LED chips has been exploited, which has been an active research area for w-LEDs. In a single-phased phosphor, the tunable emission color, including white, can be obtained by energy transfer from the sensitizer to the activator, and a number of energy transfer systems have been reported, such as Ce³⁺–Eu²⁺,¹ Eu²⁺–Mn²⁺,⁷ Bi³⁺–Eu³⁺,⁸ Ce³⁺–Tb³⁺,⁹ Eu²⁺–

Mn²⁺–Tb³⁺,¹⁰ and Tm³⁺–Dy³⁺,¹¹ *etc.*^{12–14} The rare earth ions are extensively investigated for the modification of luminescence color based on the energy transfer from host or sensitizers. Tunable emission color can be obtained by controlling the dopants of rare earth ions. As is well known, Sm³⁺ can be used as an orange-red emission dopant due to its intense ⁴G_{5/2} → ⁶H₇ transitions. Bi³⁺ can be used as a sensitizer as well as an activator, which has strong absorption in the UV region. Taking into account of ³P₁ → ¹S₀ emission of Bi³⁺ in the blue-green region, it is possible to achieve white emission by combining Bi³⁺ emission with Sm³⁺ emission in a single-phased phosphor.

As one of the basic physical quantities, temperature has an important influence on human daily life and industrial production. In recent years, optical thermometers have attracted wide attention due to their unique advantages of non-contact, fast response, high spatial resolution, and non-invasive operation. Various techniques have been used for the temperature sensing, such as emission intensity, fluorescence intensity ratio (FIR), lifetime, as well as bandwidth. In particular, FIR technique is widely used because of its high accuracy and high resolution. Moreover, it can get rid of the influence of measurement conditions and high equipment and operational requirements. At present, most FIR techniques are based on the detection of two emissions which are from two thermal coupled levels (TCL) of single ions, such as Er³⁺(²H_{11/2}/⁴S_{3/2}),¹⁵ and Dy³⁺(⁴I_{5/2}/⁴F_{9/2}).¹⁶ Whereas, the narrow energy gap between TCL suffers from the drawbacks of low relative sensitivities and large overlap of two emissions. To overcome these drawbacks, the strategies based on the energy transfer or diversity in the thermal quenching behaviors of two luminescence centers have been proposed, such as Pr³⁺–Tb³⁺,¹⁷ Eu³⁺–Tb³⁺,^{18,19} Bi³⁺–Eu³⁺,^{20–22} and Eu³⁺–Dy³⁺.²³ It is known that the emission bands

of Bi³⁺ and Sm³⁺ are basically separated, and signal discrimination can be easily performed.^{24,25} Thus, Bi³⁺/Sm³⁺ co-doped materials have great potential application for temperature sensing.

In the present work, the luminescence properties of Bi³⁺/Sm³⁺ co-doped K₃Gd_{5-x}(PO₄)₆ (host abbreviated as KGP) phosphor is investigated. Tunable emission color can be realized by co-doping Bi³⁺ and Sm³⁺ ions. Meanwhile, Bi³⁺/Sm³⁺ co-doped KGP phosphors can be used for optical temperature sensor in a wide temperature range (44–182 K and 295–523 K) with maximum relative sensitivities of 3.13% K⁻¹.

2. Experimental section

2.1 Synthesis of samples

A series of K₃Gd_{5-x}(PO₄)₆:xBi³⁺ ($x = 0.05, 0.1, 0.15, 0.5, 1, 1.5, 2$, where KGP:Bi³⁺ represents $x = 0.05$), K₃Gd_{4.99}(PO₄)₆:0.01Sm³⁺ (KGP:Sm³⁺), and K₃Gd_{4.96}(PO₄)₆:0.05Bi³⁺, 0.01Sm³⁺ (KGP:Bi³⁺, Sm³⁺) phosphors were prepared by solid state method. Stoichiometric amount of K₂CO₃ (99.9%, Sigma), Gd₂O₃ (99.99%, Sigma), NH₄H₂PO₄ (99.9%, Sigma), Bi₂O₃ (99.9%, Sigma), and Sm₂O₃ (99.99%, Sigma) were carefully weighed and ground thoroughly in an agate mortar with ethanol. The mixture was firstly heated at 873 K for 2 h. The obtained powder was thoroughly mixed in a second time and then heated at 1123 K for 5 h. After cooling down to the room temperature, the white powder was collected for the next investigation.

2.2 Characterization

The XRD patterns were recorded by Rigaku SmartLab X-ray diffractometer in the 2θ range from 10 to 70°. The diffuse reflectance spectra (DRS) were measured by a V-670 UV-Vis/NIR spectrophotometer and BaSO₄ as a background reference. The morphology was studied by JSM-6700F field emission scanning electron microscopy. The emission spectra and decay curves were measured by 266 nm Nd:YAG laser. The excitation spectra were recorded by Quanta Master 300 fluorescence spectrometer equipped with high power Xenon flash lamp. The temperature was controlled by a closed cycle helium cryostat in the range of 11–295 K. The high temperature from 295 to 523 K was done by a home-made temperature control system.

3. Results and discussion

3.1 Crystal structure

Fig. 1(a) shows the XRD patterns of Bi³⁺ single doped and Bi³⁺/Sm³⁺ co-doped KGP phosphors. Fig. 1(b) and (c) shows the crystal structure of the KGP host, which forms monoclinic phase with space group *C2/c*. A three-dimensional Gd₅(PO₄)₆³⁻ anionic framework is formed by Gd polyhedral and P tetrahedral, while K atoms occupy the tunnel along *c* axis. And there are three crystallographic Gd³⁺ sites, of which Gd1 and Gd3 are coordinated by eight O atoms and Gd2 is surrounded by nine O atoms. In Fig. 1(a), all the peaks match well with the ICSD standard card (No. 172528), and no trace of impurity phase can

be observed, revealing the formation of the pure monoclinic *C2/c* phase. With the incorporation of Bi³⁺ and Sm³⁺ ions into host lattice, the crystal structure is not affected. This can be ascribed to the low doping concentration and similar radius of Bi³⁺ (1.17 Å for C.N. = 8), Sm³⁺ (1.079 Å for C.N. = 8, and 1.132 Å for C.N. = 9) with Gd³⁺ (1.053 Å for C.N. = 8, and 1.107 Å for C.N. = 9). The SEM image of Bi³⁺/Sm³⁺ co-doped KGP phosphor is shown in Fig. 2. The particles are in the size range of one to a few micrometers with smooth surface. EDS mapping of KGP:Bi³⁺, Sm³⁺ phosphor is shown in Fig. S1.† Due to the low doping concentration, Bi and Sm elements cannot be detected.

3.2 Luminescence properties

3.2.1 Photoluminescence characteristics KGP:Bi³⁺ phosphor. Fig. 3(a) shows the DRS of KGP host and KGP:Bi³⁺ phosphor in the range from 200 to 1300 nm. In the spectrum of KGP host, a broad absorption band from 200 to 320 nm can be observed, which can be ascribed to the band to band transition of host lattice.^{27,28} An absorption peak at 312 nm can also be found, owing to the ⁸S_{7/2} → ⁶P_{7/2} transition of Gd³⁺ ions.²⁹ When the doping of Bi³⁺, a new absorption band centered at 255 nm appears, which can be attributed to the ¹S₀ → ¹P₁ transition of Bi³⁺ ions.³⁰

The band gaps of the un-doped KGP and KGP:Bi³⁺ phosphors were calculated according to the Kubelka–Munk theory³¹ by using DRS data. The DRS can be transformed into absorption spectra by the following equation:

$$F(R) = \frac{(1-R)^2}{2R} = \frac{K}{S} \quad (1)$$

where R is the diffuse reflectance of the sample, K is the absorption coefficient, and S is the scattering coefficient.

On the basis of Tauc relation, the relation between band gap (E_g) and linear absorption coefficient (α) for direct band gap can be expressed as:

$$\alpha hv = C(hv - E_g)^{1/2} \quad (2)$$

where, hv is the photon energy and C is the proportionality constant. Considering that the scattering coefficient S as a constant with respect to wavelength, and combining eqn (1) and (2), it can be derived that:

$$[F(R)hv]^2 = C(hv - E_g) \quad (3)$$

From the plot of $[F(R)hv]^2$ versus hv , the value of E_g was acquired by extrapolating the linear fitted regions to $[F(R)hv]^2 = 0$, as shown in Fig. 3(b). The band gaps were calculated to be 4.78 and 4.59 eV for KGP and KGP:Bi³⁺. The values are close to K₃Gd(PO₄)₂ (4.8 eV) which has similar structure.³² According to the literature, the doping of luminescent centers can change the band gap energy more or less.²⁷ In this work, the doping of Bi³⁺ can decrease the band gap energy.

The emission spectrum of KGP:Bi³⁺ sample under excitation at 266 nm is shown in Fig. 4(a). The sharp emission peaks at 312 and 624 nm are due to the ⁶P_{7/2} → ⁸S_{7/2} transition of Gd³⁺ ions and its second harmonics, respectively. The broad band from

Fig. 1 (a) XRD patterns of KGP:Bi³⁺ and KGP:Bi³⁺,Eu³⁺ phosphors; (b) and (c) crystal structure of KGP host.²⁶

350 to 600 nm is attributed to the $^3P_1 \rightarrow ^1S_0$ transition of Bi³⁺ ions. Fig. 4(b) shows the normalized excitation spectra of KGP:Bi³⁺ by monitoring the emissions at 410, 445, and 500 nm. Only one excitation band centered at 252 nm ranging from 220 to 280 nm can be found, which is due to the $^1S_0 \rightarrow ^1P_1$ transition of Bi³⁺ ion, and consistent with the absorption band in DRS.³³ Fig. 4(c) shows the emission spectra of KGP:*x*Bi³⁺ (*x* = 0.05–2) phosphors. With increasing Bi³⁺ concentration, the emission intensity increases firstly and then decreases, reaching the maximum at *x* = 0.1. The integral emission intensities of Bi³⁺ ions are shown in Fig. 4(d). It is known that energy transfer between Bi³⁺ ions leads to the concentration quenching. To

confirm the energy transfer mechanism, the critical distance R_c was calculated by following equation³⁴

$$R_c = 2 \left[\frac{3V}{4\pi X_c N} \right]^{1/3} \quad (4)$$

where V is the cell volume of host and is 1998.48 Å³ for K₃Gd₅(PO₄)₆. X_c is the critical concentration of dopant (Bi³⁺) at which the maximum emission intensity is obtained and is 0.1. N is the number of sites available for activators in unit cell and is 4 for K₃Gd₅(PO₄)₆. In this case, the R_c is determined to be 21.21 Å. This value is greater than the shortest distance between the Gd³⁺ ions of 4.10 Å and larger than 5–8 Å, indicating that

exchange interaction is not the main mechanism of concentration quenching. Therefore, the electric multipolar interactions dominate the non-radiative concentration quenching between Bi³⁺ ions. Based on the Dexter theory,³⁵ the type of multipolar interaction can be determined by

$$\frac{I}{x} = \left[1 + \beta(x)^{\frac{\theta}{3}} \right]^{-1} \quad (5)$$

where I is emission intensity, x is doping concentration (Bi³⁺) beyond the optimal value, β is constant, and θ represents the type of multipolar interaction (where $\theta = 6, 8,$ and 10 corresponding to the dipole–dipole, dipole–quadrupole, and quadrupole–quadrupole interactions, respectively). By plotting the relationship between x and I/x in the log–log version, the slope value ($-\theta/3$) of -1.67 can be obtained, as shown in the inset of Fig. 4(d). As a consequence, the value of θ is determined to be 5.01, demonstrating that the dipole–dipole interaction is

Inset shows the correlation between $\log(I/x)$ and $\log(x)$.

Fig. 5 Decay curves of Bi^{3+} ions by monitoring at 445 nm with 266 nm excitation.

responsible for the concentration quenching between Bi^{3+} ions.

The decay curves of Bi^{3+} ions were recorded by monitoring at 445 nm upon the excitation at 266 nm, as shown in Fig. 5. At low doping concentration, the decay curves are single exponential. With increasing Bi^{3+} concentration, the decay curve deviates

from the single exponential characteristic. In this case, the decay times were calculated by the following equation:³⁶

$$\tau = \frac{\int I(t)dt}{\int I(t)dt} \quad (6)$$

where $I(t)$ represents the emission intensity at time t . As shown in Fig. 5, the calculated decay time was reduced from 0.446 to 0.034 μs with increasing Bi^{3+} concentration from $x = 0.05$ to $x = 2$.

Fig. 6(a) shows the temperature dependent emission spectra of $\text{KGP}:\text{Bi}^{3+}$ phosphor in the range of 12 to 294 K. At 12 K, strong Gd^{3+} emission and relatively weak Bi^{3+} emission can be observed, indicating that both host lattice and Bi^{3+} ions can be excited at 266 nm. With the increase of temperature, Bi^{3+} emission intensity shows temperature dependency, as shown in Fig. 6(b). In the 53–204 K temperature range, the enhancement in Bi^{3+} emission intensity at the expense of the Gd^{3+} emission is a result of the competition between two emitting centers.³⁷ The quenching of the Bi^{3+} emission above 204 K is presumably related to the thermal quenching process. Fig. 6(c) displays the decay curves of Bi^{3+} ions. At low temperature, decay kinetics of the Bi^{3+} emission is more complicated than room temperature. Therefore, the lifetime values are calculated based on eqn (6) and displayed in Fig. 6(d). With the increase of temperature, the decay lifetime decrease, which can be fitted by the equation:

$$\tau_T = \frac{\tau_0}{1 + A \exp(-E_a/kT)} \quad (7)$$

herein, τ_T and τ_0 are the lifetimes at temperature of T and initial lifetime, respectively. A is the constant and k stands for Boltzmann constant, and ΔE_a represents the activation energy. As shown in Fig. S2,[†] the activation energy is determined to be 0.049 eV at low temperature range.

3.2.2 Photoluminescence characteristics KGP:Bi³⁺,Sm³⁺ phosphor. Fig. 7(a) exhibits the emission spectra of KGP:Bi³⁺,

KGP:Sm³⁺, and KGP:Bi³⁺,Sm³⁺ phosphors under 266 nm excitation, while Fig. 7(b) presents their CIE diagram. Accordingly, the emission color can be manipulated by controlling the dopants, and white emission color can also be achieved. In emission spectrum of KGP:Sm³⁺, typical Sm³⁺ emissions at 562, 596, and 642 nm can be observed, which correspond to characteristic $^4G_{5/2} \rightarrow ^6H_{5/2}$, $^4G_{5/2} \rightarrow ^6H_{7/2}$, and $^4G_{5/2} \rightarrow ^6H_{9/2}$

Fig. 8 (a) Decay curves of Sm³⁺ ions in KGP:Sm³⁺ and KGP:Bi³⁺,Sm³⁺ phosphors by monitoring at 596 nm; and (b) decay curves of Bi³⁺ ions in KGP:Bi³⁺ and KGP:Bi³⁺,Sm³⁺ phosphors by monitoring at 445 nm.

Fig. 9 Energy level diagram of KGP:Bi³⁺,Sm³⁺ phosphors (NR stands for non-radiative transition, E.T. stands for energy transfer).

transitions of Sm³⁺ ions respectively. When Bi³⁺ is co-doped into host lattice, the band emission of Bi³⁺ ions from 330 to 650 nm appears, and the emission intensity of Sm³⁺ is enhanced. Compared with the spectrum of KGP:Bi³⁺, the co-doping of Sm³⁺ leads to the decrease of emission intensities of Bi³⁺. There might be energy transfer from Bi³⁺ ions to Sm³⁺ ions.

In order to explore the energy transfer process, the excitation spectra and decay curves were measured. Fig. 7(c) displays the excitation spectra of Sm³⁺ ions in KGP:Sm³⁺ and KGP:Bi³⁺,Sm³⁺ phosphors by monitoring at the dominant emission at 596 nm. In the spectrum of KGP:Sm³⁺, excitation peaks located at 245, 273, and 310 nm are due to the Gd³⁺ absorptions.³⁸ Meanwhile, several excitation peaks corresponding to the characteristic Sm³⁺ absorptions can also be observed, which are located at 343 nm (⁶H_{5/2} → ⁴D_{7/2}), 360 nm (⁶H_{5/2} → ⁴D_{3/2}), 373 nm (⁶H_{5/2} → ⁶P_{7/2}), 400 nm (⁶H_{5/2} → ⁶P_{3/2}), 414 nm (⁶H_{5/2} → ⁴M_{19/2}), 436 nm (⁶H_{5/2} → ⁴M_{17/2}), and 450 nm (⁶H_{5/2} → ⁴I_{11/2} + ⁴M_{15/2}).^{39,40} After co-doping with Bi³⁺, a new excitation band from 220 to 270 nm appears, which matches the excitation spectrum of Bi³⁺ ions in Fig. 4(b). Besides, the intensity of Sm³⁺ excitation peaks increases, which might due to the overlap of the emission spectrum of Bi³⁺ and excitation spectrum of Sm³⁺. In other words, co-doping with Bi³⁺ will enhance the excitation intensity of Sm³⁺. Fig. 7(d) exhibits the excitation spectra of Bi³⁺ in KGP:Bi³⁺ and KGP:Bi³⁺,Sm³⁺ phosphors by monitoring at 445 nm. Only one excitation band centered at 252 nm can be observed, and the co-doping of Sm³⁺ ions leads to the decrease of excitation intensity of Bi³⁺. Thus, we can speculate that there is energy transfer from Bi³⁺ to Sm³⁺ in KGP:Bi³⁺,Sm³⁺ phosphor. To further confirm the energy transfer process, the decay curves of Sm³⁺ and Bi³⁺ were studied. Fig. 8(a) exhibits the decay curves

Fig. 10 (a) Temperature dependent emission spectra of KGP:Bi³⁺,Sm³⁺ phosphor from 11 to 295 K under 266 nm excitation. Inset: Integral emission intensity of Bi³⁺ and Sm³⁺. of Sm³⁺ (596 nm) in KGP:Sm³⁺ and KGP:Bi³⁺,Sm³⁺ samples. A rise time can be observed in the curve of KGP:Sm³⁺, and the decay lifetime is calculated to be 3.94 ms by using the mono-exponential fitting equation:

$$I(t) = I_0 \exp(-t/\tau) \quad (8)$$

where $I(t)$ is the total intensity at time t , I_0 is intensity at $t = 0$ and τ is lifetime. After co-doping with Bi³⁺, the rise time disappears and the lifetime decreases to 2.93 ms, illustrating that Bi³⁺ ions accelerate the population of Sm³⁺ in the excited state. Fig. 8(b) exhibits the decay curves of Bi³⁺ (445 nm) in KGP:Bi³⁺ and KGP:Bi³⁺,Sm³⁺ phosphors. After co-doping with Sm³⁺, the lifetime values of Bi³⁺ decreased from 0.412 μ s to 0.394 μ s. As aforementioned, there is an energy transfer process from Bi³⁺ to Sm³⁺. The corresponding energy level diagram of KGP:Bi³⁺,Sm³⁺ sample is displayed in Fig. 9.

3.3 Temperature sensing performance

Fig. 10(a) shows the temperature dependent emission spectra of KGP:Bi³⁺,Sm³⁺ phosphor in the range of 11 to 295 K with excitation at 266 nm. The integral emission intensities of Bi³⁺ and Sm³⁺ ions are shown in the inset. As the temperature increases, the emission intensity of Bi³⁺ increases firstly and then decreases, similar to the variation in KGP:Bi³⁺ phosphor. However, the emission intensity of Sm³⁺ decreases gradually with raising temperature. Fig. 10(b) shows the temperature dependent CIE diagram of KGP:Bi³⁺,Sm³⁺ phosphor. The emission colors travel through yellow to with the temperature increases from 11 to 295 K, and the corresponding CIE coordinates are listed in Table S2.† Furthermore, the emission intensity ratio (R) of Bi³⁺ to Sm³⁺ was found to be temperature dependent and can be used for the temperature sensing. Fig. 10(c) shows the experimental data of R and the fitting curve.

Table 1 Comparison of the Sensitivities with the reported phosphors

Material	Temperature range (K)	Max S_a (% K ⁻¹)	Max S_r (% K ⁻¹)	Ref.
Ca ₂ YZr ₂ Al ₃ O ₁₂ :Bi ³⁺ ,Sm ³⁺	298–473	0.099	0.356	42
La ₃ Ta _{0.8} Sb _{0.2} O ₇ :Bi ³⁺ ,Sm ³⁺	303–523	5.9	1.32	43
Sr ₃ Y ₂ Ge ₃ O ₁₂ :Bi ³⁺ ,Sm ³⁺	298–498	0.17	0.57	44
KGP:Bi ³⁺ ,Sm ³⁺	44–182	1.57	3.135	This work
KGP:Bi ³⁺ ,Sm ³⁺	295–523	4.064	1.808	This work

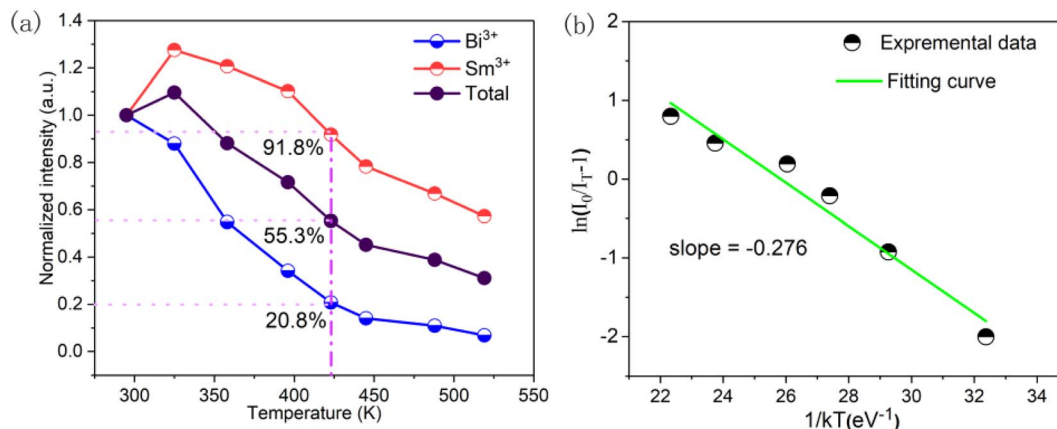

Fig. 12 (a) Normalized emission intensity of Bi^{3+} , Sm^{3+} , and total emission intensity as a relation with temperature; (b) plot of $\ln(I_0/I_T - 1)$ versus $(1/kT)$ for the calculation for the E_a of $\text{KGP}:\text{Bi}^{3+}, \text{Sm}^{3+}$ phosphor.

In the temperature range from 44 to 182 K, the data can be linearly fitted. The equation can be expressed as:

$$R = A \times T + B \quad (9)$$

where A is the slope of fitting curve, B is a constant. The parameters of A and B were determined to be 0.0157 and -0.19 , respectively. The absolute sensitivity (S_a) and relative sensitivity (S_r) can be calculated by following equations:

$$S_a = \left| \frac{dR}{dT} \right| = A \quad (10)$$

$$S_r = \left| \frac{1}{R} \frac{dR}{dT} \right| = \frac{A}{A \times T + B} \quad (11)$$

For this sample, the absolute sensitivity is $1.57\% \text{ K}^{-1}$, and the maximum relative sensitivity is $3.135\% \text{ K}^{-1}$ at 44 K, as shown in Fig. 10(d).

To further explore the temperature sensing performance above room temperature of $\text{KGP}:\text{Bi}^{3+}, \text{Sm}^{3+}$ phosphor, the emission spectra in the temperature range from 295 to 523 K were studied with excitation at 266 nm. In Fig. 11(a), the emission intensity of Bi^{3+} decreases with increasing temperature due to thermal quenching effect, while the emission intensity of Sm^{3+} increases firstly and then decreases. The increase of Sm^{3+} intensity may be due to the accelerated energy transfer caused by heating. Fig. 11(b) and Table S3† displays the CIE diagram of $\text{KGP}:\text{Bi}^{3+}, \text{Sm}^{3+}$ phosphor, in which the emission color can be turned from white to yellow with the increase of temperature.

For the application of temperature sensing, the emission intensity of Sm^{3+} can be regarded as a constant (I_C) and can be used as a self-reference. Based on the Struck and Fonger theory,⁴¹ the relationship between emission intensity and temperature can be expressed by following equation:

$$I(T) = \frac{I_0}{1 + A \exp(-\Delta E_a/kT)} \quad (12)$$

where $I(T)$ and I_0 represents the emission intensity at T and low temperature; A is a constant; ΔE_a represents the activation energy related to thermal quenching; k is the Boltzmann constant.

Based on eqn (12), the emission intensity ratio (R) of Sm^{3+} to Bi^{3+} can be expressed as:

$$\begin{aligned} R &= \frac{I_{\text{Sm}}}{I_{\text{Bi}}} = \frac{I_C}{\frac{I_{0,\text{Bi}}}{1 + A \exp(-\Delta E_{a,\text{Bi}}/kT)}} \\ &= \frac{I_C}{I_{0,\text{Bi}}} \left[1 + A_{\text{Bi}} \exp\left(-\frac{\Delta E_{a,\text{Bi}}}{kT}\right) \right] \approx B + C \exp(-\Delta E/kT) \end{aligned} \quad (13)$$

where B , C , and ΔE are parameters related to Bi^{3+} and Eu^{3+} . The corresponding absolute sensitivity S_a and relative sensitivity S_r can be expressed as:

$$S_a = \left| \frac{dR}{dT} \right| = C \exp(-\Delta E/kT) \times \frac{\Delta E}{kT^2} \quad (14)$$

$$S_r = \left| \frac{1}{R} \frac{dR}{dT} \right| = \frac{C \exp(-\Delta E/kT)}{B + C \exp(-\Delta E/kT)} \times \frac{\Delta E}{kT^2} \quad (15)$$

As shown in Fig. 11(c), the emission intensity ratio of Sm^{3+} to Bi^{3+} can be adopted for the temperature sensing. By using eqn (13), the plot can be well fitted and corresponding parameters of B , C , and $\Delta E/k$ were determined to be -0.075 , 121.17 , and 1443.75 cm^{-1} respectively. Fig. 11(d) shows the calculated sensitivities by eqn (14) and (15). The absolute sensitivity increases with temperature and reaches maximum of $4.064\% \text{ K}^{-1}$ at 523 K. By contrast, the relative sensitivity decreases with temperature and reaches the maximum of $1.808\% \text{ K}^{-1}$ at 295 K, indicating that it is a good candidate for application of optical thermometer. The sensitivities of this phosphor are comparable to the reported phosphors, as shown in Table 1.

3.4 Thermal stability

Thermal stability is an important parameter which affects the application of optical materials in LEDs. Fig. 12(a) displays the

thermal stability of KGP:Bi³⁺,Sm³⁺ phosphor. At 423 K, the emission intensities of Bi³⁺, Sm³⁺, and total emission quench to 20.8%, 91.8%, and 55.3% of its initial intensity at 295 K. Fig. 12(b) exhibits the plot of ln(I₀/I_T - 1) against (1/kT), and the calculated slope correspond to the activation energy in the thermal quenching process of KGP:Bi³⁺,Sm³⁺ phosphor, which is determined to be 0.276 eV.

4. Conclusion

In summary, a series Bi³⁺, Sm³⁺ single doped and co-doped KGP samples were successfully synthesized by high temperature solid state method. Based on the emission spectrum, excitation spectra, as well as decay curves, the energy transfer process from Gd³⁺ and Bi³⁺ to Sm³⁺ can be demonstrated. Furthermore, the tunable emission color can be obtained by co-doping Sm³⁺ with Bi³⁺. The emission intensity ratio of Bi³⁺ and Sm³⁺ was found to be temperature dependent and can be used for the optical temperature sensing in a wide temperature range. The maximum relative sensitivity of KGP:Bi³⁺,Sm³⁺ phosphor reaches 3.13% K⁻¹. Meanwhile, a high thermal stability of 55.3% at 423 K can be obtained for KGP:Bi³⁺,Sm³⁺ phosphors.
