Synthesis and characterization of a rhodamine derivative as a selective switch-on fluorescent sensor for Cu^{2+} ions in aqueous PBS buffer and living cells[†]

Maheshkumar Prajapati,^a Nidhi Pandey,^b Sarita Kalla,^c Sateesh Bandaru^{*d} and Areti Sivaiah  ^{*a}

A novel rhodamine-based receptor molecule (L_1) was synthesized via the reaction between rhodamine hydrazide and acetylacetone. Several spectroscopic methods, *viz.*, FTIR spectroscopy, ^1H NMR and ^{13}C NMR, and ESI-MS, were used to characterize the receptor molecule (L_1). The L_1 demonstrated turn-on response towards Cu^{2+} ions out of 18 different metal ions studied in an aqueous buffer at pH 7.4 with a minimum detection limit of 3.58×10^{-8} M. The binding interaction between L_1 and Cu^{2+} ions was shown by absorbance studies, wherein isosbestic points were observed at 286 and 329 nm. Job's plots indicate the formation of a 1:1 complex between L_1 and Cu^{2+} ions. Additionally, DFT simulations show a strong interaction between the Cu^{2+} ions and the receptor L_1 , and TD-DFT investigations show an optical absorption shift in favor of a longer wavelength in the $\{\text{L}_1 + \text{Cu}^{2+}\}$ complex. Further, the biological applicability of L_1 for the *in vitro* detection of Cu^{2+} ions in L929 and HeLa living cells was demonstrated. These findings illustrated that L_1 could be used to detect Cu^{2+} ions in environmental and biologically relevant media.

Introduction

Copper is one of the most prominent transition-metal ions present in biological systems owing to its diverse functions.^{1–5} Copper is the third most common necessary transition-metal nutrient in the human body, after zinc and iron. The Cu^{2+} ion is a prerequisite for the synthesis of hemoglobin, and it acts as an indispensable cofactor for several metalloenzymes, including superoxide dismutase, tyrosinase, and cytochrome oxidase.^{6–10} Some of these processes are controlled by the copper concentration in a particular species. Therefore, the presence of Cu^{2+} ions in human tissue at its optimal concentration is crucial for a healthy life. If it is present,

either at low or high concentrations in human tissue, it would result in deficiency syndromes and toxicity, respectively. This can cause a series of diseases such as Menkes disease, Alzheimer's disease, anemia, myelodysplasia, and leukopenia.^{11–17} Thus, considering the deleterious effect of high levels of Cu^{2+} , the United States Environmental Protection Agency (EPA) prescribed 20 μM as the maximum contaminant level of Cu^{2+} in drinking water.¹⁸ Inductively coupled plasma-mass spectrometry (ICP-MS), atomic absorbance, colorimetry, flow injection, and electrochemical approaches are some of the current methods used for the measurement of Cu^{2+} ions.^{19–24} However, these methods are expensive, not readily available, and require highly specialized personnel. Therefore, the development of small-molecular fluorescent probes with high sensitivity and selective sensing of Cu^{2+} remain an important area of research.

A chemosensor is a molecule that enables the conversion of an analyte's information into a detectable signal, which may appear as a visible colour change or fluorescence signal changes. Thus, considerable attention has been dedicated to develop chemosensors that offer effective sensing capabilities and precise detection of substances,^{25,26} including high sensitivity and selectivity, ease of operation, and quick response. Therefore, the fluorescent sensor approach has emerged as a practical and prominent method for metal ion

detection.^{27,28} Hence, there is always a dire need to design and develop small-molecular receptors that can detect and image Cu²⁺ selectively using relatively easier techniques such as absorbance and fluorescence.²⁹⁻³³ In the past few decades, a variety of organic molecules such as rhodamine, coumarin-benzopyrylium, benzothiadiazole, anthracene, phenothiazine, and squaraine have been synthesized and are being studied as possible chemosensors that can detect a variety of metal ions.³⁴⁻³⁹ However, high detection limits, significant interference from other ions and lower wavelengths of excitation and emission when detecting Cu²⁺ are only a few of the drawbacks of several fluorescent molecular probes reported in the literature.

Among several fluorescent probes, rhodamine is used as one of the most promising fluorophore moieties for developing fluorescence sensors for ions and molecules. This is attributed to its unique features including longer excitation and emission wavelengths, high quantum yields, high photostability, and easy functionalization. Additionally, rhodamine conjugates exhibit a visual color change in the presence of analytes, enabling naked-eye detection.⁴⁰⁻⁴³ Furthermore, the fluorescence emission properties of rhodamine conjugates can be tuned by controlling their derivatization with appropriate molecules. These modified rhodamine derivatives have the potential to alter the selectivity and sensitivity of various analytes. As a result, rhodamine-based fluorescent probes have emerged as promising optical sensors due to their exceptional characteristics, which encompass both physicochemical and optical properties.⁴⁴⁻⁴⁷

The search for new receptor molecules that have excellent selectivity and can detect Cu²⁺ ions at very low concentrations remains an active and difficult task for synthetic chemists. Another challenging factor for synthetic chemists is the solubility of the receptor molecule in biological media. The fluorescence receptor reported in this study is capable of detecting copper at nanomolar levels in aqueous solutions. Rhodamine is used as the skeleton to make the derivative have longer excitation and emission wavelengths, high photostability, and easy functionalization. In addition, rhodamine conjugates display a visual color change in the presence of analytes, which provides an opportunity for naked-eye detection. Therefore, in this study, we synthesized and characterized a rhodamine-based receptor linked through an acetylacetone moiety. The selective recognition of L₁ towards Cu²⁺ ions in the presence of several other metal ions in aqueous solutions was studied by absorption and fluorescence spectroscopy. The 1:1 {L₁ + Cu²⁺} complex coordination was supported by a DFT computational study. The potential applicability of L₁ in detecting Cu²⁺ ions was demonstrated in living cells.

Experimental section

Materials and methods

A Bruker NMR spectrometer was used to record the ¹H and ¹³C NMR spectra, running at frequencies of 600 MHz and

100 MHz, respectively. Using Q-TOF micro mass (YA-105) equipment by the electrospray ionization method, ESI-MS analysis was carried out. A Carry Eclipse fluorescence spectrophotometer was used to record the fluorescence spectra and an IG-27DS Lab-Serve UV-visible spectrophotometer was used to record the absorbance spectra. The metal ions used for the fluorescence and absorbance titrations were purchased from Sigma-Aldrich and Sisco Research Laboratories Pvt Ltd. as their corresponding salts. Prior to use, solvents suitable for high-performance liquid chromatography (HPLC) were dried according to standard methods. The 1 cm quartz cell used for the fluorescence titrations has a 5 nm-wide slit. The phosphate buffer-acetonitrile solution (1:1) used in these experiments has a pH value of 7.4 and a concentration of 0.1 mM. The metal ion solutions were made in water. Throughout the trials, the concentration of the stock solutions of L₁ remained constant at 1 mM. The solutions in the quartz cell were excited at 510 nm for fluorescence titrations, and a final cuvette concentration of L₁ set at 10 μM in a total volume of 3 mL was reached by dilution with buffer. The scan speed was maintained at 600 nm min⁻¹, and the excitation and emission slit widths were set at 5 nm each. For the tests, perchlorate salts of the metals, namely, Li⁺, Na⁺, Mg²⁺, Al³⁺, K⁺, Ca²⁺, Cr³⁺, Mn²⁺, Fe²⁺, Fe³⁺, Co²⁺, Ni²⁺, Cu⁺, Cu²⁺, Zn²⁺, Cd²⁺, Hg²⁺, and Pb²⁺ were used. Absorbance titration details are the same as those performed in fluorescence studies.

Synthesis and characterization of (L₁)

In a 50 mL round-bottom flask, a mixture of P₂ (0.62 g, 1.44 mmol, 1 eq.), acetylacetone (0.59 mL, 8.68 mmol, 6 eq.), ethanol (15 mL), and a catalytic amount of acetic acid was added. The reaction was refluxed at 100 °C overnight. When the reaction was completed and monitored through TLC, the solvent was removed by evaporation. The crude product was further purified using neutral alumina in an ethyl acetate: petroleum ether (20–40%) solvent system. The compound obtained in good yields was a light pink solid (0.45 g, yield: 60%). **FT-IR (ATR, cm⁻¹)**: 3425, 3343, 2921, 2849, 1719, 1609, 1514, 1425, 1344, 1265, 1197, 1013, 808, 733. **¹H NMR (600 MHz, CDCl₃) MHz δ (ppm)**: 7.98 (d, *J* = 6.78 Hz, 1H), 7.55 (m, 2H), 7.16 (d, *J* = 7.03 Hz, 1H), 6.34 (s, 2H), 6.25 (s, 2H), 3.52 (s, 2H), 3.19 (dq, *J* = 7.04; 1.34 Hz, 4H), 1.92 (s, 6H), 1.91 (s, 3H), 1.69 (s, 2H), 1.5 (s, 3H), 1.31 (t, *J* = 7.23 Hz, 6H); **¹³C NMR (150 MHz, CDCl₃) MHz δ (ppm)**: 166.07, 163.38, 152.62, 150.73, 147.74, 133.45, 129.72, 128.55, 128.21, 124.45, 123.40, 117.84, 104.71, 96.84, 66.92, 38.32, 29.70, 28.92, 18.06, 16.74, 14.68. **ESI-MS**: observed for C₃₁H₃₄N₄O₃ *m/z* = 511.52 [M + H]⁺, calculated for C₃₁H₃₄N₄O₃ = 510.64.

Synthesis and characterization of the {L₁ + Cu²⁺} complex

In a 10 mL round-bottom flask, L₁ (110 mg, 0.39 mmol, 1 eq.) was added to 5 mL ethanol and CuCl₂·2H₂O (66 mg, 0.58 mmol, 1.5 eq.) at room temperature (26 °C) and stirred for 1

hour. On the completion of the reaction, solid precipitates were filtered through the Buchner funnel. The pure product appeared red (50 mg, yield 47%). **FT-IR (ATR, cm⁻¹)**: 3358, 3319, 2983, 2868, 2585, 1653, 1605, 1514, 1307, 1230, 1183, 1009. **¹H NMR (400 MHz, CDCl₃) δ (ppm)**: 11.3 (s, 1H), 7.87 (s, 1H), 7.61 (b, 2H), 7.1 (s, 1H), 6.78 (m, 1H), 6.21 (s, 1H), 6.1 (s, 1H), 3.40 (b, 1H), 3.1 (s, 3H), 2.0 (s, 2H), 1.84 (m, 4H).

Density functional theory (DFT) computation

DFT calculations were performed using Gaussian 09. The coordinates for the initial structure used for the DFT computation were generated using Gauss View 6.0. The optimization was carried out from PM6 to the DFT, and finally, the structure was optimized at the CAM-B3LYP level. The electronic structure calculations for these structures were modeled along with the mixed basis set using the 'Gen' keyword implemented in Gaussian 09. For the Cu atom, we chose the SDD basis set, while the remaining atoms were modeled using the 6-31G(d,p) basis set. Following geometry optimization, frequency calculations were also carried out on the optimized geometry at the same level of theory to assess the nature of stationary points, *i.e.*, whether they are transition states (TS) or higher-order saddle points.

Cell imaging study

L929 and HeLa cells were procured from the National Centre for Cell Science (NCCS), Pune, India. After trypsinization, cells were seeded into a 12-well plate and incubated at 37 °C in a humidified atmosphere of 5% CO₂. The medium was removed, cells were washed with PBS buffer, and then 10 μM concentration of fluorescent probe L₁ was added to each well and incubated for another 1 h. The confocal dishes were washed with PBS to remove excess L₁ and fixed using 4% paraformaldehyde at 4 °C. To this, different concentrations of Cu²⁺ ions were added. The parameters of confocal images such as the excitation and emission ranges of DAPI and L₁ are from 410 to 450 nm and 480 to 560 nm, respectively. For imaging purposes, the cells were washed with PBS buffer and then exposed to DAPI (1:100 dilutions) for 10 min to observe the cell morphology and integrity and further washed with PBS. The specimen samples were mounted on confocal dishes, and the images were taken at 63× magnification using a laser scanning confocal microscope (Zeiss LSM 780,

Germany) at an excitation wavelength of 480 nm and an emission wavelength of 560 nm.

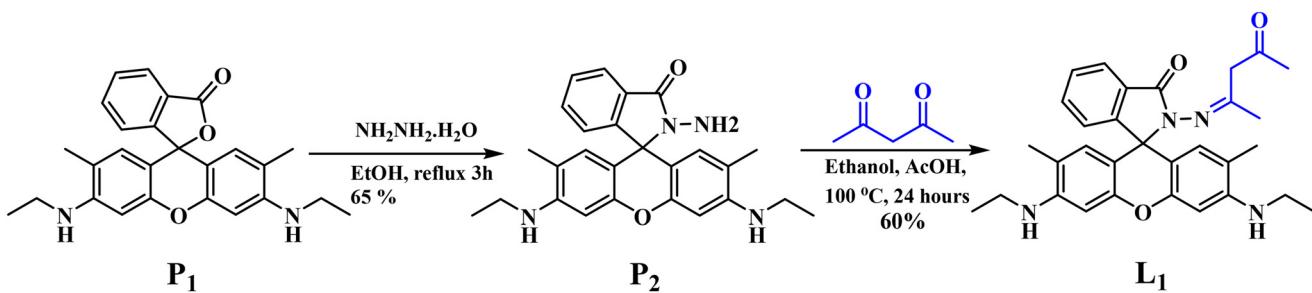

Results and discussion

Synthesis and characterization of probe L₁

As illustrated in Scheme 1, the receptor molecule (L₁) was synthesized *via* the well-known Schiff-base reaction, which involves combining rhodamine hydrazide with acetylacetone in the presence of a catalytic quantity of acetic acid in ethanol. P₂ was synthesized by a previously reported method⁴⁸ *via* the condensation of P₁ with hydrazine hydrate in an ethanol solvent. The receptor molecule (L₁) and precursor were confirmed by various techniques such as ¹H and ¹³C NMR, FTIR spectroscopy, and ESI-MS. The corresponding details of the synthesis and characterization data are given in the experimental section and the ESI[†] (Fig. S1 and S2).

Absorption titration of L₁ with metal ions

The metal ion binding nature of L₁ was studied based on absorption titration in a 1 mM PBS buffer in an ACN/PBS mixture (v/v, 1:1%) at pH = 7.4. In the absence of metal ions, the receptor molecule (L₁) exhibits a characteristic absorbance band of rhodamine positioned at 304 nm corresponding to the π-π* transition due to the closed spirolactam ring. The absorbance spectra of probe L₁ (10 μM) was measured in the presence of various metal ions such as Li⁺, Na⁺, Mg²⁺, Al³⁺, K⁺, Ca²⁺, Cr³⁺, Mn²⁺, Fe²⁺, Fe³⁺, Co²⁺, Ni²⁺, Cu⁺, Cu²⁺, Zn²⁺, Cd²⁺, Hg²⁺, and Pb²⁺ (concentration up to 0–20 equivalents). However, the presence of Cu²⁺ ions only showed a significant change in the absorbance spectrum of L₁, and a new band appeared in the UV-vis spectrum of L₁ at 525 nm, as shown in Fig. 1a and b. The newly generated bands became more intense with the increase in the concentrations of Cu²⁺ metal ions in the solutions and attained a saturation point when the concentration was eight equivalents of Cu²⁺ ions. The emergence of the peak at 525 nm is likely attributed to the spirolactam ring of L₁ opening up in the presence of Cu²⁺ ions and forming the {L₁ + Cu²⁺} complex. Additionally, the absorbance of the 300 nm band decreases while that of the 350 nm band increases, resulting in the isosbestic points at 286 and 329 nm. These points signify that L₁ has been converted to its bound {L₁ + Cu²⁺} complex. From the obtained result, it can

Scheme 1 Design and synthesis of chemoreceptor L₁.

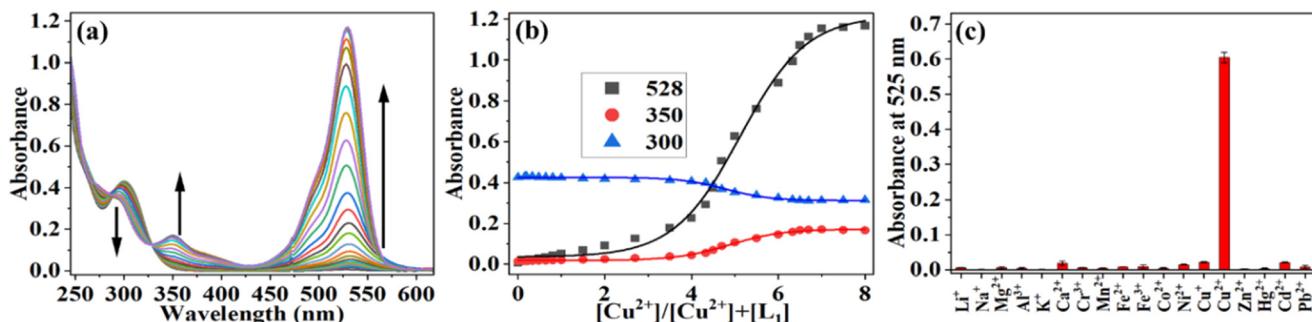

Fig. 1 Absorption spectra were obtained during the titration of L₁ against Cu²⁺ in a 0.1 mM PBS:ACN solvent system. (a) L₁ (10 μM) vs. Cu²⁺ (0–10 eq.), (b) plot of absorbance vs. [Cu²⁺]/[Cu²⁺]+[L₁] mole ratio as a function of wavelength change at different absorption bands, and (c) plot of the change in absorbance at 525 nm (A₀–A) ΔA vs. metal ions.

be concluded that L₁ binds selectively to Cu²⁺. The absorbance spectra of L₁ were not significantly altered by the presence of other metal ions (Fig. 1c and S4†). Furthermore, L₁ showed a visible color change and a fluorescent color change under UV light at 365 nm in the presence of Cu²⁺ ions at different concentrations. The interaction between L₁ and Cu²⁺ resulted in an association constant (K_a) of $0.2 \times 10^{-5} \text{ M}^{-1}$, which was derived using the Benesi–Hildebrand equation (Fig. S5†). Job's plots based on absorption data found a 1:1 complex between L₁ and Cu²⁺ (Fig. S6†).

Fluorescence titration of L₁ with metal ions

In order to explore the selectivity of the receptor system (L₁) towards biologically and environmentally important metal

ions, fluorescence titrations were carried out against 18 different metal ions in aqueous solutions. The receptor L₁ molecule was excited at 510 nm and showed weak fluorescence at 550 nm due to a closed spirolactam ring. However, the presence of Cu²⁺ ions showed a gradual increase in fluorescence intensity at 550 nm band and finally attained a ~28-fold fluorescence enhancement, as shown in Fig. 2a. The quantum yield of L₁ is 0.021, which is enhanced by more than twenty times to 0.46 in the presence Cu²⁺ ions in fluorescence study using quinine bisulfate as the standard. This is due to L₁ consisting of a five-membered spirolactam ring conjugated with acetylacetone suitable binding groups that participate in metal binding. In the presence of Cu²⁺ ions, spiro-ring opening through C–N bond cleavage followed by metal coordination through amide oxygen 'O', imine

(a) Intensity vs. wavelength plot for L₁ ($\lambda_{\text{ex}} = 510 \text{ nm}$) (10 μM) against Cu²⁺ (0–10 eq.) [inset: fluorescence intensity at 558 nm as a function of Cu²⁺ ion concentration], (b) relative fluorescence intensity (I/I_0) vs. wavelength plot for L₁ (10 μM) with different metal ions (100 μM), (c) histogram shows emission intensity of L₁ with different metal ions at 558 nm and (d) photos of the visible color change (top) and fluorescent changes (bottom) of L₁ in the presence of metal ions under UV light at 365 nm.

nitrogen ‘N’ and acetyl enol oxygen ‘O’ atoms result in observable color and fluorescence changes. Furthermore, other metal ions exhibited no significant change in the emission intensity of \mathbf{L}_1 (Fig. 2b). The relative fluorescence intensity (I_0/I) vs. metal ion plot also demonstrates the selectivity of \mathbf{L}_1 towards Cu^{2+} ions (Fig. 2c). The limit of detection was found to be 3.58×10^{-8} M and this was enough to detect Cu^{2+} ions present in drinking water (20 μM set by the US EPA) (Fig. S7†). \mathbf{L}_1 showed a lower detection limit than other fluorescent probes reported in the literature for Cu^{2+} ions (Table S8†). The detection of Cu^{2+} by \mathbf{L}_1 was further demonstrated by observing a distinct naked eye color change from colorless to light pink only in the presence of Cu^{2+} ions in daylight. Additionally, under a hand-held UV lamp with a wavelength of 365 nm, \mathbf{L}_1 exhibited a greenish-yellow fluorescence (Fig. 2d). The other metal ions showed no recognizable color change, except that a very marginal color change was observed in case of Hg^{2+} ions, as shown in Fig. 2d.

In order to check the selective detection of \mathbf{L}_1 by Cu^{2+} ions in the presence of other interference metal ions, comparative fluorescence titrations were carried out. From the result (Fig. S9†), we found that fluorescence intensity returns to that $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ and no fluorescence quenching was observed, indicating specific binding of \mathbf{L}_1 towards Cu^{2+} even in the presence of other metal ions. To determine the optimal pH for $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$, complexation fluorescence titration was performed at different pH values, and it was found that in both cases, \mathbf{L}_1 and complex $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ exhibited high fluorescence in an acidic medium at pH up to 4. However, the $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ complex showed high and unaltered fluorescence emission at pH 5 to 12, whereas in the case of \mathbf{L}_1 , low intensity and weak emission were observed in the pH range of 5–12 (Fig. S10†). These results indicated that probe \mathbf{L}_1 can be used for the detection of Cu^{2+} ions in the pH range of 5–12.

Synthesis of complex $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ and its isolation and characterization

The $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ complex was synthesized from a reaction between \mathbf{L}_1 and $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ in methanol at room temperature. After 1 h, a precipitate was formed, which was filtered and subsequently dried under vacuum (Scheme 2). The isolated copper complex $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ was characterized using various techniques such as absorbance, emission, ^1H and ^{13}C NMR,

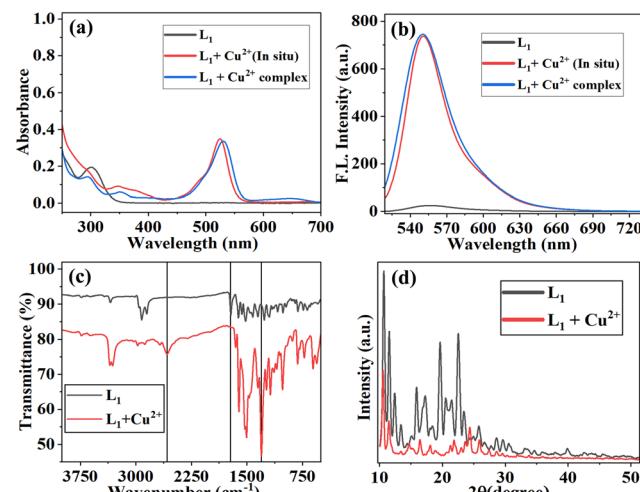

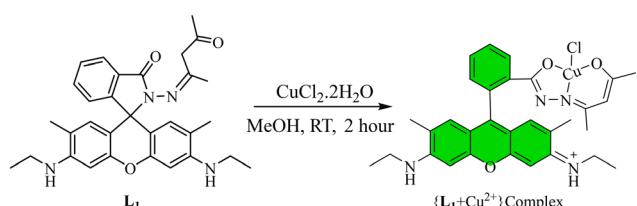

Fig. 3 Characterization of the $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ complex. (a) UV-visible spectra of the $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ complex, (b) fluorescence spectra of the $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ complex, (c) FTIR spectra of \mathbf{L}_1 (black) and $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ (red) complex, and (d) powder-XRD pattern of \mathbf{L}_1 (black) and $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ complex (red).

powder XRD, FTIR spectroscopy, and ESI-MS. The isolated $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ complex spectral features, such as absorbance peaks at ~ 525 nm and emission at 558 nm, are comparable with those of the *in situ*-generated complex species in solutions (Fig. 3a and b). This was further confirmed by comparing the \mathbf{L}_1 and $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ complex NMR spectra. The proton NMR signals corresponding to aromatic and aliphatic protons experience considerable broadening due to the complexation of Cu^{2+} ions, as can be noticed in Fig. S3.† The infrared spectra of \mathbf{L}_1 showed significant shifts in the vibrational frequencies of 2989 and 1635 upon binding to Cu^{2+} (Fig. 3c). The crystallization of \mathbf{L}_1 and $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ complex did not yield a single crystal appropriate for X-ray diffraction. Powder-XRD studies of both \mathbf{L}_1 and $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ complex indicated good crystallinity (Fig. 3d).

Coordination features of the $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ complex by DFT computation

The experimental study unequivocally supported the development of a 1:1 complex when Cu^{2+} ions bind to receptor \mathbf{L}_1 . In order to delineate the coordination features of the $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ complex, DFT calculations were performed by Gaussian 09 using the M06L level of theory. The structure of \mathbf{L}_1 was used as the initial input and optimized at the CAM-B3LYP level of theory using the 6-31G(d,p) basis set and the corresponding optimized structure and highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO). Later, Cu^{2+} ions were positioned close to the binding arms of the $-\text{C=O}$ and $-\text{N}$ sites of \mathbf{L}_1 and relaxed to explain the Cu^{2+} ion binding capability towards both of these structures (Fig. 4a). The HOMO and LUMO of the corresponding Cu^{2+} ion addition complex $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ are shown in Fig. 4(b) and (c), respectively.

Scheme 2 Synthesis and probable reaction mechanism of the $\{\mathbf{L}_1 + \text{Cu}^{2+}\}$ complex.

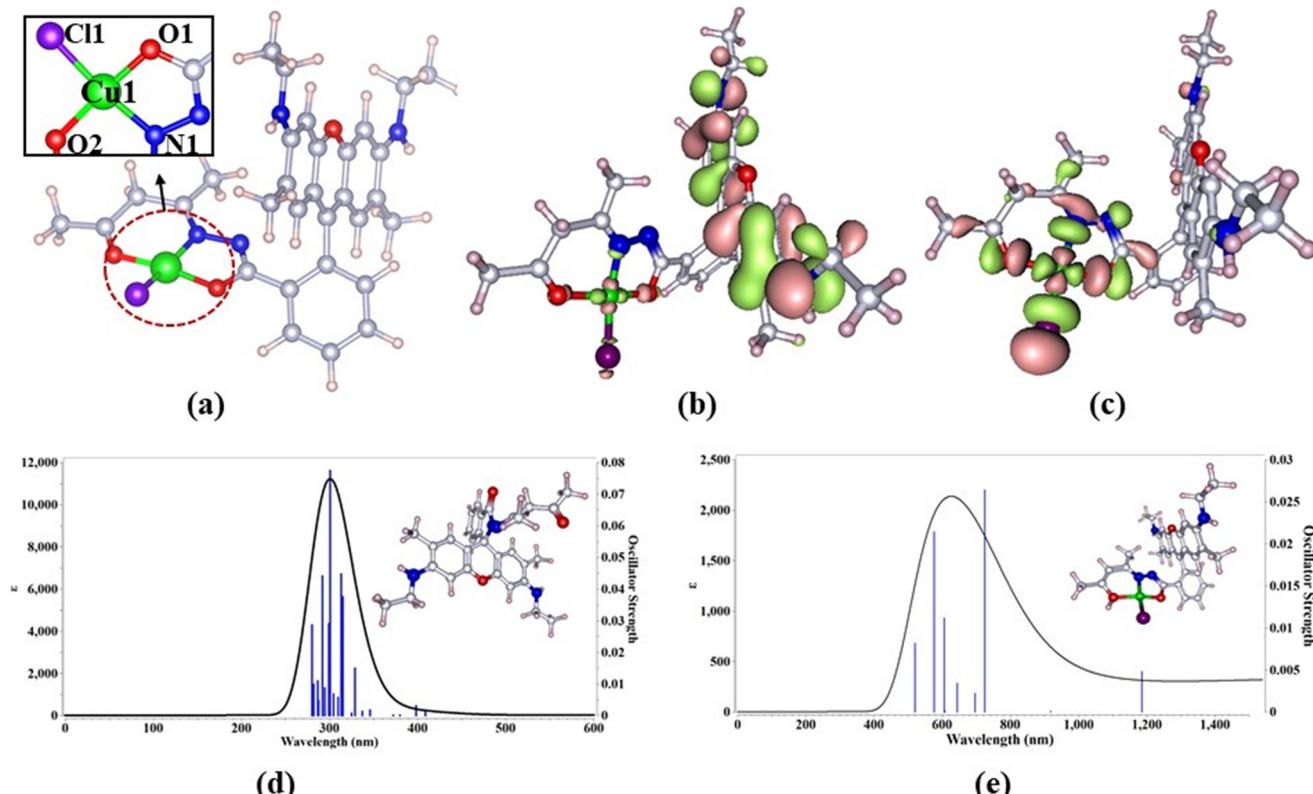

Fig. 4 (a) CAM-B3LYP/Gen (6-31G(d,p) + SDD) optimized structure of $\{L_1 + Cu^{2+}\}$ along with (b) HOMO and (c) LUMO orbitals, (d) TD-DFT absorption spectra of receptor L_1 , and (e) absorption spectra of $\{L_1 + Cu^{2+}\}$ complex.

In the complex $\{L_1 + Cu^{2+}\}$, the corresponding metal ion is bound to the conjugate through two oxygen centers (Cu-O1 and Cu-O2), a nitrogen center (Cu-N), and a chloride center (Cu-Cl), resulting in a four-coordinated complex. The Cu-O1 and Cu-O2 distances in these complexes are 1.85 Å and 1.96 Å, and the Cu-N and Cu-Cl distances in these complexes are 1.99 Å and 2.08 Å for Cu²⁺, respectively, indicating a substantially greater binding for Cu²⁺. The O1-Cu²⁺-O2 and Cl1-Cu-N1 angles (170° and 172°) in both situations deviate slightly from the anticipated square planar geometry despite the fact that the coordination number is four. It is clear from a comparison with the ideal geometry that the fitting to square planar geometry is preferable for Cu²⁺ centers. Therefore, the coordination cores in the $\{L_1 + Cu^{2+}\}$ complex fit to a slightly warped square planar.

The HOMO-LUMO energy gaps are used to characterize the kinetic stability and chemical reactivity of the compounds. The HOMO and LUMO of receptor L₁ are -5.09 eV and -0.86 eV, respectively, and the corresponding energy gap (ΔE_{H-L}) is 4.23 eV. The HOMO and LUMO energies of the complex $\{L_1 + Cu^{2+}\}$ formed upon the entry of Cu²⁺ into conjugation with receptor L₁ are -10.38 eV and -9.93 eV, respectively, and the corresponding energy gap (ΔE_{H-L}) is 0.45 eV. The low energy gap value denotes an easier charge transfer, which affects the sensor activity of the compounds. Due to the ease of donating an electron to the acceptor, soft

receptors with small HOMO-LUMO gaps are more reactive and polarized than those with greater HOMO-LUMO gaps.

Additionally, the optical absorption spectra computed using the TD-DFT/CAM-B3LYP technique and performed in the gas phase are shown in Fig. 4d and e. The TD-DFT electronic absorption spectra of receptor L₁ and the $\{L_1 + Cu^{2+}\}$ complex are well featured. L₁ exhibits an absorption band at 300 nm, and the enol form of $\{L_1 + Cu^{2+}\}$ results in a band at ~592.07 nm. The altered spectral characteristics of the complex $\{L_1 + Cu^{2+}\}$ demonstrate the impact of intramolecular charge transfer and subsequent absorption at higher wavelengths. As a result, the $\{L_1 + Cu^{2+}\}$ complex has a longer wavelength according to TD-DFT studies, which is in agreement with the experimental observations.

Intracellular sensing of Cu²⁺ by fluorescence microscopy

The biological applicability of L₁ to detect Cu²⁺ in L929 and HeLa living cells was investigated using confocal fluorescence microscopy. The cytotoxic and optimal concentrations of L₁ on HeLa and L929 cells were determined by the MTT assay. The cells were incubated with different doses of L₁ (5–100 μM) for 24 h. Notably, it was observed that cells maintained their metabolism at all doses after 24 h of treatment. The metabolically formed formazan was dissolved in dimethyl sulfoxide, and the absorbance was measured at 570 nm. The cell viability is expressed as a percentage relative to the

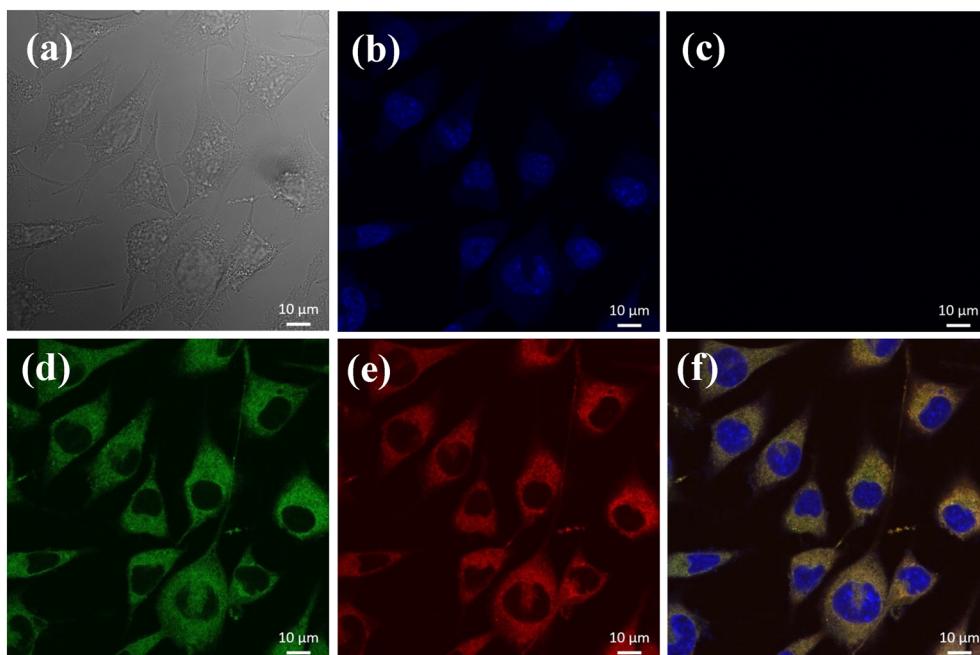

Fig. 5 Confocal fluorescence microscopy images of L929 cells. (a) DIC image, (c) cells incubated only with **L₁** (10 μ M), (d) cells treated with **L₁** followed by Cu²⁺ addition (20 μ M) exhibiting green color and (e) red color, and (f) merged image of b–e.

untreated control (100% cell viability). **L₁** exhibited 85% cell viability rate even at a concentration of 50 μ M, whereas at higher concentrations, marginal cell death was observed (Fig. S11†). The L929 and HeLa cells were incubated in a buffer containing 5 μ M of receptor probe **L₁** for 30 min. They displayed weak intracellular fluorescence due to the spirolactam ring being in the closed form as can be seen from Fig. 5. Upon addition of exogenous Cu²⁺ ion into cells through incubation with varying concentrations of Cu²⁺ ion (0 to 50 μ M). At this stage, the cells were visualized using a fluorescence microscope with a DAPI filter and bright intracellular green fluorescence was observed in the cytoplasm and around the nucleus (Fig. 5). Even when **L₁** was incubated with HeLa cells followed by Cu²⁺ ion addition, cells exhibited intracellular green fluorescence emissions (Fig. S11†). The DIC image for each conducted experiment confirmed that cells were viable throughout the imaging study and the merged image provided evidence that the fluorescence is displayed through cells. These results indicated that **L₁** can permeate into cells and effective intracellular Cu²⁺ ion imaging revealed that **L₁** exhibits strong fluorescence.

Conclusions

A novel and simple rhodamine-based receptor molecule (**L₁**) was synthesized *via* the Schiff base reaction and characterized using various spectroscopic techniques, including FTIR spectroscopy, ¹H and ¹³C NMR, and ESI-MS. In an aqueous buffer with a pH of 7.4, **L₁** demonstrates selectivity to Cu²⁺ ions among the different metal ions examined, indicating a 28-fold increase in fluorescence intensity. The receptor molecule exhibits a pink fluorescence color when Cu²⁺ is present among the other metal ions investigated under UV light at 365 nm.

The **L₁** can detect Cu²⁺ ions up to the lowest concentration of 3.58×10^{-8} M in an aqueous buffer, which is well below the limit of 20 mM set by EPA for the Cu²⁺ concentration in drinking water. The interaction between **L₁** and Cu²⁺ was studied by absorbance spectra, wherein isosbestic points at 286 and 329 nm were observed. Job's plot absorption spectra corroborated the 1:1 complex formation between **L₁** and Cu²⁺ ions. DFT simulations provide more evidence for the formation of the {**L₁ + Cu²⁺}** complex and the coordination cores in the {**L₁ + Cu²⁺}** complex fit to a slightly distorted square planar. The computed HOMO-LUMO reduced energy gap value indicates a simpler charge transfer, which influences the activity of the compound's sensors. Longer wavelengths are absorbed into the visible area when Cu²⁺ ions are added to receptor **L₁**, according to TD-DFT simulations. Further, the biological property of **L₁** was used to detect Cu²⁺ ions in living cells (L929 and HeLa) in biologically relevant media. As a result, the use of molecular receptor **L₁** may be extended to detect Cu²⁺ ions in biological tissues and *in vivo*.

Conflicts of interest

There are no conflicts to declare.

Acknowledgements

A. S. gratefully acknowledges the financial support from the Sardar Vallabhbhai National Institute of Technology, Surat for a seed money/research grant. M. P. thanks SVNIT Surat for the fellowship. The authors acknowledge the services provided by the central facility at IIT Bombay for the confocal cell imaging studies.
