# Enhancing electrocatalytic CO<sub>2</sub> reduction via engineering substrate–cluster interaction†

Qian Sun,<sup>a</sup> Huiru Yang,<sup>\*a</sup> Chunmei Zhang<sup>id</sup> <sup>\*ac</sup> and Aijun Du<sup>id</sup> <sup>b</sup>

Cu clusters exhibit exceptional performance in the electrocatalytic carbon dioxide reduction reaction (CO<sub>2</sub>RR) due to their tunable size. Using first-principles calculations, we systematically investigate the CO<sub>2</sub>RR on small Cu<sub>*n*</sub> clusters (*n* = 3, 8, 13) anchored on a T'-WTe<sub>2</sub> substrate, denoted as Cu<sub>*n*</sub>@T'-WTe<sub>2</sub>. Given that the hydrogen evolution reaction (HER) often competes with the CO<sub>2</sub>RR, we further investigated the competition between the CO<sub>2</sub>RR and HER. Our results show that Cu<sub>*n*</sub>@T'-WTe<sub>2</sub> outperforms pure Cu<sub>*n*</sub> clusters as catalysts, with enhanced CO<sub>2</sub>RR activity. The CO<sub>2</sub>RR performance of Cu<sub>*n*</sub>@T'-WTe<sub>2</sub> enhances with increasing cluster size, and surpasses the HER activity in Cu<sub>13</sub>@T'-WTe<sub>2</sub>. This enhancement stems from the substrate–cluster interactions, where the buckled “non-uniform surface” of T'-WTe<sub>2</sub> deforms the larger Cu<sub>13</sub> cluster, optimizing the CO<sub>2</sub>RR efficiency. We propose a potential strategy for WTe<sub>2</sub>-supported Cu clusters to boost CO<sub>2</sub>RR while suppressing HER by leveraging substrate-supported Cu clusters.

## 1. Introduction

The accumulation of greenhouse gases, particularly carbon dioxide (CO<sub>2</sub>), drives global warming and poses significant environmental and energy challenges.<sup>1,2</sup> To address rising energy demands and mitigate CO<sub>2</sub> emissions, researchers have explored various strategies to convert CO<sub>2</sub> into valuable chemicals and feedstocks,<sup>3</sup> including chemical reforming,<sup>4,5</sup> bioconversion,<sup>6</sup> photocatalysis,<sup>7,8</sup> and electrocatalysis.<sup>9,10</sup> Among them, the electrochemical CO<sub>2</sub> reduction reaction (CO<sub>2</sub>RR) stands out as a promising approach, transforming CO<sub>2</sub> into valuable products<sup>8,10–12</sup> like methane (CH<sub>4</sub>),<sup>6,13</sup> formic acid (HCOOH),<sup>14</sup> and methanol (CH<sub>3</sub>OH).<sup>15,16</sup> However, the CO<sub>2</sub>RR faces challenges such as low efficiency and poor product selectivity<sup>4,9,17</sup> exacerbated by the competing hydrogen evolution reaction (HER), which significantly reduces the performance of the CO<sub>2</sub>RR.<sup>18</sup>

To overcome these limitations, significant efforts have focused on designing efficient electrocatalysts that activate inert CO<sub>2</sub> molecules while suppressing the competitive HER. Various systems, including metals,<sup>19,20</sup> metal oxides,<sup>21,22</sup> clusters,<sup>23</sup> carbon-based materials,<sup>24,25</sup> and metal–organic frameworks,<sup>26,27</sup> have been explored. Among them, clusters, in particular Cu clusters, demonstrate excellent CO<sub>2</sub>RR catalytic

performance.<sup>28,29</sup> When supported on substrates, the synergistic interaction between the substrate and cluster significantly influences the CO<sub>2</sub>RR efficiency.<sup>30</sup> Thus, optimizing the substrate–cluster pairing is critical to maximizing the CO<sub>2</sub>RR activity and minimizing HER interference.

In this study, we employ first-principles calculations to examine the CO<sub>2</sub>RR performance of Cu<sub>*n*</sub> clusters (*n* = 3, 8, 13) anchored on a T'-WTe<sub>2</sub> substrate denoted as Cu<sub>*n*</sub>@WTe<sub>2</sub>.<sup>31–33</sup> Compared to unsupported Cu<sub>*n*</sub> (Cu<sub>3</sub>, Cu<sub>8</sub>, and Cu<sub>13</sub>),<sup>28,34–36</sup> our findings reveal that the T'-WTe<sub>2</sub> substrate reduces the absolute limiting potential for the CO<sub>2</sub>RR process ( $|U_L|$ ),<sup>37</sup> while inhibiting the competitive HER. This improvement is attributed to the strong distortion of larger Cu<sub>13</sub> clusters by the buckled T'-WTe<sub>2</sub> surface, facilitating rapid charge transfer between the cluster and substrate. Our work provides an effective approach for enhancing CO<sub>2</sub>RR efficiency *via* engineering substrate–cluster interactions.

## 2. Computational methods

Spin-polarized density functional theory (DFT) calculations were carried out using the Vienna ab initio simulation package (VASP).<sup>38,39</sup> The projector-augmented-wave (PAW) method was employed to treat the core wave functions.<sup>40</sup> The generalized gradient approximation (GGA) in the Perdew–Burke–Ernzerhof (PBE) form is adopted.<sup>41,42</sup> Long-range van der Waals (vdW) interaction was corrected using the DFT-D3 scheme,<sup>43</sup> and a vacuum space exceeding 20 Å was used to minimize periodic interactions. The 3 × 3 × 1 Monkhorst–Pack *k*-points in the Brillouin zone are sampled for structural optimizations, and

dense  $6 \times 6 \times 1$   $k$ -meshes are set for the density of states (DOS) calculations for T'-WTe<sub>2</sub>.  $15 \text{ \AA} \times 15 \text{ \AA} \times 15 \text{ \AA}$  cubic cells are used to optimize the isolated Cu<sub>3</sub>, Cu<sub>8</sub> and Cu<sub>13</sub> clusters before loading on the WTe<sub>2</sub> surfaces. The cutoff energy for the plane wave basis is 400 eV in all the calculations, and the energy and force convergence criterion are respectively set to  $10^{-5}$  eV and  $10^{-2}$  eV  $\text{\AA}^{-1}$ . We used VASPsol for the implicit solvation calculations.<sup>44</sup> Water is considered as the continuum solvent throughout, with a bulk static dielectric constant  $\epsilon_s$  of 80.<sup>45</sup> In addition, canonical *ab initio* molecular dynamics simulations (AIMDs) with a Nosé thermostat and integrating time with the Verlet algorithm at a time step of 1 fs are employed to investigate the thermodynamic stability of the catalyst.<sup>46</sup>

The isolated CO<sub>2</sub> molecule is simulated in a large cubic cell of 15  $\text{\AA}$  in length. The adsorption energies are calculated according to the equation  $E_{\text{ads}} = E_{\text{adsorbed-system}} - E_{\text{molecule}} - E_{\text{catalyst}}$ , where  $E_{\text{adsorbed-system}}$ ,  $E_{\text{molecule}}$ , and  $E_{\text{catalyst}}$  are the total energies of the catalyst with CO<sub>2</sub>\*, the isolates CO<sub>2</sub> molecule and Cu<sub>*n*</sub>@WTe<sub>2</sub> ( $n = 3, 8, 13$ ), respectively. The Bader charge, charge density difference, and DOS are calculated to clarify the interactions between the adsorbed molecule and the catalyst surface. To calculate the free energy profiles of the electrocatalytic CO<sub>2</sub>RR, the computational electrode model (CHE) is employed.<sup>47</sup> The free energy change ( $\Delta G$ ) at each elementary step of the CO<sub>2</sub>RR process is calculated using the equation  $\Delta G = \Delta E + \Delta ZPE - T\Delta S$ , where  $\Delta E$  is the total energy change

calculated by DFT,  $\Delta ZPE$  is the zero-point energy correction through frequency analysis, and  $T$  and  $\Delta S$  are the reaction temperature ( $T = 298.15$  K) and the entropy value change, respectively. The limiting potential ( $U_L$ ) is defined as the maximum free energy change using the relation  $U_L = -\Delta G_{\text{PDS}}/e$ , where  $\Delta G_{\text{PDS}}$  is the maximum free energy increase in a potential determining step (PDS). In addition, we utilized the post-processing functionalities provided by qvasp and VASPKIT to analyze the computational results.<sup>48</sup>

For isolated Cu<sub>*n*</sub> clusters, our calculations show finite magnetic moments ( $1\mu_B$  for Cu<sub>3</sub>,  $0\mu_B$  for Cu<sub>8</sub>, and  $5\mu_B$  for Cu<sub>13</sub>), in line with previous data.<sup>49,50</sup> However, when supported on the T'-WTe<sub>2</sub> substrate, the whole system becomes nonmagnetic. The charge transfer between the clusters and substrate fully quenches the magnetism.

### 3. Results and discussion

#### 3.1. Structural models of Cu<sub>*n*</sub> ( $n = 3, 8, 13$ ) clusters, CO<sub>2</sub> adsorption on Cu<sub>*n*</sub> and CO<sub>2</sub>RR on Cu<sub>*n*</sub>

The most stable structures of Cu<sub>3</sub>, Cu<sub>8</sub>, and Cu<sub>13</sub> are an equilateral triangle geometry with  $C_{2v}$  symmetry,<sup>34</sup> a tetragonal crystal with  $D_{2d}$  symmetry,<sup>36</sup> and an icosahedron geometry with  $I_h$  symmetry (see Fig. 1a–c),<sup>35,51</sup> respectively. The calculated Cu–Cu bond lengths ( $L_{\text{Cu–Cu}}$ ) are 2.34  $\text{\AA}$  for Cu<sub>3</sub>, 2.30–2.50  $\text{\AA}$  for Cu<sub>8</sub>, and 2.53  $\text{\AA}$  for Cu<sub>13</sub>, which agree well with previously reported values.<sup>36,49,50,52</sup>

We first examine CO<sub>2</sub> adsorption on Cu<sub>*n*</sub> ( $n = 3, 8, 13$ ) clusters. The most stable adsorption configurations are depicted in Fig. 1d–f, revealing a bent CO<sub>2</sub> geometry on all Cu<sub>*n*</sub> clusters, which indicates effective activation of the CO<sub>2</sub> molecule. For the CO<sub>2</sub>RR, CH<sub>4</sub> is the sole product across all cluster sizes; however, the potential-determining step (PDS) varies with cluster size, and the overpotential increases as the cluster size grows (see Table 1). The calculated free energy profile and the corresponding reaction intermediates along the most favorable CO<sub>2</sub>RR pathway are provided in the ESI† (see Fig. S1 and S2). Additionally, we further investigate the HER on the Cu<sub>*n*</sub> cluster (Fig. 1g–i). A comparison of  $U_L$  between CO<sub>2</sub>RR and HER, presented in Table 1, shows that the HER suppresses the CO<sub>2</sub>RR on all pure Cu<sub>*n*</sub> clusters (see Fig. S13, ESI†).

#### 3.2. Geometric structures of T'-WTe<sub>2</sub>

To investigate whether substrate selection can enhance CO<sub>2</sub>RR performance, we build on our prior findings identifying T'-WTe<sub>2</sub> as an effective substrate that could interact with clusters

Fig. 1 (a)–(c) Structures of the pristine Cu<sub>3</sub>, Cu<sub>8</sub> and Cu<sub>13</sub> clusters. (d)–(f) The most stable adsorption configurations for CO<sub>2</sub> on Cu<sub>3</sub>, Cu<sub>8</sub>, and Cu<sub>13</sub> clusters. (g)–(i) The optimized configurations for H adsorption on Cu<sub>3</sub>, Cu<sub>8</sub>, and Cu<sub>13</sub>.

Table 1 Calculated PDS and  $U_L$  and the final product of the CO<sub>2</sub>RR with Cu<sub>*n*</sub> ( $n = 3, 8, 13$ ) catalysts in contrast to the HER

Configurations	CO <sub>2</sub> RR			HER $U_L$ (V)
	PDS	$U_L$ (V)	Product	
Cu <sub>3</sub>	*CO + e <sup>−</sup> + H <sup>+</sup> → *CHO	0.64	CH <sub>4</sub>	−0.51
Cu <sub>8</sub>	*OCHOH + e <sup>−</sup> + H <sup>+</sup> → *CHO + H <sub>2</sub> O	0.85	CH <sub>4</sub>	0.73
Cu <sub>13</sub>	*CO + e <sup>−</sup> + H <sup>+</sup> → *CHO	0.89	CH <sub>4</sub>	−0.14

Fig. 2 (a) Schematic of the  $3 \times 2$  supercell of  $T'$ -WTe<sub>2</sub>. W and Te atoms are denoted by grey and orange spheres, respectively. (b) Band structure for the  $T'$ -WTe<sub>2</sub> monolayer.

sufficiently.<sup>30,53</sup> Consequently, we selected  $T'$ -WTe<sub>2</sub> as the substrate for loading clusters to further evaluate its CO<sub>2</sub>RR properties.

The monoclinic metal  $T'$  phase of WTe<sub>2</sub>, a semimetal with no band gap (Fig. 2b), was synthesized decades ago (Fig. 2a),<sup>32</sup> a characteristic corroborated by the calculated partial density of states (PDOS) in Fig. S6 (ESI<sup>†</sup>).  $T'$ -WTe<sub>2</sub> features three atomic layers, with nonequivalent top (Te<sub>1</sub> and Te<sub>2</sub>) and bottom (Te<sub>3</sub> and Te<sub>4</sub>) Te layers. The Te<sub>1</sub> atom sits higher than Te<sub>2</sub> in

the top layer, forming what we term as a 'nonuniform surface',<sup>33</sup> with bond lengths of 2.72 Å ( $L_{Te_2-W}$ ) and 2.83 Å ( $L_{Te_1-W}$ ).

### 3.3. CO<sub>2</sub> adsorption and electroreduction for Cu<sub>n</sub>@ $T'$ -WTe<sub>2</sub> ( $n = 3, 8, 13$ )

Firstly, we investigate the adsorption of Cu<sub>n</sub> ( $n = 3, 8, 13$ ) clusters on the  $T'$ -WTe<sub>2</sub> substrate, with all optimized configurations presented in Fig. S3–S5 (ESI<sup>†</sup>). The most stable structures for Cu<sub>3</sub>@ $T'$ -WTe<sub>2</sub> (Fig. S3b, ESI<sup>†</sup>), Cu<sub>8</sub>@ $T'$ -WTe<sub>2</sub> (Fig. S4h, ESI<sup>†</sup>), and Cu<sub>13</sub>@ $T'$ -WTe<sub>2</sub> (Fig. S5d, ESI<sup>†</sup>) are highlighted, in Fig. 3 for further studying the CO<sub>2</sub>RR. Bader charge analysis (Table S1, ESI<sup>†</sup>) reveals electron transfers of 0.28e, 0.32e and 0.18e from Cu<sub>3</sub>, Cu<sub>8</sub>, and Cu<sub>13</sub> to  $T'$ -WTe<sub>2</sub>, respectively, indicating significant substrate–cluster interactions, further evidenced by orbital hybridization in the PDOS (Fig. S7, ESI<sup>†</sup>). As noted in Section 2, while isolated Cu<sub>n</sub> clusters exhibit size-dependent magnetism, the interaction with the  $T'$ -WTe<sub>2</sub> substrate leads to complete spin quenching. The AIMD simulation at 500 K over 5ps (Fig. S11, ESI<sup>†</sup>) shows no structural degradation, confirming the excellent thermal stability of the Cu<sub>n</sub>@ $T'$ -WTe<sub>2</sub> catalyst under ambient conditions.

To assess the substrate's role in the CO<sub>2</sub>RR performance, we studied CO<sub>2</sub> adsorption on the Cu<sub>3</sub>@ $T'$ -WTe<sub>2</sub>, Cu<sub>8</sub>@ $T'$ -WTe<sub>2</sub>, and Cu<sub>13</sub>@ $T'$ -WTe<sub>2</sub> surfaces. Various adsorption configurations of CO<sub>2</sub> on the catalyst surfaces are considered as shown in Fig. S8 (ESI<sup>†</sup>). Strong adsorption energy typically elongates the C–O bond length in the adsorbed CO<sub>2</sub> molecule.<sup>17,54,55</sup> Fig. 3 presents the most favorable sites for CO<sub>2</sub> adsorption, showing  $L_{C-O}$  extended to 1.22 Å and 1.88 Å (Fig. 3a), 1.25 Å and 1.28 Å (Fig. 3d), and 1.26 Å (Fig. 3g) for the Cu<sub>3</sub>@ $T'$ -WTe<sub>2</sub>,

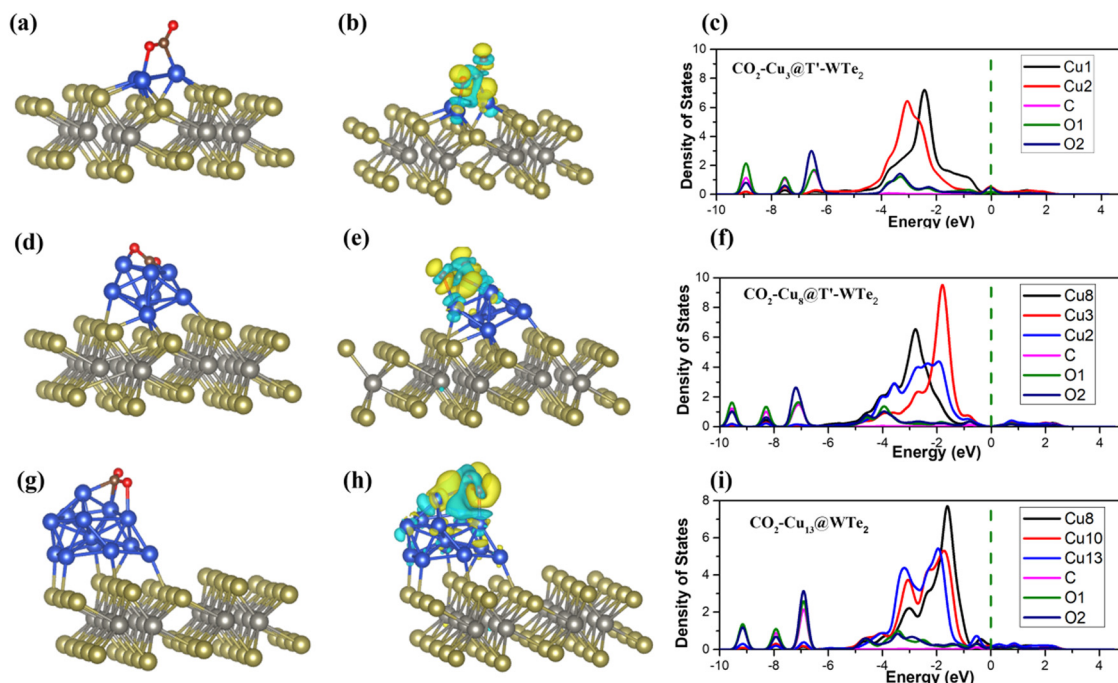

Fig. 3 The most stable adsorption configurations, the isosurface of the charge density difference with an isovalue of  $0.003 \text{ \AA}^{-3}$ , and the PDOS for CO<sub>2</sub> on Cu<sub>3</sub>@WTe<sub>2</sub>: (a)–(c), Cu<sub>8</sub>@WTe<sub>2</sub> (d)–(f) and Cu<sub>13</sub>@WTe<sub>2</sub> (g)–(i). The blue (yellow) wireframes denote the loss (gain) of electrons with the isosurface values set as  $0.003 \text{ \AA}^{-3}$ . The Fermi level is assigned at 0 eV.

**Table 2** Parameters of adsorbed CO<sub>2</sub> on the Cu<sub>n</sub>@WTe<sub>2</sub> (*n* = 3, 8, 13). Including adsorption free energies (*E*<sub>ads-free</sub>), O=C=O angles (*∠*OCO), the corresponding C=O bond lengths (*L*<sub>C=O</sub>) of Cu<sub>n</sub>@WTe<sub>2</sub> (*n* = 3, 8, 13), and the net charge transferred from adsorbents to CO<sub>2</sub> ( $\Delta q$  is calculated based on the Bader charges)

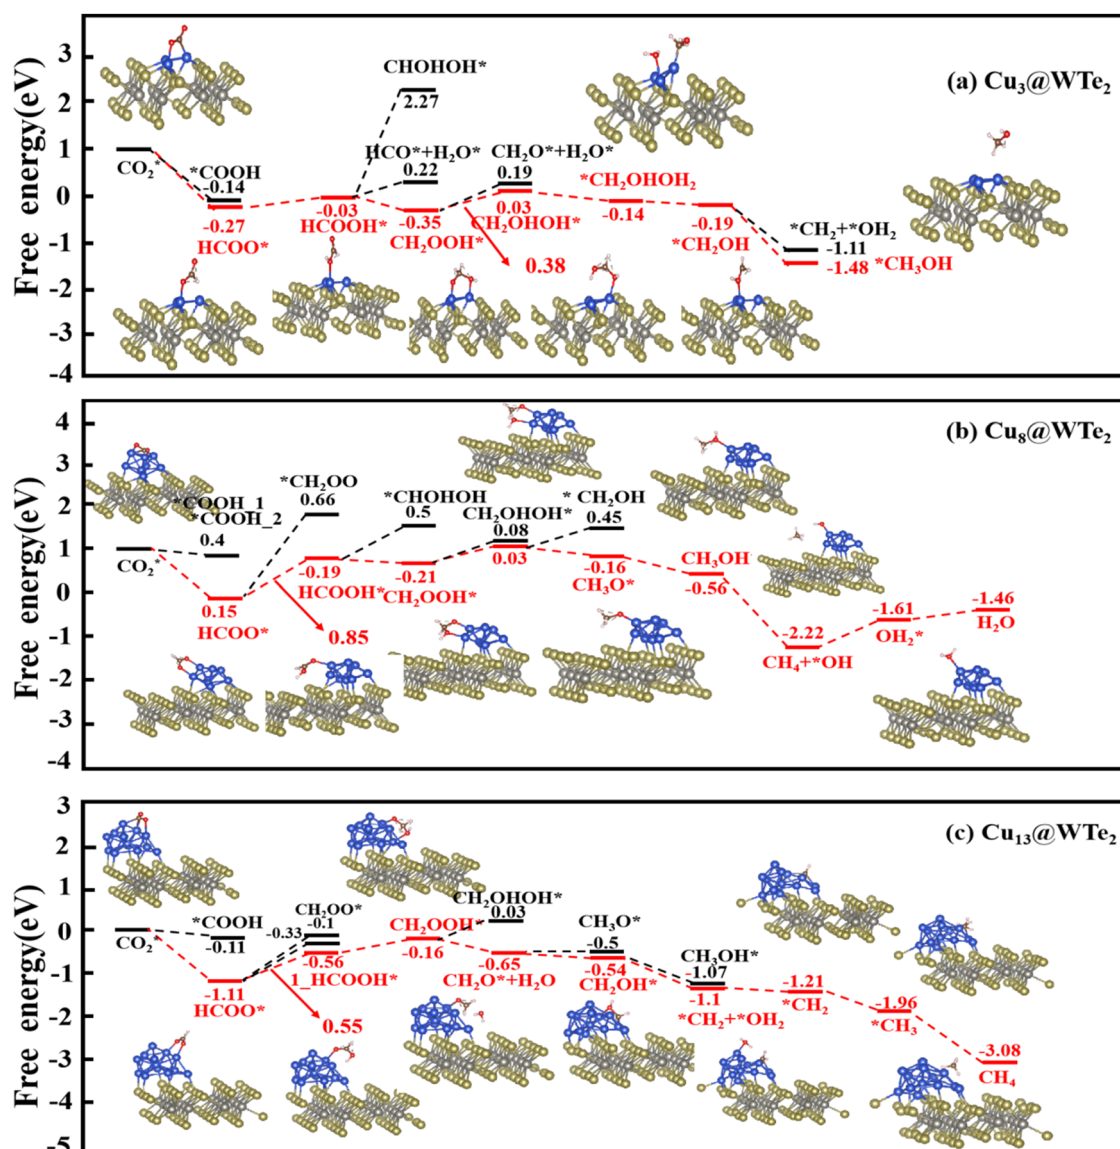

Adsorption configurations	<i>E</i> <sub>ads-free</sub> (eV)	<i>∠</i> OCO	<i>L</i> <sub>C=O</sub> (Å)	$\Delta q$ (e)
CO <sub>2</sub> -Cu <sub>3</sub> @WTe <sub>2</sub>	-0.10	134.2°	1.22; 1.28	0.62
CO <sub>2</sub> -Cu <sub>8</sub> @WTe <sub>2</sub>	-0.33	130.6°	1.25; 1.28	0.79
CO <sub>2</sub> -Cu <sub>13</sub> @WTe <sub>2</sub>	0.02	132.3°	1.26	0.74

Cu<sub>8</sub>@T'-WTe<sub>2</sub> and Cu<sub>13</sub>@T'-WTe<sub>2</sub> systems, respectively, suggesting enhanced activation of CO<sub>2</sub>. After CO<sub>2</sub> adsorption, the linear O=C=O geometry bends into a V-shape, with the (*∠*OCO angles decreasing from 179.9° to 134.2° for Cu<sub>3</sub>@WTe<sub>2</sub>) (Table 2). Similarly, the same trend can be observed for Cu<sub>8</sub>@WTe<sub>2</sub> and Cu<sub>13</sub>@WTe<sub>2</sub>, indicating effective CO<sub>2</sub> activation by Cu<sub>n</sub>@WTe<sub>2</sub>. The PDOS analysis shown in Fig. 3c, f, and i

reveals orbital hybridization and charge transfer between Cu, C, and O atoms, underscoring the strong interaction between the CO<sub>2</sub> molecules and the Cu<sub>n</sub>@T'-WTe<sub>2</sub> catalysts.<sup>11,56,57</sup> The charge density difference (see Fig. 3) and the Bader charge analysis (Table 2) further confirm electron donation from Cu<sub>n</sub>@WTe<sub>2</sub> to the CO<sub>2</sub> molecule (around 0.62e–0.79e). The broadly dispersed PDOS peaks for C and O relative to isolated CO<sub>2</sub> molecules (Fig. S9, ESI†) and the hybridization with Cu atoms also support the strong interaction between CO<sub>2</sub> and Cu<sub>n</sub>.

### 3.4. CO<sub>2</sub> reduction reaction pathways on the Cu<sub>n</sub>@WTe<sub>2</sub> (*n* = 3, 8, 13)

We next explore the CO<sub>2</sub>RR pathways on Cu<sub>n</sub>@WTe<sub>2</sub>. Fig. 4 illustrates the calculated free energy profile for the most favorable CO<sub>2</sub>RR pathways on Cu<sub>3</sub>@WTe<sub>2</sub>, Cu<sub>8</sub>@WTe<sub>2</sub>, and Cu<sub>13</sub>@WTe<sub>2</sub>, with the corresponding optimal reaction configurations shown in Fig. S10 (ESI†). For CO<sub>2</sub>-Cu<sub>3</sub>@WTe<sub>2</sub>, the

**Fig. 4** Free energy diagram for the electrochemical CO<sub>2</sub>RR on (a) Cu<sub>3</sub>@WTe<sub>2</sub>, (b) Cu<sub>8</sub>@WTe<sub>2</sub>, and (c) Cu<sub>13</sub>@WTe<sub>2</sub>.

**Table 3** The calculated  $U_L$  ( $|U_L|$ ), HCOO intermediate adsorption ( $\Delta G_{\text{HCOO}}^*$ ) and final product of CO<sub>2</sub>RR, and the H\* intermediate adsorption ( $\Delta G_{\text{H}}^*$ ) of the HER with Cu<sub>n</sub>@WTe<sub>2</sub> ( $n = 3, 8, 13$ ) catalysts

Configurations	CO <sub>2</sub> RR			HER	
	$ U_L $ (V)	$\Delta G_{\text{HCOO}}^*$ (eV)	Product	$ U_L $ (V)	$\Delta G_{\text{H}}^*$ (eV)
Cu <sub>3</sub> @WTe <sub>2</sub>	0.38	−0.27	CH <sub>3</sub> OH	0.10	0.10
Cu <sub>8</sub> @WTe <sub>2</sub>	0.86	−1.04	CH <sub>4</sub>	0.05	−0.05
Cu <sub>13</sub> @WTe <sub>2</sub>	0.55	−1.11	CH <sub>4</sub>	0.85	−0.85

initial H<sup>+</sup> and e<sup>−</sup> pair attacks the carbon atom of CO<sub>2</sub>, forming HCOO\* with a free energy change of −0.27 eV. Subsequent hydrogenation yields HCOOH\*, followed by an exothermic step forming CH<sub>2</sub>OOH\* as shown in Fig. 4a, which is energetically more preferred than the formation of CHOH\* or HCO\* + H<sub>2</sub>O\*. Further hydrogenation of CH<sub>2</sub>OOH\* favors CH<sub>2</sub>OH\* ( $\Delta G < 0$ ) over CH<sub>2</sub>O\* + H<sub>2</sub>O\*. Two subsequent additions of the H<sup>+</sup> and e<sup>−</sup> pair will attack the O atom, releasing the H<sub>2</sub>O molecule and leaving \*CH<sub>2</sub>OH, which undergoes successive hydrogenation steps to produce CH<sub>3</sub>OH molecules. Overall, the PDS is the formation of CH<sub>2</sub>OH\* from CH<sub>2</sub>OOH\* with a  $U_L$  of −0.38 V.

For the Cu<sub>8</sub>@WTe<sub>2</sub> and Cu<sub>13</sub>@WTe<sub>2</sub> surface, the initial step of the CO<sub>2</sub>RR is the formation of HCOO\*, followed by hydrogenation of HCOO\* to form HCOOH\* (see Fig. 4b and c), which is more energetically favorable than that of CH<sub>2</sub>OOH\*. HCOOH\* then converts to CH<sub>2</sub>OOH\*. On Cu<sub>8</sub>@WTe<sub>2</sub>, CH<sub>2</sub>OOH\* after hydrogenation will transform into CH<sub>2</sub>O\* + \*OH<sub>2</sub>, proceeding to CH<sub>3</sub>OH\* and ultimately producing CH<sub>4</sub>. On Cu<sub>13</sub>@WTe<sub>2</sub>, CH<sub>2</sub>OOH will be further hydrogenated to CH<sub>2</sub>O\* with H<sub>2</sub>O release, followed by hydrogenation to \*CH<sub>4</sub> with the final release of the CH<sub>4</sub> molecule. The PDS for both the Cu<sub>8</sub>@WTe<sub>2</sub> and Cu<sub>13</sub>@WTe<sub>2</sub> systems is HCOO\* → HCOOH\*, with  $U_L$  values of −0.85 V and −0.55 V, respectively. The free energy values ( $G(T)$ ) for these pathways are detailed in Table S3 (ESI†).

The analysis reveals that Cu<sub>3</sub>@WTe<sub>2</sub>, Cu<sub>8</sub>@WTe<sub>2</sub>, and Cu<sub>13</sub>@WTe<sub>2</sub> all exhibit robust CO<sub>2</sub>RR activity. On Cu<sub>3</sub>@WTe<sub>2</sub>, CO<sub>2</sub>RR proceeds *via* a 6e<sup>−</sup> charge transfer pathway, yielding CH<sub>3</sub>OH, whereas Cu<sub>8</sub>@WTe<sub>2</sub> and Cu<sub>13</sub>@WTe<sub>2</sub> favor an 8e<sup>−</sup> charge transfer reaction pathway, producing CH<sub>4</sub> as the primary product. Comparison of the overpotentials with pure Cu<sub>n</sub> clusters (Table S2, ESI†) shows that Cu<sub>n</sub> on the T'-WTe<sub>2</sub> substrate outperforms their standalone counterparts, with lower  $|U_L|$  values indicating enhanced CO<sub>2</sub>RR efficiency. Specifically,  $|U_L|$  for Cu<sub>3</sub>@WTe<sub>2</sub> is 0.38 V (vs. 0.64 V for pure Cu<sub>3</sub>, a 0.26 V reduction), while  $|U_L|$  for Cu<sub>13</sub>@WTe<sub>2</sub> is 0.55 V (vs. 0.89 V for pure Cu<sub>13</sub>, a 0.34 V reduction). This suggests that the T'-WTe<sub>2</sub> substrate significantly boosts the CO<sub>2</sub>RR performance, with the enhancement scaling with Cu cluster size.

### 3.5. Analysis of the hydrogen evolution reaction and solvent effects

To evaluate the competing HER,<sup>18</sup> we analyzed the HER performance on Cu<sub>n</sub>@WTe<sub>2</sub> ( $n = 3, 8, 13$ ), as detailed in Fig S12 and S14 (ESI†). In all the optimized configurations, H atoms preferentially bind to Cu clusters rather than the WTe<sub>2</sub> surface.

Catalytic selectivity was assessed using the difference in  $U_L$  values, *i.e.*,  $|U_{\text{L}(\text{CO}_2)}| - |U_{\text{L}(\text{H}_2)}|$ ,<sup>37</sup> where a positive value of  $|U_{\text{L}(\text{CO}_2)}| - |U_{\text{L}(\text{H}_2)}|$  indicates a poor CO<sub>2</sub>RR selectivity over the HER. For the Cu<sub>13</sub>@T'-WTe<sub>2</sub>, the  $|U_{\text{L}(\text{CO}_2)}| - |U_{\text{L}(\text{H}_2)}|$  is calculated to be −0.30 V (see Table 3), suggesting a better CO<sub>2</sub>RR selectivity over the HER. Given that HCOO\* is a critical intermediate in all CO<sub>2</sub>RR pathways, we then considered the competition between H\* and HCOO\*.<sup>55,58–60</sup> For the Cu<sub>13</sub>@WTe<sub>2</sub>, HCOO\* formation (Fig. 4c) has a free energy change of −1.11 eV, more favorable than −0.85 eV for the HER process (see Table 3), indicating greater HCOO\* stability over H\*.

To further gain an in-depth understanding of the catalyst effects, we compared the DOS curves of isolated and adsorbed HCOO\* intermediates on the catalyst. As shown in Fig S15 (ESI†), the 2p orbitals of O and C atoms after adsorption shift toward lower energy region near the Fermi level, with larger shifts reflecting stronger intermediate–substrate interaction, and the lower adsorption energy.<sup>17,61,62</sup> Cu<sub>13</sub>@WTe<sub>2</sub> exhibits the lowest adsorption energy (−1.11 eV) compared to −0.27 eV for Cu<sub>3</sub>@WTe<sub>2</sub>. This suggests that the buckled T'-WTe<sub>2</sub> surface enhances CO<sub>2</sub>RR activity in the supported Cu<sub>n</sub> nanocluster, with larger cluster size strengthening substrate–Cu interactions and boosting electrocatalytic CO<sub>2</sub> reduction.

Overall, Cu<sub>13</sub>@WTe<sub>2</sub> emerges as the optimal CO<sub>2</sub>RR electrocatalyst among the studied configurations. We further examine its electrochemical CO<sub>2</sub>RR performance using free energy diagrams with an implicit solvation model (Fig. S16, ESI†). The PDS remains unchanged, with the  $U_L$  value shifting by only 0.09 V upon incorporating the solvation effect. These findings suggest that the electrolyte environment exerts minimal influence on the CO<sub>2</sub>RR performance of the Cu<sub>13</sub>@WTe<sub>2</sub> catalysts.

## 4. Conclusions

In conclusion, we theoretically investigate the CO<sub>2</sub> electrocatalytic properties on pure Cu clusters and their performance when supported on a T'-WTe<sub>2</sub> substrate. Our results reveal that the introduction of the WTe<sub>2</sub> substrate significantly reduces the CO<sub>2</sub>RR overpotential across the system, with Cu<sub>13</sub>@WTe<sub>2</sub> exhibiting particularly notable suppression of the competing hydrogen evolution reaction (HER). Our findings elucidate the size-dependent electrocatalytic behavior of the CO<sub>2</sub>RR and HER across different Cu clusters while highlighting the critical role of the substrate in modulating electrochemical performance. Collectively, this work offers valuable insights and a strategic framework for designing efficient CO<sub>2</sub>RR catalysts, paving the way for future experimental advancement in electrocatalytic systems.
