# Catalysis activity and chemoselectivity control with the *trans* ligand in Ru-H pincer complexes†

Mita Halder, Diana Castillo Cardenas, D‡ Angela M. Chartouni Damien B. Culver \*

(PhPN<sup>H</sup>P)Ru(H)(Cl)(CO) serves as a precatalyst to a variety of important catalytic transformations but most improvements have been restricted to the replacement of the CO ligand cis to the hydride or changing the Ph groups of the pincer for other aryl or alkyl groups. The ligand trans to the hydride is often another hydride and studies that utilize other trans ligands in catalysis are limited. In this work, we synthesized a series of  $(PhPN^HP)Ru(H)(CO)(L)[BPh_4]$  complexes bearing isonitrile,  $PMe_3$ , or a N-heterocyclic ligand trans to the Ru–H. We compared the new complexes abilities to catalyze the transfer hydrogenation of ketones. We found that all the trans ligands improved the chemoselectivity and stability of the catalysts; and strong  $\pi$ -accepting ligands resulted in poor catalytic activities whereas strong  $\sigma$ -donating ligands accelerated the catalysis.

## Introduction

Inorganic pincer complexes catalyze a variety of organic transformations, often exhibiting high activities and selectivities. 1-7 (PhPNHP)Ru(H)(Cl)(CO) (also known as Ru-MACHO)8 and similar analogues serve as precatalysts or catalysts for hydrogenation, transfer hydrogenation, dehydrogenative coupling of coupling, alcohols, aldehyde and other transformations.9-15 In all of these reports, the active catalysts are neutral and the ligand trans to the active hydride is another hydride (Fig. 1). Some reports have described (RPN<sup>H</sup>P) Ru(X)2(L) complexes bearing phosphines, N-heterocyclic carbenes, and other ligands cis to the Ru-H instead of CO, or with other R groups on the pincer ligand showing that the ligand choice has a strong effect on the complex's reactivity. 16-20 However, there has been limited work into the formation of active catalysts with ancillary ligands trans to the hydride. A method to further examine the effects of ligands trans to the hydride is formation of [(RPN<sup>H</sup>P)Ru(H)(L)<sub>2</sub>]<sup>+</sup> ions which allows for straight forward installation of dative ligands with tunable electronic and steric environments.

Reported examples of monomeric  $[(RPN^HP)Ru(X)(L)_2]^+$  ions (X = H or halide) are limited. Rozenel and Arnold showed that cationic  $[(i^1PPN^HP)Ru(Cl)(L)]^+_2$  dimers can be broken into

the best of our knowledge, a systematic evaluation of the trans ligand influence on the Ru-H in Ru-MACHO derivatives for catalysis has not been previously performed. In this work, we synthesized a series of [(PhPNHP)Ru(H)(L)(CO)]+ complexes bearing phosphine, isonitrile and N-heterocyclic ligands and compared their carbonyl transfer hydrogenation activities with neutral Ru-MACHO to determine the effects of dative ligands trans to the hydride.

## **Experimental**

#### **General considerations**

All procedures were executed under an inert atmosphere of nitrogen or argon utilizing standard Schlenk line or glovebox techniques. THF- $d_8$  and Benzene- $d_6$  were purchased from Cambridge Isotope laboratories. Benzene- $d_6$  was dried over sodium/benzophenone, degassed by three successive freezepump-thaw cycles, distilled under vacuum, and stored over 4 Å molecular sieves inside an inert atmosphere glovebox prior to use. THF-d<sub>8</sub> was dried over 4 Å molecular sieves and stored inside an inert atmosphere glovebox prior to use. Anhydrous and degassed solvents were purchased from Sigma Aldrich and stored over 3 or 4 Å molecular sieves prior to use. 1,3,5-Trimethoxybenzene, benzophenone, 4-bromoacetophenone, and 4-methoxyacetophenone were purified by sublimation under vacuum and stored in a glovebox prior to use. Acetophenone was dried over CaH2 followed by distillation under vacuum. (PhPNHP)Ru(H)(Cl)(CO) (1) was purchased from Strem chemicals or Sigma Aldrich and purified prior to use as described in the ESI.† All other commercially available reagents were used as received without further purification.

NMR analyses were performed on a Bruker Avance III 600 MHz spectrometer, or a Varian MR-400 MHz spectrometer housed by the Iowa State University Chemical Instrumentation Facility (CIF). All NMR spectra were obtained at 25 °C unless otherwise specified. All <sup>1</sup>H NMR spectra were referenced to the solvent residual signal(s). 13C{1H} NMR spectra were referenced to a solvent signal. All carbon NMR assignments are singlets unless noted otherwise. The 31P NMR spectra were externally referenced to 85% H<sub>3</sub>PO<sub>4</sub> (0.0 ppm). Fourier transform infrared (FTIR) spectra were measured on a Bruker ALPHA II spectrometer contained within an argon filled glovebox. Samples for transmission IR were diluted with KBr and pressed into a transparent pellet using a hand press to make a pellet. Elemental analyses were performed on a Thermo FlashSmart 2000 CHNS/O Combustion Elemental Analyzer housed by the Iowa State University CIF. Single crystal diffraction data was collected using a Bruker D8 VENTURE diffractometer using MoK $\alpha$  ( $\lambda$  = 0.71073) in the ISU CIF.

#### Synthesis of complexes 2a-d, 3, and 4

 $[(PhPN^{H}P)Ru(H)(CNCy)(CO)][BPh_{4}]$  (2a): In a 25 mL Schlenk tube, 1 (100.0 mg, 0.165 mmol) in 10 mL tetrahydrofuran (THF) was stirred at 65 °C until complete dissolution. Then CyNC (22.5 μL, 0.181 mmol) was added and the reaction was

stirred at 65 °C for 10 h. NaBPh<sub>4</sub> (56.4 mg, 0.165 mmol) was added and after 1 h of additional stirring at 65 °C, the mixture was cooled to room temperature, filtered through Celite and concentrated to 5 mL under reduced pressure. A layer of pentane (5 mL) was added, and the solution was kept overnight at room temperature resulting in 89.0 mg of a colorless needle shaped microcrystalline product. The product was isolated by filtration, washed with pentane and finally dried under vacuum. The mother liquor was reduced to 2 mL and further recrystallized using pentane (2 mL) furnishing another 36.0 mg of the microcrystalline product. Total yield of 2a was 125.0 mg (76%). <sup>1</sup>H NMR (THF- $d_8$ , 25 °C, 600 MHz):  $\delta$ 7.88-7.85 (m, 4H, PhH), 7.67-7.64 (m, 4H, PhH), 7.51-7.44 (m, 12H, Ph**H**), 7.32 (bs, 8H, Ph**H** in BPh<sub>4</sub>), 6.86 (t,  ${}^{3}J_{HH}$  = 7.4 Hz, 8H, Ph**H** in BPh<sub>4</sub>), 6.71 (t,  ${}^{3}J_{HH}$  = 7.2 Hz, 4H, Ph**H** in BPh<sub>4</sub>), 3.75-3.71 (m, 1H, CH<sub>2</sub>NHCH<sub>2</sub>), 3.35 (m, 1H, ipso H in Cyclohexane), 2.94-2.85 (m, 2H, NCH<sub>2</sub>CH<sub>2</sub>P), 2.81-2.77 (m, 2H, NCH<sub>2</sub>CH<sub>2</sub>P), 2.19 (td,  ${}^{2}J_{PH} = 14.5$ ,  ${}^{3}J_{HH} = 4.6$  Hz, 2H, NCH<sub>2</sub>CH<sub>2</sub>P), 2.14-2.08 (m, 2H, NCH<sub>2</sub>CH<sub>2</sub>P), 1.38-1.28 (m, 5H, Cyclohexyl CH<sub>2</sub>), 1.14-0.97 (m, 5H, Cyclohexyl CH<sub>2</sub>), -7.65 (t,  $^{2}J_{PH}$  = 17.01 Hz, 1H, Ru-H) ppm.  $^{31}P\{^{1}H\}$  NMR (THF- $d_{8}$ , 25 °C, 242.9 MHz): 57.5 (s, Ru-P) ppm. <sup>13</sup>C{<sup>1</sup>H} NMR (THF-d<sub>8</sub>, 25 °C, **150.9 MHz):** 203.8 (Ru–CO, identified by HMBC), 165.4 (q,  ${}^{1}J_{CB}$ = 49.3 Hz, C<sub>i</sub> of BPh<sub>4</sub>), 147.6 (Ru-CNR, identified by HMBC), 137.4 (bs, ortho C of BPh<sub>4</sub>), 137.3 (t,  ${}^{1}J_{PC}$  = 22.6 Hz, P-Ph, C<sub>i</sub>), 135.9 (t,  ${}^{1}J_{PC}$  = 22.6 Hz, PPh, C<sub>i</sub>), 134.1 (t,  ${}^{2}J_{PC}$  = 6.8 Hz, PPh), 132.8 (t,  ${}^{2}J_{PC}$  = 6 Hz, PPh), 131.7, 131.4, 130 (t,  ${}^{3}J_{PC}$  = 4.5 Hz, PPh), 129.7 (t,  ${}^{3}J_{PC}$  = 5.3 Hz, PPh), 126.1 (q,  ${}^{3}J_{CB}$  = 3 Hz, meta C of BPh<sub>4</sub>), 122.2 (bs, para C of BPh<sub>4</sub>), 55.3 (CHNC), 54.8  $(PCH_2CH_2N)$ , 33.9 (t,  ${}^{1}J_{PC} = 13.6$  Hz,  $NCH_2CH_2P$ ), 33.1, 23.7 ppm. #### General procedure for the transfer hydrogenation catalysis

In an NMR tube, ketone (0.15 mmol), catalyst (stock solution in THF), KO $^{t}$ Bu (stock solution in THF), a benzene- $d_{6}$  capillary and  $^{i}$ PrOH (0.4 mL), were added under nitrogen atmosphere and then heated at 80 °C for the specified period. Afterwards, the reaction mixture was cooled to room temperature. 1,3,5-Trimethoxybenzene was added to the reaction mixture as an internal standard and the reactions were analyzed by  $^{1}$ H NMR spectroscopy. The reaction conditions for Tables 1 and 2 in the main text were chosen based on conditions optimized with 2a for benzophenone reduction as shown in Table S1.† Representative time course NMR measurements for benzophenone transfer hydrogenation are provided in Fig. S2–S6† for 1, 2a, 2d, 3 and 4.

#### Catalysis in the presence of excess ligand

Five equiv. of ligand. A mixture of benzophenone (0.15 mmol), 2a or 3 (0.15 µmol, 0.1 mol%), KO $^t$ Bu (0.94 µmol, 0.625 mol%), ligand (0.75 µmol, CNCy for 2a or PMe $_3$  for 3),  $^i$ PrOH (0.4 mL), and THF- $d_8$  (0.15 mL) in an NMR tube was heated at 80 °C for the indicated time in Table 3 then analyzed by NMR spectroscopy.

One equiv. of PMe<sub>3</sub>. A mixture of 3 (3  $\mu$ mol, 2 mol%), KO<sup>t</sup>Bu (7.5  $\mu$ mol, 5 mol%), <sup>i</sup>PrOH (0.4 mL), PMe<sub>3</sub> (3  $\mu$ mol) and THF- $d_8$  (0.15 mL) in an NMR tube was heated for 10 min at 80 °C. Then benzophenone (0.15 mmol) was added, and the tube was heated at 80 °C for an additional 30 min then analyzed by NMR spectroscopy.

Attempt to generate catalyst 3 *in situ*. A mixture of 1 (0.75  $\mu$ mol, 1 equiv.), PMe<sub>3</sub> (0.75  $\mu$ mol, 1 equiv.), NaBPh<sub>4</sub> (0.75  $\mu$ mol, 1 equiv.) in THF- $d_8$  were combined in an NMR tube and occasionally sonicated for 30 minutes at room temperature. Then benzophenone (0.25 mmol), KO<sup>t</sup>Bu (1.6  $\mu$ mol) and <sup>i</sup>PrOH (0.4 mL) were added to that tube. After sonication for 5 minutes at room temperature the tube was heated at

80 °C for the indicated time in Table 3 and progress of the reaction was monitored by NMR spectroscopy.

#### Complex speciation under catalysis conditions

A mixture of 1, 2b or 3 (3  $\mu$ mol, 2 mol%), KO<sup>f</sup>Bu (7.5  $\mu$ mol, 5 mol%), <sup>i</sup>PrOH (0.4 mL) and THF- $d_8$  in an NMR tube was analyzed by NMR spectroscopy after sonication at room temperature for 5 min. After 30 min heating at 80 °C the mixture was again analyzed by NMR spectroscopy. Then benzophenone (0.15 mmol) was added, and the tube was heated at 80 °C for an additional 30 min. After cooling down the reaction mixture was analyzed by NMR spectroscopy (Fig. S13–S21†). The reactions with 1 are complicated and contain many species that change at each step. The major species observed in the reactions with 2b and 3 are assigned to 2b' and 3', respectively. NMR chemical shifts of observed species are provided below.

Relevant NMR signals for **2b**':  $^{1}$ H NMR (THF- $d_{8}$ , 25  $^{\circ}$ C, 400 MHz): -7.54 (bt,  $^{2}J_{PH}$  = 18 Hz, 1H, Ru- $\underline{\text{H}}$ ) ppm.  $^{31}$ P{ $^{1}$ H} NMR (THF- $d_{8}$ , 25  $^{\circ}$ C, 161.9 MHz): 57.7 ppm.

Relevant NMR signals for 3':¹H NMR (THF- $d_8$ , 25 °C, 400 MHz): -7.41 (dt,  ${}^2J_{\rm PH}$  = 85.7 Hz,  ${}^2J_{\rm PH}$  = 19.0 Hz (*cis* PPh<sub>2</sub>),  ${}^1H$ , Ru- $\frac{H}{H}$ ) ppm.  ${}^{31}$ P{¹H} NMR (THF- $d_8$ , 25 °C, 161.9 MHz): 56.0 (d,  ${}^2J_{\rm PP}$  = 18 Hz for Ru-PPh<sub>2</sub>), -27.7 ppm (t,  ${}^2J_{\rm PP}$  = 18 Hz, Ru- $\frac{P}{H}$ Me<sub>3</sub>) ppm.

#### Ligand exchange studies

A mixture of **2a** or **4** (10  $\mu$ mol, 1 equiv.), <sup>i</sup>PrOH (300  $\mu$ mol, 30 equiv.), and PMe<sub>3</sub> (11  $\mu$ mol, 1.1 equiv.) in THF- $d_8$  (0.15 mL) combined in an NMR tube and heated at 80 °C for 30 minutes. After analyzing by NMR spectroscopy, KO<sup>t</sup>Bu (10  $\mu$ mol, 1 equiv.) was added to the reaction mixture and further heated at 80 °C for 30 minutes. After cooling the reaction mixtures were analyzed by NMR spectroscopy (Fig. S83–S88†).

Relevant NMR signals for  $2\mathbf{a} + \mathbf{PMe_3}$ :  $^1\mathbf{H}$  NMR (THF- $d_8$ , 25 °C, 400 MHz): -7.58 (t,  $^2J_{\mathrm{PH}} = 18.1$  Hz, 1H, Ru- $\underline{\mathbf{H}}$  of 2a'), -7.58 (dt,  $^2J_{\mathrm{PH}} = 90$ . Hz,  $^2J_{\mathrm{PH}} = 18.4$  Hz (cis PPh<sub>2</sub>),  $^1\mathbf{H}$ , Ru- $\underline{\mathbf{H}}$ ), -7.60 (t,  $^2J_{\mathrm{PH}} = 19.7$  Hz, 1H, Ru- $\underline{\mathbf{H}}$  of 2a') ppm.  $^{31}\mathbf{P}\{^1\mathbf{H}\}$  NMR (THF- $d_8$ , 25 °C, 161.9 MHz): 62.2 (s, for Ru-PPh<sub>2</sub> of unknown species), 58.7 (s, 2a'), 58.5 (d,  $^2J_{\mathrm{PP}} = 18$  Hz, Ru- $\underline{\mathbf{P}}$ Me<sub>3</sub> of 3'), -27.9 (t,  $^2J_{\mathrm{PP}} = 18$  Hz, Ru- $\underline{\mathbf{P}}$ Me<sub>3</sub> of 3') ppm.

Relevant NMR signals for  $\mathbf{4} + \mathbf{PMe_3}$ . H NMR (THF- $d_8$ , 25 °C, 400 MHz): -7.6 (dt,  ${}^2J_{\mathrm{PH}} = 90.5$  Hz,  ${}^2J_{\mathrm{PH}} = 18.9$  Hz, 1H, Ru-H of 3'), -9.0 (t,  ${}^2J_{\mathrm{PH}} = 18.4$  Hz, 1H, Ru-H of 4'), -13.2 (t,  ${}^2J_{\mathrm{PH}} = 17.9$  Hz, Ru-H of unknown species) ppm.  ${}^{31}\mathbf{P}_{1}^{1}\mathbf{H}$  NMR (THF- $d_8$ , 25 °C, 161.9 MHz): 61.8 (d,  ${}^2J_{\mathrm{PP}} = 8$  Hz, Ru-PPh<sub>2</sub> of unknown species), 60.9 (d,  ${}^2J_{\mathrm{PP}} = 34.2$  Hz, Ru-PPh<sub>2</sub> of unknown species), 58.9 (bs, Ru-PPh<sub>2</sub> of 3' + 4'), -20.5 (s, Ru-PMe<sub>3</sub> of unknown species), -28.0 ppm (bs, Ru-PMe<sub>3</sub> of 3' + unknown species) ppm.

## Results and discussion

#### Syntheses and characterization

As shown in Scheme 1, the  $[(PhPN^HP)Ru(H)(L)(CO)][BPh_4]$  complexes, where L is CyNC (2a),  $^tBuNC$  (2b),  $^nBuNC$  (2c), BnNC (2d),  $PMe_3$  (3), and N-heterocyclic carbene

Paper **Dalton Transactions** 

Scheme 1 Synthesis of 2a, 2b, 2c, 2d, 3 and 4.

2a-d, 3, and 4 were determined by NMR and FTIR spectroscopies, and SCXRD.

The solution NMR spectra of 2a-d, 3, and 4 share a few characteristic signals of the six coordinate Ru-H cations. The <sup>1</sup>H NMR spectra of all the complexes contains a signal for the hydride at -7.3 to -9.0 ppm ( ${}^2J_{HP} = 15-19$  Hz) which is significantly shifted to higher field with respect to neutral 1 (-15.1 ppm) and other neutral analogues containing halide or alkoxide trans ligands<sup>9,26,27</sup> supporting that the ligand exchange and cation formation have significant effect on the electronics of the metal center. The new complexes also exhibit singlets in their <sup>31</sup>P NMR spectra (57–59 ppm) supporting the complexes maintain  $C_s$  symmetry. The Ru-H signal in the <sup>1</sup>H NMR spectrum of 3 is a doublet of triplets with a large doublet coupling constant value of  ${}^{2}J_{HP}$  = 86 Hz which is similar to other Ru-H with a trans PMe3 ligand supports that the PMe<sub>3</sub> ligand is trans to the hydride and not cis. 25-27 Catalysts 2a-d, 3, and 4 were further studied by the FTIR spectroscopy to obtain electronic structure information.

The FTIR spectra of 2a-d contain signals for the isonitrile  $(\nu_{\rm CN} = 2160 - 2178 \text{ cm}^{-1})$  ligands with stretching frequencies that are similar to the bis-isonitrile cations reported by Gauvin and coworkers (cis  $\nu_{\rm CN} = 2059 \ {\rm cm}^{-1}$ , trans  $\nu_{\rm CN} = 2135 \ {\rm cm}^{-1}$ ), <sup>24</sup> supporting that these complexes are cations and the isonitrile ligands are trans to the hydride. The FTIR spectra of all 6 new complexes in this study contain a signal for the trans carbonyl ( $\nu_{\rm CO}$  = 1931–1961 cm<sup>-1</sup>), which lie at frequencies similar to the cis CO of the bis-carbonyl cation reported by Prakash and coworkers (cis  $\nu_{CO} = 1964 \text{ cm}^{-1}$ , trans  $\nu_{CO} = 2052 \text{ cm}^{-1}$ ).<sup>28</sup> In general, the complexes, 3 and 4, containing strong  $\sigma$ -donating ligands exhibit lower FTIR  $\nu_{\rm CO}$  stretch frequencies due to the increased electron density as expected. The solid-state structures of 2b, 2d, 3 and 4 were further confirmed by SCXRD analyses (see ESI† for details).

The SCXRD structures (Fig. 2) indicate that the N-H is anti to the Ru-H in the solid state. The structure of the cation in the SCXRD structure of 3 is similar to the same previously published cation with alkoxide anions.25 1H-1H NOESY NMR experiments could not identify significant N-H and Ru-H correlations in any of the catalysts in this study supporting that the anti-isomer is the major species in solution as well. After analyzing the structures, we compared the catalytic activity of 2a-2d, 3, and 4 to 1 for ketone transfer hydrogenation reaction.

Fig. 2 SCXRD of 2b (A), 2d (B), 3 (C), and 4 (D), thermal ellipsoids are drawn at 50% probability. The BPh4 anions, solvent molecules and most hydrogen atoms are omitted for clarity. See ESI† for further details.

#### Catalysis studies

1 and other Ru pincer complexes are well known to perform carbonyl reduction reactions, therefore we elected to benchmark the new complexes in this work in the transfer hydrogenation of ketones with isopropanol. To identify mechanistically viable reaction conditions, the reduction of benzophenone was performed with isopropanol and KO<sup>t</sup>Bu as the base with 2a as the catalyst (Table S1†). Catalyst loadings of 0.1 mol% of catalyst and 0.625 mol% of base in neat isopropanol were chosen to compare the different catalysts in this study with 1 (Table 1).

The alkyl isonitrile catalysts, 2a-2c, exhibited comparable catalytic activities to 1. The alkyl isonitriles were originally chosen to determine if the steric environment of the trans ligand effects the reactivity of the catalyst. However, no distinguishable trend was observed, indicating the structure of the ligand had little effect on the overall structure. On the other hand, 2d is a much slower catalyst than 1, showing that the electron withdrawing ligand reduces the catalysts activity for this reaction, supporting that the electronic environment of the ligand trans to the Ru-H has a strong effect on the catalytic activity. On the contrary, 3 and 4 are more active than 1 and 2a-2d, supporting that  $\sigma$ -donating ligands enhance the catalyst activities. We hypothesize that the  $\sigma$ -donating ligands enhance the nucleophilicity of the Ru-H, speeding up the initial reaction with the substrate. To better understand the effects of the trans ancillary ligand on catalyst activity, selectivity, and stability we tested the transfer hydrogenation of functionalized acetophenones.

Functional group tolerance is a common challenge in catalysis; therefore, we examined the new catalysts abilities to

reduce acetophenones under similar conditions to compare their functional group tolerances to 1. 1, 2a, 3, and 4 were tested for the transfer hydrogenation of 4-bromoacetophenene, acetophenone, and 4-methoxyacetophenone with isopropanol (Table 2). For acetophenone, all four catalysts completed the reaction within 1-2 hours, with the electron rich 3 and 4 completing the reactions faster in general. Interestingly, 3 and 4 were notably more chemoselective than 1 (96 vs. 84%). The enhanced chemoselectivity differences are more pronounced for bromoacetophenone where 3 and 4 produce 4-bromo- $\alpha$ -methylbenzyl alcohol with selectivities of  $\sim$ 90%, whereas 1 and 2a only generated the product with 62 and 72% selectivities, respectively. In the reduction of methoxyacetophenone, all 4 catalysts stopped consuming the ketone at ~75-84% conversion, suggesting the reactions reach an equilibrium. The selectivities for 4-methoxy-α-methylbenzyl alcohol were again low for 1 and high for 3 and 4 (65 vs. 99%). In general, the cation precursors were more chemoselective for the expected alcohol products. This may be attributed to the known instability of active intermediates of 1 in similar reactions. 25,29 The addition of a ligand trans to the Ru-H has been previously shown to improve the stability of 1, forming neutral (PhPNP) Ru(H)(CO)(PR<sub>3</sub>) and cationic [(PhPN<sup>H</sup>P)Ru(H)(CO)(PR<sub>3</sub>)]<sup>+</sup> complexes that are highly active alcohol dehydrogenation and ester

#### Attempts to determine catalyst speciation

hydrogenation catalysts.

**Dalton Transactions** 

We hypothesized that the newly introduced ancillary ligands trans to the hydride remain bound to Ru during catalysis. However, the possibility remains that the improved activity and selectivities are the result of ligand stabilization of active species and requires the dissociation of the ligand to form the active species. The requirement of base in the catalysis also suggests that the active species may be a neutral species, such as (PhPNP)Ru(H)(CO) which was proposed by Schaub and coworkers by dissociation of PMe3 from (PhPNP)Ru(H)(PMe3) (CO).25 Also, the active species in these types of reactions is generally believed to contain an NH syn to the hydride, which contributes to the complexes ability to perform metal-ligand cooperative reactions.<sup>30</sup> However, the complexes in this work contain anti motifs. Therefore, we performed a number of high catalyst loading and other reactions in an effort to determine the catalyst resting state and active speciation.

In isopropanol, 1 reacts with KO<sup>t</sup>Bu (2.5 equiv.) to form multiple species based on NMR spectroscopy (see Fig. S13–S15†). (PhPN<sup>H</sup>P)Ru(H)<sub>2</sub>(CO)<sup>18</sup> forms in the initial reaction along with several unidentifiable species. After heating and addition of benzophenone the speciation changes at every step, consistent with previous reports. On the other hand, dissolution of 2b or 3 in isopropanol followed by the addition of KO<sup>t</sup>Bu (2.5 equiv.) results in only minor shifting of the <sup>1</sup>H and <sup>31</sup>P NMR chemical shifts (assigned 2b' and 3', respectively, see Fig. S16–S21†). There is no indication of the formation of neutral (PhPNP)Ru(H)(L)(CO) species or other major species with significantly different structures, showing the stability of the cations. For example, the major species in the reactions

with 3 contains <sup>31</sup>P NMR chemical shifts of 56.0 and -27.7 ppm, which are very similar to 3 (<sup>31</sup>P NMR chemical shifts = 56.5 & -26.8 ppm in THF- $d_8$ ) and differ from (PhPNP) Ru(H)(PMe<sub>3</sub>)(CO) (<sup>31</sup>P NMR chemical shifts = 67.1 and -25.2 ppm in THF- $d_8$ ).<sup>25</sup> Also, the hydride signal in the <sup>1</sup>H NMR of 3' has a chemical shift of -7.41 (*trans*  $^2J_{PH}$  = 85.6 Hz) that is nearly identical to the hydride signal of 3 (-7.38 ppm, *trans*  $^2J_{PH}$  = 85.6 Hz) and differs from (PhPNP)Ru(H)(PMe<sub>3</sub>) (CO) (-8.02 ppm,  $^2J_{PH}$  = 104.8 Hz).

This data suggests that the [(PhPN<sup>H</sup>P)Ru(H)(L)(CO)]<sup>+</sup> ions are persistent in the presence of isopropanol. The small changes in chemical shift may be due to changing the solvent mixture or inversion of the NH from *anti* to *syn*, relative to the hydride (Scheme 2). Studies have shown that proton shuttling in pincer complexes is accelerated in alcoholic solvents, so it would not be surprising if inversion of the NH *via* deprotonation followed by re-protonation is facile in isopropanol.<sup>31</sup> The analogous [(PhPN<sup>H</sup>P)Ru(H)(PMe<sub>3</sub>)(CO)][OR]<sup>25</sup> complexes ([OR] = [OPh] and [OMe]) have similar NMR chemical shifts and coupling constants to 3 and 3′, therefore anion exchange of the [BPh<sub>4</sub>]<sup>-</sup> ion for an [O<sup>i</sup>Pr]<sup>-</sup> ion in 3′ cannot be ruled out. Also, transient neutral species may yet form as the active species and not be observable under catalytic conditions by NMR spectroscopy.

Schaub and coworkers observed hydrogenation and dehydrogenative coupling catalysis with the (PhPNP)Ru(H)(CO) (PR<sub>3</sub>) complexes in the presence of excess PPh<sub>3</sub> (3-13 equivalents) with only slight reductions in catalysis rates with in situ combinations and isolated pre-catalysts. A summary of similar transfer hydrogenation catalysis attempts for transfer hydrogenation of benzophenone with 1, 2a, and 3 is provided in Table 3. In contrast to the hydrogenation and dehydrogenative coupling reactions, addition of PMe<sub>3</sub> (1.4 equiv.) to 1 under the same transfer hydrogenation conditions in Table 1, entry 1 resulted in a significant reduction in catalysis (Table 3, entry 1). Similarly, in situ combinations of 1, PMe<sub>3</sub> (1 equiv.), and NaBPh4 (1 equiv.) resulted in no observed catalysis. These observations may be due to comparatively slow reactions of PMe<sub>3</sub>, and NaBPh<sub>4</sub> with 1 under catalytic conditions due to low concentrations and competitive side reactions, such as [(PhPN<sup>H</sup>P)Ru(H)(CO)]<sub>2</sub>[BPh<sub>4</sub>]<sub>2</sub> dimer formation or other unknown reactions. Addition of 1 or 5 equivalents of PMe3 to 3 under catalytic conditions resulted in mere 25% and 0% yields of diphenylmethanol, respectively. The same loss in activity was observed with 2a in the presence of excess CyNC. NMR spectroscopy of Table 3, entry 5 shows no change in the catalyst speciation in the presence of excess PMe<sub>3</sub> (Fig. S10-S12†).

Scheme 2 Proposed reactions of 2b and 3 with KO<sup>t</sup>Bu in <sup>i</sup>PrOH.

**Paper** 

This suggests that the ligand may need to dissociate to form

the active catalysts and transfer hydrogenation is more sensitive to the presence of excess ligand than hydrogenation and dehydrogenative coupling catalyses.

To confirm the ligands trans to the hydride are labile, we attempted to exchange the ligands in 2b and 4 with PMe<sub>3</sub> (1.1 equiv.). No exchange was observed in the presence of isopropanol (30 equiv.) (Fig. S83-S88†). However, upon introduction of base, some exchange and 3' was observed with heating at 80 °C. This suggests that the ligands trans to the hydride may dissociate when exposed to catalytic conditions, however more studies will be required to determine if this observation is relevant to the transfer hydrogenation of ketones and other catalytic reactions.

At high catalyst loadings (2 mol% Ru) of 2b or 3 the NMR signals of the catalysts are similar to the starting complexes in THF-d<sub>8</sub> indicating minimal changes to the chemical structures of the [(PhPN<sup>H</sup>P)Ru(H)(CO)(L)]<sup>+</sup> ions. The observed species are likely off-cycle, catalyst resting states. The addition of extra ligand during catalysis suggests that the mechanism may require dissociation of the ligand trans to the hydride to form the active species and the improved chemoselectivities of these complexes is due to stabilization of the active speces by the labile ligand. However, the significant activity increases of 3 and 4 over 1 suggest the mechanism may be more complicated or the active species is the [(PhPNHP)Ru(H)(CO)]+ ion under these conditions. More studies, including computations, will be necessary to definitively determine the speciation of [(PhPNHP)Ru(H)(CO)(L)][BPh4] in transfer hydrogenation catalysis conditions.

## Conclusions

In this work, a series of cationic Ru pincer complexes were synthesized via ligand substitution of the chloride in Ru-MACHO followed by anion exchange to study the effects of the ancillary ligand trans to the Ru-H bond. NMR spectroscopy and SCXRD revealed that all 6 new catalysts contained an N-H that was anti to the Ru-H and the new ancillary ligand was trans to the Ru-H allowing for direct comparisons. The complexes catalyze the transfer hydrogenation of ketones utilizing isopropanol as the hydrogen source. In general, electron poor,  $\pi$ -accepting ligands resulted in slower catalysis, whereas sigma donors accelerated the catalysis compared to Ru-Macho. The additional ligands improved the chemoselectivity of the transfer hydrogenation of acetophenones, especially for functionalized acetophenones. These studies contribute to the continuing understanding of pincer complex reactivity and design principles for building more active and stable catalysts.

## Author contributions

All authors contributed to the project design. M.H., D.C.C., and A.M.C. performed the laboratory syntheses, catalysis, and spectroscopic characterizations. The manuscript was written through contributions by all authors. All authors have given approval to the final version of the manuscript.

## Data availability

Crystallographic data for the structures reported in this article have been deposited at the Cambridge Crystallographic Data Centre under deposition numbers 2392950-2392953.† NMR spectra and other data are provided in the ESI† associated with this publication.
