## Introduction

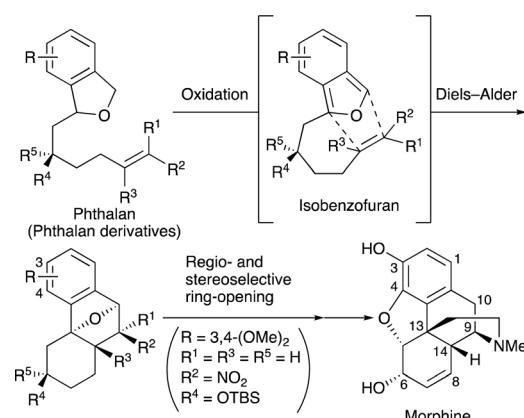

Due to the structural features and the ease of aromatization of Diels–Alder adducts under acidic conditions, isobenzofurans (IBFs) have been recognized as useful intermediates for the preparation of fused polycyclic aromatic compounds.<sup>1</sup> Despite being aromatic compounds with  $10\pi$ -electrons, IBFs are extremely reactive and prone to dimerization or polymerization in solution.<sup>2</sup> While aryl and electron-withdrawing substituents on the furanoid ring stabilize the system, less stable IBFs should be generated *in situ* and used for the following reaction without isolation.

To date, a variety of methods involving retro Diels–Alder reaction,<sup>2a,3</sup> 1,4-elimination of dihydroisobenzofuranols and their ethers,<sup>4</sup> isomerization of benzalphthalan,<sup>5</sup> enolization of phthalides,<sup>6</sup> transannular cyclization of carbenes, carbenoids, or Pummerer cations with adjacent carbonyl groups,<sup>7</sup> and electrophilic cyclization of *o*-carbonylated phenylacetylenes<sup>8</sup> have been developed to generate IBFs.<sup>9</sup> However, oxidation has never been utilized for this purpose except for a few examples,<sup>10</sup> probably due to the electron-rich nature of IBFs. With the availability of phthalan derivatives in mind,<sup>11</sup> we wondered whether IBFs could be generated from the corresponding phthalans by oxidation. Intramolecular trapping of IBFs with  $\pi$ -

bonds at a suitable position can circumvent the aforementioned stability issue, leading to the formation of benzene-fused, oxygen-bridged polycyclic compounds that would be employed for the syntheses of bioactive natural products<sup>12</sup> (Scheme 1). In this paper, we report a novel oxidation/intramolecular Diels–Alder (IMDA) strategy for the construction of an octahydrophenanthrene skeleton, the synthetic utility of which was demonstrated by the formal total synthesis of  $(\pm)$ -morphine.

## Results and discussion

At the outset of this study, we selected phthalan **1** (ref. 13) as a substrate and investigated the tandem oxidation/IMDA sequence. Although palladium catalysts can be used for

Scheme 1 Tandem oxidation/intramolecular Diels–Alder approach to octahydrophenanthrene derivatives and the structure of morphine.

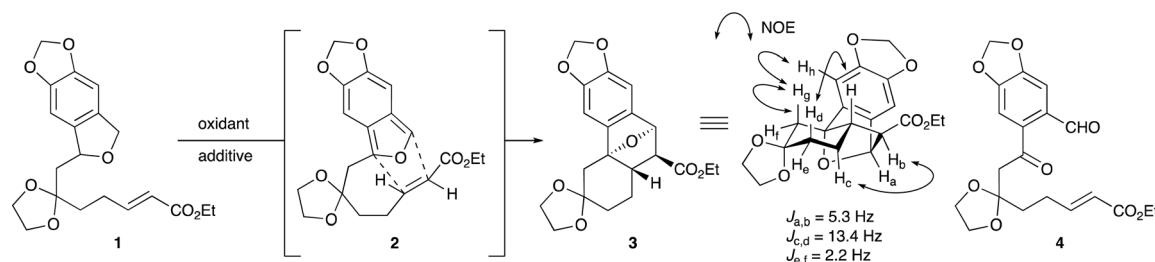

dehydrogenative aromatization reactions,<sup>14</sup> treatment of **1** with Pd/C in 2-methylnaphthalene afforded no reaction and heating at 240 °C led to partial decomposition (Table 1, entry 1). In contrast, the use of 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ)<sup>15,16</sup> as a stoichiometric oxidant in CH<sub>2</sub>Cl<sub>2</sub> at room temperature resulted in a complex mixture of products (entry 2). We then speculated that the IBF generated from **1** could not adopt the folded conformation **2** at room temperature. This hypothesis was validated by the observation that cycloadduct **3** was obtained as a single isomer in 20% yield when the reaction was performed in dodecane at 100 °C (entry 3). However, competitive overoxidation under these conditions was suggested by the formation of ketoaldehyde **4** as a byproduct. This overoxidation was suppressed by switching the oxidant from DDQ to less reactive *p*-chloranil, although the reaction was quite slow and the product yield (23%) was comparable at this temperature due to the 40% recovery of **1** after a prolonged reaction time (10 h, entry 4). An examination of the temperature profile of the reaction revealed that the product yield was improved to 65% by raising the temperature to 180 °C, but the reaction at a higher temperature (200 °C) afforded no discernible benefits (entries 4–6). A significant solvent effect exists in this transformation; dodecane proved to be the solvent of choice for this transformation, whereas the reaction in *o*-dichlorobenzene shortened the reaction time (entries 5 vs. 7, 8). While the addition of 2,6-di-*tert*-butyl-4-methylphenol (BHT) as a radical scavenger resulted in a low yield, we were gratified to find a beneficial effect of molecular sieves (MS),<sup>17</sup> providing cycloadduct **3** in 91% yield by the use of 3 Å MS (entries 9–12). It

should be mentioned that naphthalene derivatives arising from aromatization were not detected under these conditions. The stereochemical assignment for cycloadduct **3** was determined by the diagnostic <sup>1</sup>H NOE correlation between H<sub>g</sub> and H<sub>h</sub>.<sup>18</sup>

Having optimized the reaction conditions, the scope of the tandem oxidation/IMDA sequence was explored (Scheme 2). As expected, reactions of phthalans having trisubstituted or nitro-substituted olefins gave the corresponding endo cycloadducts **5** and **6** in good yields. It is noteworthy that chemoselective oxidation could be attained under these conditions, leaving the formyl group intact, albeit in modest yield of aldehyde **7** (54%). The electron-withdrawing substituent on the olefin was found to be unnecessary, but the tandem reaction of phthalan **8a** was accompanied by aromatization of the 11-oxatricyclo[6.2.1.0<sup>1,6</sup>]undecane moiety, giving naphthalene and phenanthrene derivatives **16** and **17** as byproducts in 19% and 7% yields, respectively. A quaternary stereocenter could be created by using 1,1-disubstituted alkenes **9a** and **10a** as substrates: even the alkene bearing an electron-donating methyl group gave cycloadduct **10**, albeit in 15% yield, whereas the hetero atom-substituted alkene in phthalan **11a** did not undergo cycloaddition in accord with the general trend, resulting in decomposition. The tetrasubstituted alkene in phthalan **12a** could also serve as a dienophile for the sequential reaction, allowing for the simultaneous construction of three contiguous quaternary stereocenters.<sup>19</sup> Although Kanematsu and co-workers reported that IMDA reaction of an IBF lacking substitution on the tether met with failure due to rapid decomposition of the IBF,<sup>20</sup> unsubstituted product **13** was obtained according to this

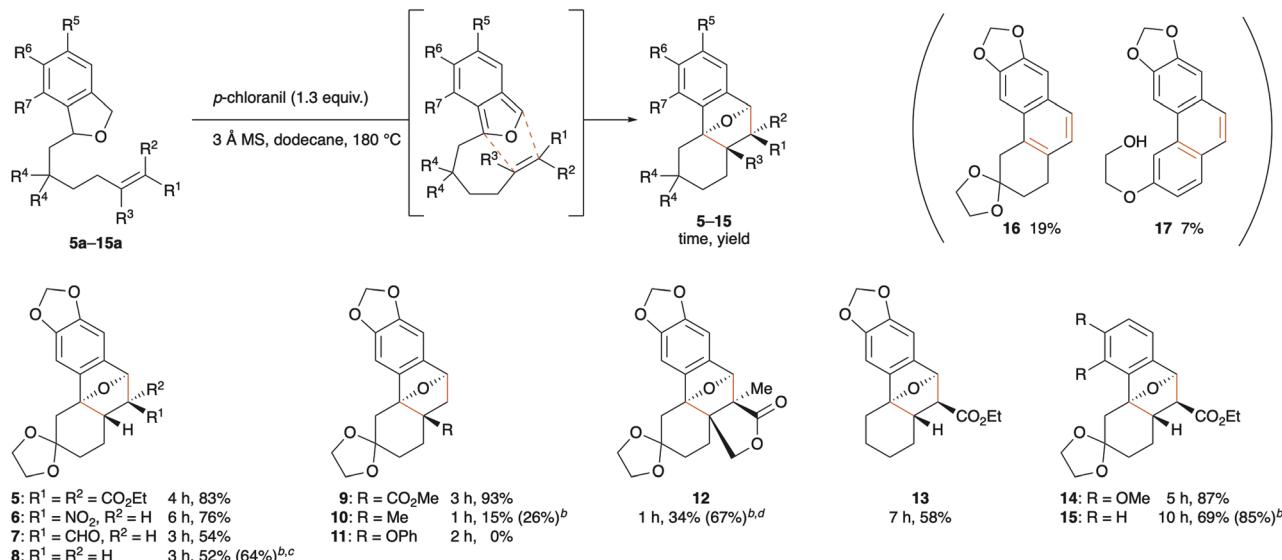

Table 1 Oxidation/IMDA sequence using phthalan **1**<sup>a</sup>

<sup>a</sup> All reactions were carried out on a 0.13 mmol scale with 1.3 equivalents of the oxidant at a concentration of 0.01 M. <sup>b</sup> TLC analysis indicated that unreacted starting material remained. <sup>c</sup> The formation of overoxidation product **4** was observed.

**Scheme 2** Substrate scope.<sup>a</sup> <sup>a</sup> All reactions were carried out on a 0.13 mmol scale with 1.3 equivalents of the oxidant at a concentration of 0.01 M. <sup>b</sup> Yields in parentheses are based on recovered starting material. <sup>c</sup> Naphthalene and phenanthrene derivatives **16** and **17** were obtained as byproducts in 19% and 7% yields, respectively. <sup>d</sup> At a concentration of 1 mM.

protocol. With regard to substituents on the benzene ring, an *ortho*-methoxy group in phthalan **14a** did not reduce the product yield, and this transformation could be applicable even to the unsubstituted substrate **15a**.

The scope of the present method is not limited to the use of alkene dienophiles (Scheme 3). The reaction of alkyne **18** furnished conjugated ester **19** (67% yield), the alkene moiety of which can be used as a handle for further functionalization.

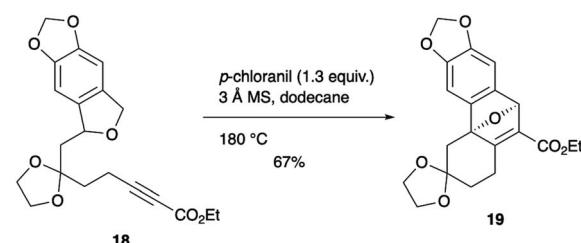

To demonstrate the synthetic utility of our method, we then addressed the formal synthesis of ( $\pm$ )-morphine. Due to their important pharmacological properties and strained pentacyclic structure, morphine and related natural products have been recognized as attractive targets of synthetic interest, and many groups have made impressive contributions to the literature on the syntheses of these molecules.<sup>21-54</sup>

The synthesis was initiated with the sequential Heck/oxa-Michael reaction between iodide **20** (ref. 55) and enone **21** (ref. 56) in the presence of Ag<sub>3</sub>PO<sub>4</sub> (ref. 59) in *N,N*-dimethylformamide (DMF) at 110 °C, affording phthalan **22** in 82% yield (Scheme 4). The carbonyl group was reduced with Li(s-Bu)<sub>3</sub>BH in THF at -78 °C,<sup>60,61</sup> and the resultant alkoxide was

protonated and silylated *in situ*<sup>62</sup> to give *tert*-butyldimethylsilyl (TBS) ether **23** as an inseparable 15 : 1 mixture of diastereomers in 85% yield. After reduction of the Weinreb amide with *i*-Bu<sub>2</sub>AlH in CH<sub>2</sub>Cl<sub>2</sub> at -78 °C, one-pot homologation of aldehyde **24** to nitroalkene **25** under Merck conditions<sup>63</sup> set the stage for the key oxidation/IMDA sequence.

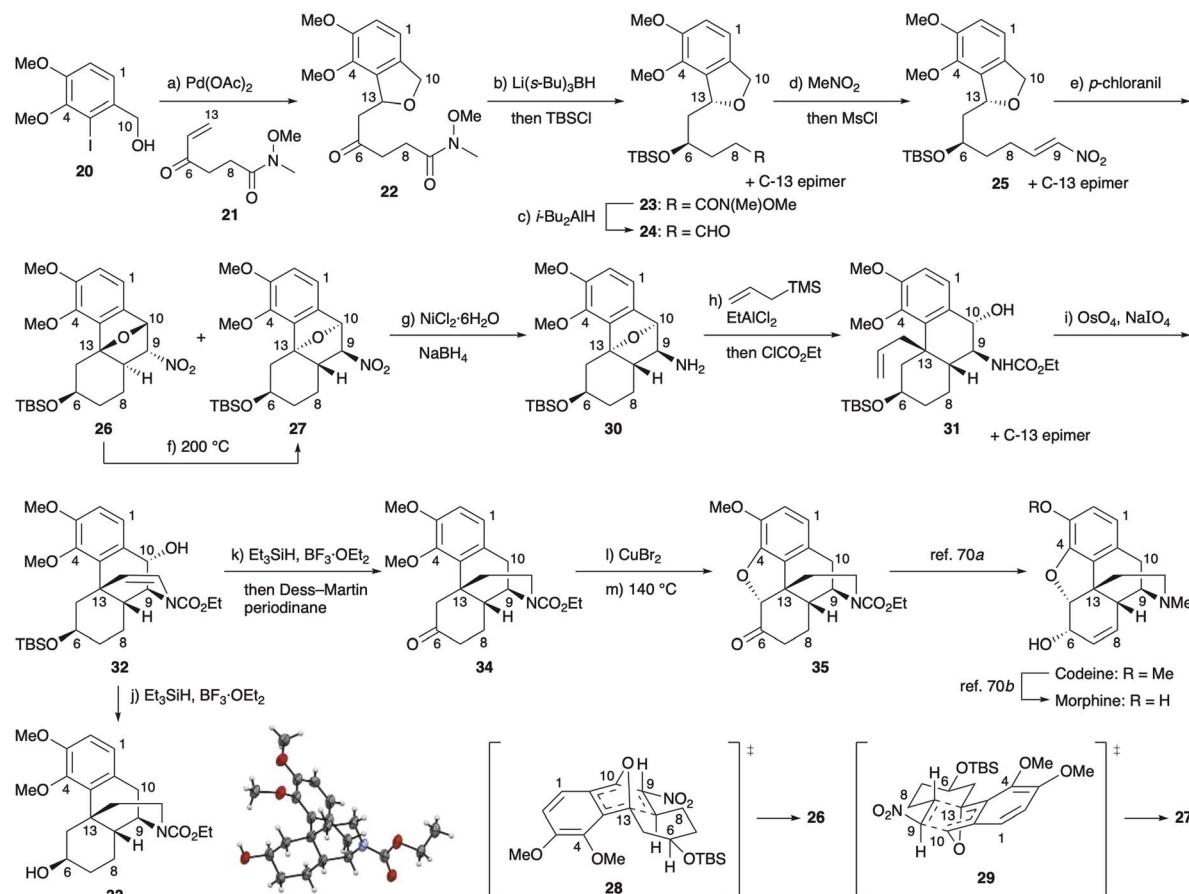

We expected that stereoinduction would be observed when using phthalans with a stereocenter in the tether as substrates. As anticipated, a 1 : 2.7 mixture of cycloadducts **26** and **27** was obtained in 81% yield upon heating at 200 °C for 3 h. Transition state **29**, in which the cyclohexane ring adopts a chair conformation, is favoured over the diastereomeric transition state **28**, thus leading to the preferential formation of **27**.<sup>64</sup> At this juncture, we noticed that independent submission of cycloadducts **26** and **27** to BHT in dodecane at 200 °C provided identical ratios of isomers (**26** : **27** = 1 : 3.6).<sup>65</sup> While the reactions of IBFs were reported not to be reversible under the conditions normally employed,<sup>1b,66</sup> our results clearly revealed that the cycloaddition was reversible. Although both stereoisomers **26** and **27** could be carried forward, it was more expedient to work with a homogeneous material. We then proceeded forward in the synthesis with major isomer **27**.

Given characteristic oxygen-bridged products obtained by the present oxidation/IMDA reactions, regio- and stereoselective ring-opening methods need to be devised for the application to total synthesis. After considerable experimentation with regard to the ring-opening of **27**, reaction of amine **30**, obtained by reduction of **27** using NiCl<sub>2</sub>/NaBH<sub>4</sub> in MeOH in 82% yield,<sup>67</sup> with allyltrimethylsilane with the aid of EtAlCl<sub>2</sub> in CH<sub>2</sub>Cl<sub>2</sub> at -45 °C was found to fulfill this requirement, providing a 2 : 1 mixture of allylation products **31** and 13-*epi*-**31** in 57% yield after *N*-protection with ClCO<sub>2</sub>Et.<sup>68</sup> Oxidative cleavage of the olefin in allylation product **31** with OsO<sub>4</sub>/NaIO<sub>4</sub> (ref. 69) was

**Scheme 3** Tandem oxidation/intramolecular Diels–Alder reaction of ynoate **18**.

NaOH, 14 h, 31 38%, 13-*epi*-31 19%; (i) OsO<sub>4</sub> (2 mol%), NaIO<sub>4</sub> (4 equiv.), 2,6-lutidine (2 equiv.), 3 : 1 1,4-dioxane/H<sub>2</sub>O, 36 h, 77%; (j) Et<sub>3</sub>SiH (3 equiv.), BF<sub>3</sub> · OEt<sub>2</sub> (2.5 equiv.), CH<sub>2</sub>Cl<sub>2</sub>, -78 to 0 °C, 2.5 h, 70%; (k) Et<sub>3</sub>SiH (3 equiv.), BF<sub>3</sub> · OEt<sub>2</sub> (3 equiv.), CH<sub>2</sub>Cl<sub>2</sub>, -78 to 0 °C, 2 h, then Dess–Martin periodinane (2 equiv.), pyridine (2.5 equiv.), 1 h, 73%; (l) CuBr<sub>2</sub> (2.2 equiv.), 1 : 1 CHCl<sub>3</sub>/AcOEt, 70 °C, 2 h; (m) DMF, 140 °C, 25.5 h, 42% (59% after two cycles). Ms = methanesulfonyl; TMS = trimethylsilyl.

accompanied by cyclization to furnish enecarbamate 32 in 77% yield. The benzylic hydroxy group and double bond were successfully reduced upon treatment of enecarbamate 32 with  $\text{Et}_3\text{SiH}$  in the presence of  $\text{BF}_3 \cdot \text{OEt}_2$  in  $\text{CH}_2\text{Cl}_2$  at  $-78^\circ\text{C}$ , and raising the temperature to  $0^\circ\text{C}$  effected desilylation, affording crystalline alcohol 33, the stereochemistry of which was unambiguously established by X-ray crystallography.<sup>70</sup> Ene-carbamate 32 could be converted to ketone 34 by a one-pot procedure involving oxidation of alcohol 33 with Dess–Martin periodinane<sup>57</sup> buffered with pyridine. Ketone 34 underwent  $\alpha$ -bromination with  $\text{CuBr}_2$  in refluxing  $\text{CHCl}_3/\text{AcOEt}$ ,<sup>46,71</sup> and heating the crude product in DMF at  $140^\circ\text{C}$  effected intramolecular etherification to provide *N*-carbethoxynorcodeinone (35)<sup>72a</sup> in 59% yield after one recycle.<sup>73</sup> While the conversion of 35 to codeine<sup>72a</sup> and its *O*-demethylation to morphine<sup>72b</sup> were reported by the Rice group, the synthesis of 35 constitutes a formal synthesis of  $(\pm)$ -morphine.

## Conclusions

We have developed a novel oxidation/IMDA reaction sequence, wherein unstabilized IBFs were generated as transient species from phthalans upon oxidation with *p*-chloranil. Exclusive formation of endo cycloadducts was observed and the reaction proved to be reversible under these conditions. This metal-free protocol represents the first general method for oxidative generation of IBFs and the first example that provides experimental evidence for the reversibility of Diels–Alder reactions of IBFs without using maleic anhydride as a dienophile. The method presented herein offers the advantage of obtaining cycloadducts without aromatization in most cases, and the bridging oxygen can serve as a handle for the installation of substituents at the benzylic position. The successful application to the formal synthesis of ( $\pm$ )-morphine attests to the power of the present method in natural product synthesis.

## Data availability

The data supporting this article have been included as part of the ESI. Crystallographic data for compound 33 have been deposited at the Cambridge Crystallographic Data Center (CCDC) under CCDC 2237321.‡

## Author contributions

S. N. conceived the project and prepared the manuscript. S. N. and H. Y. designed the project and directed the investigations. M. K., H. Y., Ma. T., E. O., K. N., T. W., M. U., Mi. T. and S. N. performed the experiments. H. Y., Ma. T., E. O., K. N., T. W., K. I. and S. N. prepared the ESI. All of the authors discussed the results.

59 The addition of  $\text{Ag}_3\text{PO}_4$  proved to be crucial for the reaction to proceed to completion. For the use of silver salt as an additive in the Heck reaction, see: (a) K. Karabelas, C. Westerlund and A. Hallberg, *J. Org. Chem.*, 1985, **50**, 3896; (b) M. M. Abelman, T. Oh and L. E. Overman, *J. Org. Chem.*, 1987, **52**, 4130.

60 To work with a homogeneous material, the carbonyl group was reduced in a stereoselective manner according to the report by Carter and Mahapatra. The relative stereochemistry at C-13 of the major isomer was tentatively assigned on the basis of their report. S. Mahapatra and R. G. Carter, *J. Am. Chem. Soc.*, 2013, **135**, 10792.

61 While not examined, the use of asymmetric reduction can lead to the synthesis of optically active morphine.

64 Following a referee's suggestion, we performed calculations using the Gaussian package (see Section 4 in ESI†). However, calculations employing B3LYP/6-31G\* level of theory indicate that transition state **29** is estimated to be 2.9 kcal mol<sup>-1</sup> lower in energy than transition state **28**. Further efforts to account for the moderate stereoselectivity by more rigid computational analysis are in progress.

65 When heated in dodecane at 200 °C in the absence of BHT, cycloadducts **26** and **27** completely decomposed before reaching equilibrium, suggesting that BHT served to protect the cycloadducts from decomposition through retro Diels–Alder reaction. In the tandem oxidation/IMDA sequence, BHT was speculated to interfere with the oxidation of phthalans by *p*-chloranil, leading to the decrease in chemical yield.

66 Cycloadditions with maleic anhydride were found to be reversible in some cases. (a) Ref. 4b; (b) J. P. McCormick and T. Shinmyozu, *J. Org. Chem.*, 1982, **47**, 4011.

73 Rice and co-workers only reported characteristic NMR signals of intermediate **35**,<sup>72a</sup> and signals derived from rotamers were not mentioned, although the use of variable-temperature NMR methods was not explicitly stated. We therefore confirmed that <sup>1</sup>H NMR spectrum of intermediate **35** measured in pyridine-*d*<sub>5</sub> was in close agreement with that reported for the corresponding methyl carbamate by Opatz and co-workers.<sup>46</sup>
