# Direct synthesis of *N*-perfluoro-*tert*-butyl secondary amines from *N*-trifluoromethyl secondary amines†

Leibing Wang,<sup>a</sup> Zhongyu Feng,<sup>a</sup> Zhen Luo,<sup>a</sup> Zihao Guo,<sup>a</sup> Jieping Wang<sup>\*a</sup> and Wenbin Yi<sup>\*ab</sup>

*N*-Perfluoro-*tert*-butyl (*N*-PF<sub>t</sub>B) secondary amines, harboring a unique <sup>19</sup>F-reporting moiety linked directly to nitrogen, are highly attractive due to their diverse potential applications. However, their mild and facile synthesis remains a significant challenge. Herein, we present a safe and efficient strategy for the direct synthesis of *N*-perfluoro-*tert*-butyl secondary amines from readily available *N*-trifluoromethyl secondary amines. Experiments and theoretical calculations demonstrate that this novel protocol encompasses three main processes: the elimination of hydrogen fluoride from the *N*-trifluoromethyl precursor, consecutive addition–elimination conversion of difluoromethyl imine (R–N=C(F)<sub>2</sub>) to hexafluoropropyl imine (R–N=C(CF<sub>3</sub>)<sub>2</sub>), and final addition of R–N=C(CF<sub>3</sub>)<sub>2</sub> with the *in situ* generated fluoroform (HCF<sub>3</sub>). Key advantages of this reaction include the utilization of a single trifluoromethyl source and the *N*-trifluoromethyl starting material itself as the hydrogen source. Notably, the elimination of hydrogen fluoride, facilitated by CsF, is critical for the success of this approach. This method is compatible with a broad range of functional groups, including heterocyclic compounds. <sup>19</sup>F MRI experiments suggest promising prospects for PF<sub>t</sub>B-labeled secondary amines as <sup>19</sup>F MRI contrast agents.

## Introduction

Fluorine chemistry has seen significant advancements in recent years, with applications emerging in biomedicine<sup>1,2</sup> and materials science.<sup>3,4</sup> Synthetic methods for mono-, di-, and trifluoromethylation are now well-established and highly sophisticated.<sup>5</sup> Alongside these developments, short-chain perfluoroalkylation methodologies have garnered increasing attention due to the unique properties of perfluoroalkyl-containing compounds,<sup>6–10</sup> which hold considerable promise in therapeutic and diagnostic applications.<sup>11–13</sup> Perfluoro-*tert*-butyl (PF<sub>t</sub>B) is particularly valuable in this context, playing a crucial role in <sup>19</sup>F-labeled NMR<sup>9,14</sup> and MRI probes,<sup>15–17</sup> as well as <sup>19</sup>F MRI contrast agents.<sup>18,19</sup> PF<sub>t</sub>B offers a distinct and singular <sup>19</sup>F signal, providing significant advantages in imaging. Not only does <sup>19</sup>F sensitivity rival that of <sup>1</sup>H, but its signal originates solely from the imaging agent, eliminating interference from background signals. Evidently, the growing

demand for perfluorinated compounds in these fields underscores the importance of methodological studies for PF<sub>t</sub>B group synthesis.

Given the ubiquitous role of nitrogen in drug molecules, compounds combining nitrogen with the PF<sub>t</sub>B group, particularly *N*-PF<sub>t</sub>B secondary amines, are highly attractive and hold significant promise. However, the lack of a general synthesis method has resulted in limited reports of such compounds to date. The existing route developed by Petrov involves obtaining R–NHC(CF<sub>3</sub>)<sub>3</sub> from the hexafluoropropyl imine intermediate (R–N=C(CF<sub>3</sub>)<sub>2</sub>) following addition and hydrochloric acid treatment.<sup>20</sup> This intermediate is typically derived from conventional reactions involving gaseous hexafluoroacetone with aromatic primary amines or isocyanates (Fig. 1A).<sup>21,22</sup> However, these procedures suffer from some drawbacks, including the use of highly toxic gases, multiple steps, and demanding operations,<sup>23–25</sup> which significantly hinder the exploration and application of these compounds. Therefore, overcoming these challenges and developing a general strategy for the safe and efficient construction of *N*-PF<sub>t</sub>B secondary amines is critical.

To the best of our knowledge, the conversion from difluoromethyl imine (R–N=C(F)<sub>2</sub>) to hexafluoropropyl imine (R–N=C(CF<sub>3</sub>)<sub>2</sub>) remains unreported. We propose this conversion as a significantly safer and more efficient approach for constructing multi-CF<sub>3</sub> amines, eliminating the need for highly toxic gases. Our strategy leverages a readily available *N*-CF<sub>3</sub> secondary

A Typical methods for the synthesis of *N*-perfluoro-*tert*-butyl secondary amines

## B This work

Fig. 1 Previous work and reaction design. (A) Traditional approaches to synthesizing *N*-PFtB secondary amines; (B) our designed strategy for the construction of *N*-PFtB secondary amines.

amine as the starting material.<sup>26</sup> This amine undergoes elimination of HF to generate the highly reactive difluoromethyl imine. Subsequently, in the presence of a  $\text{CF}_3$  source, this imine undergoes two consecutive addition–elimination processes to form hexafluoropropyl imine. Finally, the target *N*-PFtB secondary amine is obtained through the addition reaction of hexafluoropropyl imine with trifluoromethyl and hydrogen (Fig. 1B). Experimental and theoretical calculations support the notion that the eliminated HF reacts further with  $\text{TMSCF}_3$ , *in situ* producing  $\text{HCF}_3$  which subsequently participates in the addition reaction with hexafluoropropyl imine. The key advantages of this novel strategy lie in its reliance on a single  $\text{CF}_3$  source and the starting material *N*- $\text{CF}_3$  secondary amine as the hydrogen source, enabling a one-step reaction under mild conditions.

## Results and discussion

To evaluate the proposed reaction pathway, we employed 4-cyanophenyl *N*-trifluoromethyl secondary amine as a model substrate. The substrate was treated with 8.0 equivalents of  $\text{TMSCF}_3$  and 1.0 equivalent of KF initiator in THF at room temperature for 6 hours. The desired product (compound **1**) was isolated in a 33% yield (Table 1, entry 1). Subsequent attempts to improve the yield by individually or concurrently increasing the amounts of  $\text{TMSCF}_3$  or KF resulted in only modest improvement. Similarly, the addition of CuCl exhibited a negligible effect on the yield (entries 2–6). Notably, the absence of KF or its substitution with NaF or TBAF (tetrabutylammonium fluoride) completely ablated product formation (entries 7–9). Further investigation revealed that cesium fluoride (CsF) was crucial for this reaction system. When 8.0 equivalents of  $\text{TMSCF}_3$  were combined with 1.0 equivalent of CsF in the presence of the substrate, the yield remarkably increased to 65% (entry 10). Employing 1.5 equivalents of CsF led to a further enhancement in product yield (entry 11). However, increasing the CsF amount to 3.0 equivalents resulted in an inhibitory effect (increase in unknown by-products, entry 12). Likewise,

Table 1 Survey of reaction conditions<sup>a</sup>

<sup>a</sup> Reaction conditions: *N*- $\text{CF}_3$  secondary amine (0.8 mmol, 1.0 equiv.), solvent (4.0 mL). <sup>b</sup> Isolated yields.

decreasing the CsF quantity to 0.5 equivalents yielded a slightly lower product formation (generation of a dimer, entry 13) (see ESI, p. S4†). These observations collectively suggest that the liberated  $\text{F}^-$  anion, after being displaced by  $\text{CF}_3^-$  during the reaction, participates again by reacting with  $\text{TMSCF}_3$  to release another  $\text{CF}_3^-$ . Among the tested solvents, THF provided the most favorable outcome (entries 14–15). Finally, the optimal reaction conditions were established by finetuning the ratio of  $\text{TMSCF}_3$  and CsF (entry 16).

To elucidate the reaction mechanism, we initially employed the *N*- $\text{CH}_3$  analog of the starting substrate under standard conditions (Fig. 2A). This experiment aimed to preliminarily

Fig. 2 Preliminary mechanistic investigations.

Table 2 Scope of *N*-perfluoro-*tert*-butyl secondary amines<sup>a</sup>

<sup>a</sup> Reaction conditions: *N*-CF<sub>3</sub> secondary amine (0.8 mmol, 1.0 equiv.), TMSCF<sub>3</sub> (4.8 mmol, 6.0 equiv.), CsF (1.2 mmol, 1.5 equiv.), THF (4.0 mL), r.t., 6 h. Isolated yields are given. <sup>b</sup> Determined by <sup>19</sup>F NMR spectroscopy using trifluoromethoxybenzene as an internal standard. <sup>c</sup> Yield of two steps.

Conversely, electron-rich aromatic rings exhibited lower tolerance. Substrates with *tert*-butyl (5), methoxy (6, 7), methyl (8), and isopropyl (9) groups afforded *N*-PF<sub>t</sub>B secondary amines in lower to moderate yields. Unexpectedly, the *ortho*-ethoxy-substituted compound (10) produced the resulting product in a 61% yield. The naphthalene ring was also compatible, although  $\alpha$ -naphthalene (12) displayed lower reactivity compared to  $\beta$ -naphthalene (13), while tetrahydronaphthalene (14) showed reactivity akin to that of  $\alpha$ -naphthalene, possibly due to steric hindrance from the PF<sub>t</sub>B group. Notably, the presence of fluorine (15), chlorine (16), bromine (17), and iodine (18) substituents on the benzene ring did not affect the reaction. These halogens remained intact, as confirmed by the absence of additional trifluoromethyl signals in GC-MS and <sup>19</sup>F NMR spectra. This compatibility is advantageous for downstream derivatization reactions. It's important to note that highly fluorinated molecules have a nonpolar character and an extremely low polarizability, inducing only weak intra- and intermolecular interactions.<sup>28</sup> Consequently, substrates 2 and 15, which contain fluorine and trifluoromethyl groups on the

benzene ring, exhibit lower boiling points compared to the other substrates, making it difficult to isolate compounds 2 and 15 under reduced pressure for extended periods. Moderate yields were obtained for ketone substrates (20, 21) and the sulfone substrate (22). Perfluoro-*tert*-butylation of thiophene (23) and protected nitrogen compounds (24, 25) also proceeded successfully. However, pyridine and thiazole starting materials did not convert to PF<sub>t</sub>B amines under standard conditions, potentially due to the instability of their *N*-CF<sub>3</sub> secondary amine precursors in the solvent-free environment. Optimized conditions were developed for a one-pot conversion of isothiocyanates to *N*-PF<sub>t</sub>B pyridine derivatives (27, 28) in THF (details in ESI, p. S27<sup>†</sup>). Similarly, trifluoromethylated thiazole (29) and isoquinoline (30) precursors, synthesized in MeCN but THF instead of Et<sub>2</sub>O in the purification procedure, were successfully transformed to corresponding compounds. The synthesis of bis-NHC(CF<sub>3</sub>)<sub>3</sub>-substituted substrates (31–33) yielded low product quantities. Notably, the standard protocol is not suitable for aliphatic substrates. The structure of *N*-PF<sub>t</sub>B secondary amine 11 was confirmed by X-ray crystallographic

Table 3 Late-stage applications<sup>a</sup>

<sup>a</sup> Derivatization and applications of *N*-PF<sub>t</sub>B secondary amines. (A) Synthesis of drug-like molecules (for details, see ESI). (B) Amine (0.3 mmol, 1.0 equiv.), iodide (5.0 equiv.), NaH (10.0 equiv.), THF, r.t., 12 h. (C) MR imaging of <sup>19</sup>F at ultra-high field.

analysis. Compound **1** exhibited stability under acidic (aqueous HCl, pH 0, 36 hours) conditions, with no degradation observed by <sup>1</sup>H NMR (phenyl region). However, minimal decomposition was detected under basic conditions (aqueous NaOH, pH 14, 36 hours) (details in ESI, p. S42<sup>†</sup>). The predicted Log *P* value of compound **1** (Log *P* = 4.85) is significantly higher than its *N*-*tert*-butyl counterpart (Log *P* = 2.27), indicating a substantial increase in lipophilicity due to the CF<sub>3</sub> groups.<sup>29</sup>

To assess the utility of this method for incorporating PF<sub>t</sub>B groups into drug-like molecules, we targeted ibuprofen (antipyretic/analgesic) and probenecid (antigout). Since *N*-CF<sub>3</sub> secondary amines bearing an unprotected NH<sub>2</sub> group were not accessible using our previously reported method,<sup>26</sup> it is more feasible to obtain such an active precursor (**34**) by reducing a NO<sub>2</sub> group containing *N*-PF<sub>t</sub>B secondary amine (**3**). Following the reduction of compound **3** and subsequent condensation, the PF<sub>t</sub>B group was successfully introduced into these drugs with excellent yields (ibuprofen: **36**, 97%; probenecid: **37**, 81%). Notably, the PF<sub>t</sub>B group remained intact during ester deprotection. Furthermore, *N*-PF<sub>t</sub>B derivatives of procaine (local anesthetic, **38**) and prucalopride (constipation treatment, **39**) were obtained *via* smooth condensation with the amino or hydroxyl groups (Table 3A). These examples demonstrate the compatibility of *N*-PF<sub>t</sub>B secondary amines with various derivatization reactions. Capitalizing on the stability of the N–H bond, we achieved *N*-methylation under strong basic conditions (NaH) using multiple substrates. Naphthalene (**41**), cyano (**40**), benzyl (**42**), ester (**43**), halogen (**44**, **45**), and Boc-protected amino (**46**)

substituted *N*-PF<sub>t</sub>B amines yielded the corresponding methylated products in high yields. Interestingly, allyl iodide reacted with compounds **1** and **4** to afford products **47** and **48** (Table 3B), while iodoethane, iodopropane, and iodobutane were unreactive. Additionally, the acylation (**49**) reaction of N–H bond in *N*-PF<sub>t</sub>B secondary amine was successfully performed. Finally, we explored the potential of PF<sub>t</sub>B-labeled molecules for <sup>19</sup>F MRI applications using compound **36**. Compared to negative (H<sub>2</sub>O) and positive (CF<sub>4</sub>) controls, compound **36** exhibited clear imaging sensitivity at various concentrations (25, 50, 75, 100, and 125 mM). Notably, a concentration of 75 mM displayed a high level of discrimination (Table 3C). These findings suggest promising prospects for PF<sub>t</sub>B-labeled secondary amines as <sup>19</sup>F MRI contrast agents.

## Conclusions

In summary, this study describes a novel and efficient one-step method for the synthesis of aromatic *N*-PF<sub>t</sub>B secondary amines from readily available *N*-CF<sub>3</sub> secondary amine precursors. The reaction involves the strategic elimination of HF from starting materials, rapid conversion of C–F bonds to C–CF<sub>3</sub> groups, and incorporation of the *in situ* generated fluoroform. This method is compatible with a broad range of functional groups, including complex compounds. Experimental results and DFT calculations confirm the involvement of intermediates in the reaction process. This approach not only offers new insights into the reactivity of *N*-CF<sub>3</sub> secondary amines but also provides

a valuable pathway for the development of *N*-PFTB-containing drugs, imaging probes, and contrast agents.
