## Highly selective 1,4-NADH regeneration via hydrogenated NAD<sup>+</sup> analogs using a Pt/SiO<sub>2</sub> catalyst with low pressure hydrogen gas

 Makoto Hirano,<sup>a</sup> Wataru Onodera,<sup>b</sup> Masazumi Tamura<sup>b,c</sup> and Yutaka Amao<sup>b,d</sup>

**The hydrogenation of nicotinamide analogs using a Pt/SiO<sub>2</sub> catalyst, followed by hydride transfer to NAD<sup>+</sup>, results in the highly selective regeneration of 1,4-NADH. *N*-Methyl nicotinamide exhibits the highest reactivity, achieving 98% selectivity at 20 °C under 1 atm H<sub>2</sub>. This strategy provides a practical and sustainable pathway for 1,4-NADH regeneration.**

Enzymes catalyze highly selective chemical reactions. Many enzymatic reactions rely on small-molecule cofactors, known as coenzymes, which act as redox mediators within the catalytic cycle.<sup>1</sup> Nicotinamide adenine dinucleotide (NAD<sup>+</sup>)—which undergoes hydride addition at the 4-position of its pyridinium ring to form 1,4-dihydronicotinamide adenine dinucleotide (1,4-NADH)—participates in a reversible redox cycle that acts as an essential biological electron carrier in dehydrogenase-catalyzed reactions (Fig. 1a).<sup>2</sup> In industrial enzymatic processes, 1,4-NADH functions as a key reductant but is oxidized back to NAD<sup>+</sup> during the reaction. Efficient NAD<sup>+</sup> regeneration is essential for sustained enzymatic activity. While various methods for NAD<sup>+</sup> regeneration have been explored,<sup>3–17</sup> the hydrogenation method has attracted attention as a green chemistry approach.<sup>6</sup> Furthermore, heterogeneous catalysts offer advantages such as reduced waste generation and easy separation of products from the catalyst,<sup>7</sup> compared with homogeneous catalysts.<sup>8</sup> For example, the Pt/Al<sub>2</sub>O<sub>3</sub> catalyst has been used for NAD<sup>+</sup> hydrogenation but has shown limited selectivity (20%)<sup>9</sup> due to undesired byproduct formation, such as the non-biologically active 1,6-dihydro isomer (Fig. S1).<sup>10</sup> The Pt/TiO<sub>2</sub> catalyst improved

selectivity (63%),<sup>11</sup> and recent catalysts such as the Pt-Sn/SiO<sub>2</sub> catalyst (90%)<sup>12</sup> and Rh/Ni-TiO<sub>2</sub> catalyst (91%)<sup>13</sup> show further enhancement, though optimization remains (Table S1).

Parallel to the study of NAD<sup>+</sup> hydrogenation, research has focused on understanding the molecular structure of the NAD<sup>+</sup> model<sup>18,19</sup> and designing structural analogs<sup>20–22</sup> or mimic NAD<sup>+</sup>s (mNAD<sup>+</sup>s) (Fig. 1b). These mNAD<sup>+</sup>s include intermediates found in metabolic pathways, such as nicotinamide mononucleotide (NMN<sup>+</sup>).<sup>23,24</sup> Others include synthetic analogs with simplified nicotinamide structures, such as *N*-benzyl nicotinamide (BNA<sup>+</sup>)<sup>25</sup> and *N*-methyl nicotinamide (MNA<sup>+</sup>).<sup>26</sup> The mNAD<sup>+</sup>s demonstrate that reduced dihydropyridines donate a hydride specifically to the C4 position of the pyridinium ring, with a *syn* transition state found to be the lowest in energy.<sup>27,28</sup> Notably, 1,4-dihydronicotinamide (1,4-BNAH) has been shown to reduce NAD<sup>+</sup> to 1,4-NADH through C4 hydride delivery and is used as a hydride donor in cofactor recycling.<sup>29,30</sup>

Recently, we reported a Pt/SiO<sub>2</sub>-catalyzed hydrogenation system that efficiently converts BNA<sup>+</sup> to 1,4-BNAH with a production rate that is 6.8 times higher than that of 1,4-NADH formation.<sup>31</sup> Based on this, we hypothesized that the hydrogenation of mNAD<sup>+</sup> species such as BNA<sup>+</sup> would promote the reduction of NAD<sup>+</sup>, enabling the selective formation of 1,4-NADH (Fig. 1c). To evaluate this hypothesis, we investigated the following steps and designed an integrated system: (step 1) hydrogenation of mNAD<sup>+</sup> species (NMN<sup>+</sup>, BNA<sup>+</sup>, MNA<sup>+</sup>) using a Pt/SiO<sub>2</sub> catalyst and (step 2) evaluation of the hydride-donating ability of the reduced mNAD<sup>+</sup> forms without Pt/SiO<sub>2</sub> catalyst. Finally, one-pot production of 1,4-NADH was performed using the hydrogenated mNAD<sup>+</sup>s. The system was optimized by adjusting the molar ratio of mNAD<sup>+</sup> to NAD<sup>+</sup>. Importantly, the entire process proceeds efficiently under low-pressure hydrogen (1 atm), which offers key advantages for integration with enzymatic systems that typically require mild operating conditions.<sup>32</sup> By contrast, the majority of heterogeneous NAD<sup>+</sup> hydrogenation systems reported to date require elevated hydrogen pressures (Table S1). Moreover, operating at ambient pressure enables the direct use of hydrogen generated

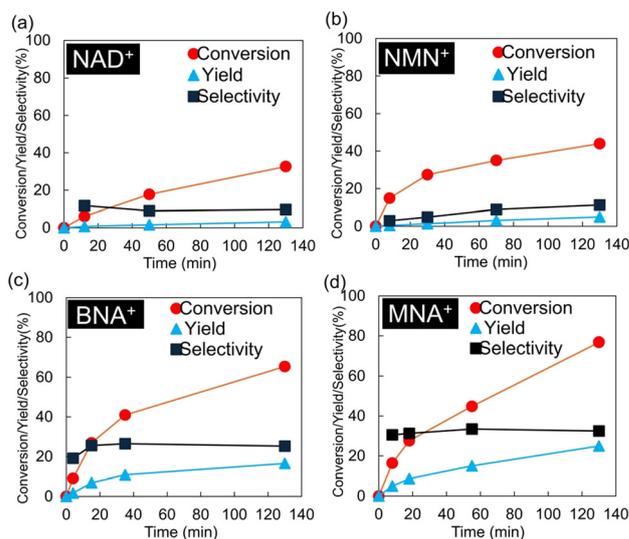

**Fig. 1** (a)  $\text{NAD}^+$  and 1,4-NADH. (b)  $\text{mNAD}^+$ s, including  $\text{NMN}^+$ ,  $\text{BNA}^+$ , and  $\text{MNA}^+$ . (c) Schematic of 1,4-NADH production: step 1 involves the  $\text{Pt}/\text{SiO}_2$ -catalyzed hydrogenation of  $\text{mNAD}^+$  to its reduced form ( $\text{mNADH}$ ), followed by step 2, where hydride transfer from  $\text{mNADH}$  to  $\text{NAD}^+$  results in the production of 1,4-NADH.

from renewable sources, eliminating compression steps and thereby improving the system's environmental and economic sustainability.<sup>33</sup> This approach thus offers a practical and sustainable strategy for 1,4-NADH regeneration, well-suited for integration into biocatalytic systems.

As a first step, the hydrogenation of  $\text{mNAD}^+$  species was investigated, as described in step 1 (Fig. 1c). A  $\text{Pt}/\text{SiO}_2$  catalyst with 0.5 wt% was selected based on previous studies.<sup>31</sup>  $\text{NMN}^+$ ,  $\text{BNA}^+$ , and  $\text{MNA}^+$  were employed as  $\text{mNAD}^+$ s based on them being more negative than the  $\text{NAD}^+/\text{NADH}$  couple (Table S2). Details of the catalyst preparation and characterization are provided in Fig. S2–S4 and Tables S3–S5, while the full experimental procedures are outlined in Fig. S5–S17 of the SI. Performance parameters were calculated using five equations: conversion (eqn (S1), %), yield (eqn (S2), %), selectivity (eqn (S3), %), production rate of the 1,4-reduced isomers of  $\text{NAD}^+$  and its analogs (eqn (S4),  $\text{mmol h}^{-1}$ ) and the production rate per Pt surface site (eqn (S5),  $\text{mmol}(\text{mmol Pt}_{\text{site}})^{-1} \text{h}^{-1}$ ), hereafter expressed simply as  $\text{h}^{-1}$ ). Based on catalyst characterization, Pt particles were found to have an average size of 2.7–2.8 nm and to be predominantly present as metallic Pt. Hydrogenation was conducted using  $\text{NAD}^+$ ,  $\text{NMN}^+$ ,  $\text{BNA}^+$ , and  $\text{MNA}^+$  (each at  $1.8 \text{ mmol L}^{-1}$ ) as substrates in 20 mL of solution containing 10 mg of  $\text{Pt}/\text{SiO}_2$  catalyst under 1 atm  $\text{H}_2$ , 20 °C (Fig. S18–S21). After 130 min, the conversion, yield, and selectivity for the corresponding 1,4-dihydro products (1,4-NADH, 1,4-NMNH, 1,4-BNAH, and 1,4-MNAH) were as follows:  $\text{NAD}^+$ : 33%, 3.1%, and 9.7%;  $\text{NMN}^+$ : 44%, 4.9%, and 11%;  $\text{BNA}^+$ : 65%, 17%, and 25%;  $\text{MNA}^+$ : 77%, 25%, and 32% (Fig. 2). The production rates of the respective 1,4-dihydro species were 12, 11, 94, and  $128 \text{ h}^{-1}$  for 1,4-NADH, 1,4-NMNH, 1,4-BNAH, and 1,4-MNAH, respectively (Fig. S22). As with 1,4-BNAH, the 1,4-MNAH production rate was higher than that of 1,4-NADH. In contrast, the production rate of  $\text{NMN}^+$  was comparable to that of  $\text{NAD}^+$  and significantly lower than those of  $\text{BNA}^+$  and  $\text{MNA}^+$ . These results suggest that the structural features of the substrates influence their reactivity. In particular, the higher production rate of  $\text{BNA}^+$  and  $\text{MNA}^+$  is likely attributable to their simplified molecular structures, which lack the bulky ribose and adenine moieties present in  $\text{NAD}^+$  and  $\text{NMN}^+$ . The regioselectivity of the hydrogenation products was determined by  $^1\text{H}$  NMR spectroscopy as hydrogenation can occur at the C4 of the pyridine ring. Hydrogenation reactions of  $\text{NAD}^+$  and  $\text{mNAD}^+$ s were conducted with

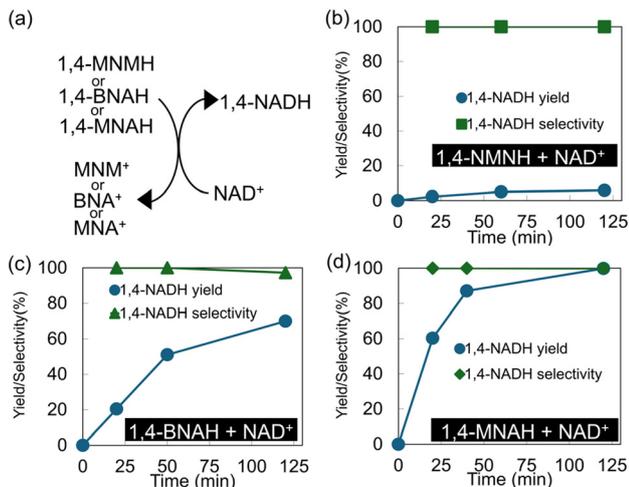

**Fig. 2** Hydrogenation of  $\text{mNAD}^+$ s. Reaction conditions:  $1.8 \text{ mmol L}^{-1}$  (a)  $\text{NAD}^+$ , (b)  $\text{NMN}^+$ , (c)  $\text{BNA}^+$ , or (d)  $\text{MNA}^+$  in 20 mL of Tris-HCl buffer (pH 8.8), with 20 mg of 0.5 wt%  $\text{Pt}/\text{SiO}_2$  catalyst, under 1 atm  $\text{H}_2$ , 20 °C.

$8.0 \text{ mmol L}^{-1}$  of  $\text{NAD}^+$ ,  $\text{NMN}^+$ ,  $\text{BNA}^+$ , or  $\text{MNA}^+$  in 20 mL of Tris-HCl buffer (pH 8.8) with 20 mg of the  $\text{Pt}/\text{SiO}_2$  catalyst under 1 atm  $\text{H}_2$ , 20 °C. Time-dependent  $^1\text{H}$  NMR spectra are shown in Fig. S23–S26. NMR and HPLC data showed consistent 1,4-dihydro product concentrations.

To identify suitable  $\text{mNAD}^+$ s for hydride transfer to  $\text{NAD}^+$ , we investigated the reactivity of 1,4-reduced  $\text{mNAD}^+$  species toward  $\text{NAD}^+$  and the resulting formation of 1,4-NADH (Fig. 3a). Hydride transfer from 1,4-MNMH, 1,4-BNAH, and 1,4-MNAH (each at  $8 \text{ mmol L}^{-1}$  in a total reaction volume of 10 mL) to  $\text{NAD}^+$  ( $4 \text{ mmol L}^{-1}$ ) was monitored by  $^1\text{H}$  NMR spectroscopy (Fig. S27–S29). In all cases, the signals corresponding to the hydride donors and  $\text{NAD}^+$  gradually decreased over time, while the signal attributed to 1,4-NADH increased accordingly. The time-dependent concentration profiles of 1,4-MNMH, 1,4-BNAH, 1,4-MNAH, and 1,4-NADH are shown in Fig. 3b–d. The initial formation rates of 1,4-NADH (within the first 20 min) were  $2.7 \times 10^{-3} \text{ mmol h}^{-1}$  for 1,4-MNMH,  $25 \times 10^{-3} \text{ mmol h}^{-1}$  for 1,4-BNAH, and  $72 \times 10^{-3} \text{ mmol h}^{-1}$  for 1,4-MNAH (Fig. S30). After 120 min, the yields of 1,4-NADH reached 5.9%, 70%, and

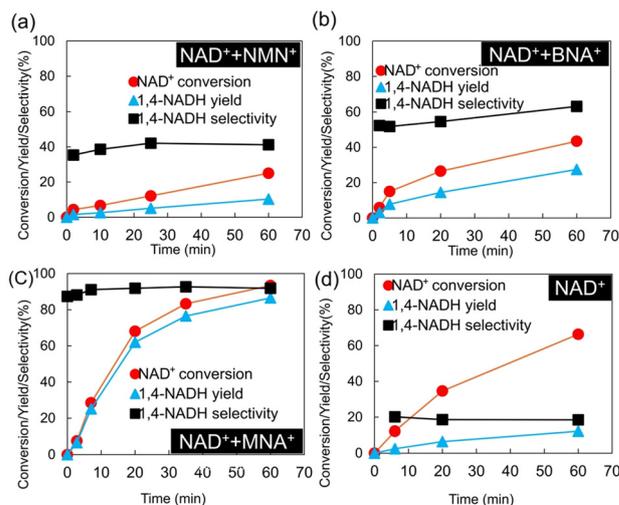

**Fig. 3** (a) Production of 1,4-NADH from  $\text{NAD}^+$  using 1,4-MNMH, 1,4-BNAH, or 1,4-MNAH as hydride donors. Reaction conditions are  $8 \text{ mmol L}^{-1}$  of (b) 1,4-MNMH, (c) 1,4-BNAH, or (d) 1,4-MNAH and  $4 \text{ mmol L}^{-1}$   $\text{NAD}^+$  in  $0.1 \text{ mol L}^{-1}$  Tris-HCl buffer (pH 8.8) at  $20^\circ \text{C}$ . The reaction volume was  $10 \text{ mL}$ .

99% for 1,4-MNMH, 1,4-BNAH, and 1,4-MNAH, respectively, with 1,4-selectivities of 93%, 97%, and 99%, respectively. 1,4-MNAH shows the highest hydride transfer rate, consistent with its redox potential (Table S2).

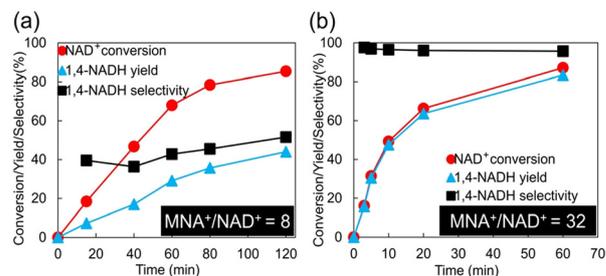

Next, the effect of the  $\text{Pt/SiO}_2$  catalyst on the hydride transfer from hydrogenated  $\text{MNA}^+$  to  $\text{NAD}^+$ , step 2 in the reaction scheme (Fig. 1c), was examined (Fig. S31). A 20-mL solution containing  $\text{MNA}^+$  ( $8 \text{ mmol L}^{-1}$ ) was hydrogenated over 20 mg of  $\text{Pt/SiO}_2$  at  $20^\circ \text{C}$  under 1 atm of  $\text{H}_2$  for 30 min. After the reaction, the catalyst was removed by filtration, and the resulting solution was divided into two portions.  $\text{NAD}^+$  was added to both solutions to a final concentration of  $4 \text{ mmol L}^{-1}$ . One of the solutions was then treated with an additional 10 mg of  $\text{Pt/SiO}_2$ . The 1,4-NADH and 1,4-MNAH concentrations were monitored using  $^1\text{H}$  NMR spectroscopy (Fig. S32). The formation rates of 1,4-NADH were  $25 \times 10^{-3} \text{ mmol h}^{-1}$  in the absence of the catalyst and  $28 \times 10^{-3} \text{ mmol h}^{-1}$  in its presence, indicating no significant catalytic effect on the hydride transfer from 1,4-MNAH to  $\text{NAD}^+$ .

Finally, the one-pot conversion of  $\text{NAD}^+$  to 1,4-NADH *via* the hydrogenation of  $\text{mNAD}^+$  (Fig. 1c) was investigated. Reactions were performed in  $10 \text{ mL}$  of solution containing  $\text{NAD}^+$  ( $0.5 \text{ mmol L}^{-1}$ ) and either  $\text{NMN}^+$ ,  $\text{BNA}^+$ , or  $\text{MNA}^+$  (each at  $8 \text{ mmol L}^{-1}$ ), using 10 mg of 0.5 wt%  $\text{Pt/SiO}_2$  under 1 atm  $\text{H}_2$ ,  $20^\circ \text{C}$  (Fig. 4a–c and Fig. S33–S35). After 60 min, the respective  $\text{NAD}^+$  conversion, 1,4-NADH yield, and 1,4-selectivity were as follows: 25%, 10%, and 60% for  $\text{NMN}^+$ ; 43%, 27%, and 63% for  $\text{BNA}^+$ ; and 92%, 87%, and 92% for  $\text{MNA}^+$ . The production rates were  $0.6 \times 10^{-3}$ ,  $4.7 \times 10^{-3}$ , and  $7.1 \times 10^{-3} \text{ mmol h}^{-1}$  for  $\text{NMN}^+$ ,  $\text{BNA}^+$ , and  $\text{MNA}^+$ , corresponding to 5.8, 44, and  $68 \text{ h}^{-1}$ , respectively (Fig. S36). For comparison, a control experiment using  $\text{NAD}^+$  alone under identical conditions showed a conversion of 66%, a 1,4-NADH yield of 12%, and a selectivity of 18% after 60 min (Fig. 4d), with a production rate of  $1.2 \times 10^{-3} \text{ mmol h}^{-1}$  ( $12 \text{ h}^{-1}$ ). These findings clearly demonstrate that the

**Fig. 4** Production of 1,4-NADH from  $\text{NAD}^+$  *via* the hydrogenation of  $\text{mNAD}^+$ s. Reactions were performed with  $8 \text{ mmol L}^{-1}$  of (a)  $\text{NMN}^+$ , (b)  $\text{BNA}^+$ , or (c)  $\text{MNA}^+$  and  $0.5 \text{ mmol L}^{-1}$   $\text{NAD}^+$  in  $10 \text{ mL}$  of  $0.1 \text{ mol L}^{-1}$  Tris-HCl buffer (pH 8.8) at  $20^\circ \text{C}$ . (d)  $0.5 \text{ mmol L}^{-1}$   $\text{NAD}^+$  under the same conditions, without  $\text{mNAD}^+$ .

hydrogenation of  $\text{mNAD}^+$ s, particularly  $\text{MNA}^+$ , over  $\text{Pt/SiO}_2$  enables the development of a one-pot system for the efficient and selective conversion of  $\text{NAD}^+$  to its enzymatically active form, 1,4-NADH.  $\text{MNA}^+$ 's high 1,4-NADH productivity likely stems from its superior hydrogenation reactivity and hydride-donating ability. To optimize the concentration of  $\text{MNA}^+$ , the effect of the  $\text{MNA}^+/\text{NAD}^+$  molar ratio on the reaction was investigated. The  $\text{NAD}^+$  concentration was fixed at  $0.5 \text{ mmol L}^{-1}$ , while  $\text{MNA}^+$  concentrations of 4 and  $16 \text{ mmol L}^{-1}$  (corresponding to  $\text{MNA}^+/\text{NAD}^+$  molar ratios of 8 and 32, respectively) were employed. The time-course profiles for each condition are presented in Fig. 5. At an  $\text{MNA}^+$  concentration of  $4 \text{ mmol L}^{-1}$  (molar ratio = 8), the  $\text{NAD}^+$  conversion, 1,4-NADH yield, and selectivity after 120 min were 85%, 44%, and 51%, respectively. In contrast, using  $16 \text{ mmol L}^{-1}$   $\text{MNA}^+$  (molar ratio = 32) yielded values of 88%, 83%, and 96%, respectively, after 60 min. Remarkably, after 3 minutes of reaction, the system reached 16% conversion and 16% yield, with a selectivity of 98%. The corresponding 1,4-NADH production rates for the two concentrations were  $1.3 \times 10^{-3}$  and  $14 \times 10^{-3} \text{ mmol h}^{-1}$  or

**Fig. 5**  $\text{NAD}^+$  hydrogenation with different  $\text{MNA}^+/\text{NAD}^+$  molar ratios. The reaction was carried out in  $20 \text{ mL}$  of  $0.1 \text{ mol L}^{-1}$  Tris-HCl Buffer (pH 8.8) containing  $\text{NAD}^+$  ( $0.5 \text{ mmol L}^{-1}$ ) and  $\text{MNA}^+$  at either (a)  $4 \text{ mmol L}^{-1}$  ( $\text{MNA}^+/\text{NAD}^+ = 8$ ) or (b)  $16 \text{ mmol L}^{-1}$  ( $\text{MNA}^+/\text{NAD}^+ = 32$ ), using 10 mg of 0.5 wt%  $\text{Pt/SiO}_2$  catalyst under 1 atm  $\text{H}_2$  at  $20^\circ \text{C}$ .

12 and 130 h<sup>-1</sup> (Fig. S37). The concentration of 1,4-MNAH during the reaction was monitored using HPLC (Fig. S38). The 1,4-MNAH concentration profiles (Fig. S39) revealed that higher MNA<sup>+</sup> concentrations led to faster 1,4-MNAH accumulation. These findings indicate that increasing the MNA<sup>+</sup> concentration effectively promotes hydride transfer from 1,4-MNAH to NAD<sup>+</sup>.

Comparison of the 1,4-NADH formation rates in Fig. 1c revealed the following trends. In step 1, the hydrogenation of MNA<sup>+</sup> (8 mmol L<sup>-1</sup>) yielded 1,4-MNAH at a rate of 68 × 10<sup>-3</sup> mmol h<sup>-1</sup>. In step 2, addition of NAD<sup>+</sup> (4 mmol L<sup>-1</sup>) to the hydrogenated MNA<sup>+</sup> solution yielded a 1,4-NADH formation rate of 28 × 10<sup>-3</sup> mmol h<sup>-1</sup>. In a one-pot system combining steps 1 and 2, a mixture of MNA<sup>+</sup> (8 mmol L<sup>-1</sup>) and NAD<sup>+</sup> (0.5 mmol L<sup>-1</sup>) was hydrogenated directly, and the rate was 14 × 10<sup>-3</sup> mmol h<sup>-1</sup>. In contrast, the direct hydrogenation of NAD<sup>+</sup> (0.5 mmol L<sup>-1</sup>) in the absence of MNA<sup>+</sup> yielded only 9.3 × 10<sup>-4</sup> mmol h<sup>-1</sup> of 1,4-NADH. Although the comparisons are limited by the concentration differences among the setups, these results suggest that MNA<sup>+</sup> is preferentially hydrogenated over NAD<sup>+</sup> on the Pt/SiO<sub>2</sub> catalyst and serves as a selective hydride donor.

We developed a one-pot system for 1,4-NADH regeneration via Pt/SiO<sub>2</sub>-catalyzed MNA<sup>+</sup> hydrogenation followed by hydride transfer to NAD<sup>+</sup>, achieving 98% selectivity and 87% yield at 20 °C and 1 atm H<sub>2</sub> in 60 min. In this study, MNA<sup>+</sup> was used in excess as a hydride shuttle; however, future efforts will focus on improving its hydrogenation selectivity (e.g., through surface modification<sup>34</sup>) to enable mNAD<sup>+</sup> to work as a mediator.
