Simulant chemistry for uranium and plutonium molten fuel salts: crystallographic investigation and thermodynamic modelling assessment of the NaCl–RECl₃ and NaCl–MgCl₂–RECl₃ (RE = Ce, Nd) systems

Dennis C. Alders,^a Ana Sacristán-Civera,^a Mädchen Wolff,^a Elisa Capelli,^d Eleanor L. Bright,^{b,c} Christoph Hennig,^{b,c} Rudy J. M. Konings^a and A. L. Smith^{*,a}

In this study, new insights into the solid state chemistry of the systems NaCl–RECl₃ (RE = Ce, Nd) are presented, in which the intermediate compound suggested in the literature, *i.e.* Na₃RE₅Cl₁₈, is investigated more closely. Our studies have revealed a solubility range around the intermediate composition in the form of the Na_{3/2}RE_{1–2/3}Cl₃ stoichiometry, and have allowed us to revisit the phase diagrams of the NaCl–RECl₃ (RE = Ce, Nd) systems accordingly. Furthermore, we demonstrate that among the lanthanide chlorides, NdCl₃ is the prime simulant candidate for the melting behaviour of PuCl₃-based systems, while CeCl₃ is most suited to simulate UCl₃-based systems. This is corroborated in this work by comparing the melting profiles of the NaCl–MCl₃, MgCl₂–MCl₃, and NaCl–MgCl₂–MCl₃ (M = Ce, Nd, U, Pu) systems. In doing so, the binary systems MgCl₂–MCl₃ (M = Ce, Nd) have been re-visited based on existing data in the literature and estimated mixing enthalpies. Extrapolations to the ternary systems NaCl–MgCl₂–RECl₃ (RE = Ce, Nd) have been made and compared to the available data in the literature, showing good agreement.

1 Introduction

Molten chloride salts are a class of materials that are central in the development of fast neutron spectrum Molten Salt Reactor (MSR) development. In this type of nuclear reactor, chloride salts can be used as both fuel and coolant. The reason for this lies in their attractive qualities, notably their high thermochemical stability and low vapour pressures, even at elevated temperatures, and their high actinide solubility.^{1,2} For a safety assessment of the MSR, a thorough understanding of the thermodynamic and thermo-physical properties of the fuel salts is needed. Salt systems that have garnered interest as candidate fuels are the systems NaCl–PuCl₃,³ NaCl–UCl₃,⁴ and NaCl–MgCl₂–PuCl₃,^{5–7} with this work focussing mainly on the latter fuel system. Since there is a dearth of available experi-

mental data on the systems with PuCl₃ in general, additional data are urgently needed to assist the safety assessment of the molten chloride reactor. At this stage of MSR development, the amounts of PuCl₃ available for research are limited as it needs to be produced in special facilities due to its hazardous nature. Therefore, using an approach that does not involve the use of PuCl₃ may be desirable to reduce the number of necessary experiments. In particular, a close inspection of the (conflicting) available data in simulant systems with lanthanide elements is meaningful. In this work, we have scrutinized systems with lanthanide chlorides from La to Yb (and Y) to identify the elements whose behaviour is closest to that of the actinides in molten chloride salts, and to identify the most suitable simulant for the melting behaviour of PuCl₃-based systems. We have found that NdCl₃ and CeCl₃ are the closest surrogates for NaCl–AnCl₃, MgCl₂–AnCl₃ and NaCl–MgCl₂–AnCl₃ (An = U, Pu) systems, thereby calling for a close inspection of the corresponding rare earth chloride systems.

Experimental investigations using X-ray diffraction (XRD) have been performed to fill in important gaps that became evident after analyzing the data in the literature, *i.e.* related to the solid-state chemistry in the NaCl–RECl₃ systems. There is no single interpretation of the stable intermediate compounds in these systems, with some authors claiming a stoichiometry

of $\text{NaRE}_3\text{Cl}_{10}$,^{8,9} $\text{Na}_3\text{RE}_5\text{Cl}_{18}$ ^{10,11} or $\text{Na}_{2x}(\text{Na}_x\text{RE}_{2-x})\text{C}_{16}$,^{12,13} with the latter indicating possible solid solubility. Subsequently, CALPHAD models of the binary sub-systems NaCl-NdCl_3 and NaCl-CeCl_3 have been developed. The thermodynamic models use the quasi-chemical formalism in the quadruplet approximation for the liquid solutions, and a one-lattice polynomial model for the solid solutions. Moreover, the systems $\text{MgCl}_2\text{-MCl}_3$ ($M = \text{Ce, Nd, U, Pu}$) were modelled based on the available phase diagram data in the literature, and estimated mixing enthalpy data using the method of Davis and Rice,¹⁴ as described in more detail in a previous work.¹⁵ This allowed us to consider more generally the similarities in the $\text{NaCl-MgCl}_2\text{-MCl}_3$ ($M = \text{Ce, Nd, U, Pu}$) systems.

2 Methods

2.1 Experimental techniques

2.1.1 Sample preparation. For the experiments carried out in this work, the end-members NaCl , NdCl_3 and CeCl_3 were used in their respective ultra-dry forms, as delivered by the supplier. The purity has been verified by X-Ray diffraction (XRD) and Differential Scanning Calorimetry (DSC), as shown in Table 1. No secondary impurity phases were detected, and the measured melting temperatures were found in excellent agreement with the data in the literature. Due to the sensitivity of the salts towards oxygen and water, all sample preparation was carried out inside a glove box under dry argon atmosphere (H_2O , $\text{O}_2 < 5$ ppm).

Weighing was carried out using a Mettler-Toledo XPE105DR balance with a 0.01 mg uncertainty. Sample preparation was conducted by mixing end-members in the appropriate stoichiometric ratios in an agate mortar inside the dry argon atmosphere in the glovebox. The sample containers were either nickel liners in stainless steel crucibles, also used in our previous works,^{15,18,19} or vacuum-sealed borosilicate ampoules. Subsequently, the mixtures were subjected to a heat treatment for 48 h at $T = 693$ K, either in a tubular furnace under argon flow or in a chamber furnace under air.

2.1.2 Quenching experiments. The high-temperature stability of the intermediate compound in the NaCl-CeCl_3 and NaCl-NdCl_3 systems was investigated in this work using quenching experiments. The quenching samples consisted of stoichiometric mixtures of the end-members, thoroughly mixed using a pestle and mortar before insertion inside a nickel liner in a tightly closed stainless steel crucible. During the experiments, the samples were heated to a temperature of 773 K and equilibrated at this temperature for at least two

hours, after which they were dropped into a water bath to freeze the phases stable at high temperature. No difference in obtained XRD pattern was observed when quenching after 4 hours of heat treatment instead of 2.

The furnace used for quenching was an MTI split vertical quenching tube furnace (OTF-1500X-80-VTQ), which contained an electromagnet that held the sample in the heated part of the furnace. When the sample was at the desired temperature and had reached equilibrium, the electromagnet was shut off and the sample dropped into a water bath. Due to the double containment of the sample of nickel inside stainless steel, the sample stayed water-free during this experiment.

2.1.3 X-ray diffraction (XRD)

Laboratory XRD. XRD measurements were carried out using a PANalytical X'pert pro diffractometer with a Cu-anode (0.4 mm \times 12 mm line focus, 45 kV, 40 mA). Scattered X-ray intensities were measured with a real-time multi-step detector (X'Celerator). The angle 2θ was set to cover a range from 10° to 120° . Measurements were typically performed for 7–8 hours, with a step size of $0.0036^\circ \text{ s}^{-1}$. Refinement of the measured XRD data was performed by applying the method of Rietveld, Loopstra and van Laar,^{20,21} using the FullProf software, Version 5.10.²² Visualisation of the crystal structure based on the refined XRD data was done with the VESTA software.²³

Synchrotron XRD. In addition to XRD measurements obtained in our lab, high resolution synchrotron XRD (sXRD) measurements were performed. The resolution of synchrotron diffraction, $\delta d/d$, is $1\text{--}2 \times 10^{-3}$ (depending on the capillary diameter, scattering angle and excitation energy), and thus typically a magnitude better than that of the lab diffractometer. It was used to investigate small impurities or additional phases that would otherwise be invisible on an XRD. The sXRD measurements were performed at the XRD-1 station of the ROBL beamline (BM20) at the ESRF.²⁴ This station was equipped with a 6-circle diffractometer and a Eiger CdTe 500k detector (Dectris). The wavelength of the synchrotron radiation was $\lambda = 0.76533 \text{ \AA}$, and the beam size was $300 \times 300 \mu\text{m}$. The sample was enclosed in a $300 \mu\text{m}$ diameter glass capillary sealed with epoxy glue itself enclosed inside a Kapton tube. Data were collected in transmission mode at 296 K and reduced using the PyFAI software suite.²⁵ Data were collected from $0 \leq 2\theta \leq 66^\circ$. Refinement of the measured XRD data was also performed by applying the method of Rietveld, Loopstra and van Laar,^{20,21} using the FullProf software, Version 5.10.²²

2.2 Thermodynamic modelling

The thermodynamic modelling assessment of the molten salt systems was performed with the CALPHAD method²⁶ using the

Table 1 Pure compounds used in the experiments in this work

Compound	Supplier	CAS No	Reported purity	Melting point (DSC, K)	Melting point (lit., K)
NaCl	Merck	7647-14-5	99.998%	1074 ± 5	1074 ± 1^{16}
NdCl_3	Thermo-Fischer	10024-93-8	99.99%	1031 ± 5	1030 ± 2^{17}
CeCl_3	Alfa Aesar	7790-86-5	99.9%	1087 ± 5	1090 ± 2^{17}

FactSage software, Version 8.2.²⁷ Both literature and experimental data obtained in this work were used to optimize the excess parameters of the Gibbs energy functions of the phases present in the systems.

2.2.1 Stoichiometric compounds. The Gibbs energy function for stoichiometric compounds is dependent on the standard enthalpy of formation ($\Delta_f H_m^\circ(298)$), the standard entropy ($S_m^\circ(298)$) at the reference temperature of 298.15 K and the heat capacity ($C_{p,m}^\circ(T)$) as shown in eqn (1) (with T in K).

$$G(T) = \Delta_f H_m^\circ(298) - S_m^\circ(298)T + \int_{298}^T C_{p,m}^\circ(T) dT - T \int_{298}^T \frac{C_{p,m}^\circ(T)}{T} dT \quad (1)$$

The isobaric heat capacity $C_{p,m}$ is expressed as a polynomial that takes the form of eqn (2).

$$C_{p,m}(T) = a + bT + cT^{-2} + dT^2 + eT^{1/2} \quad (2)$$

The thermodynamic data for all compounds are listed in Table 2. To be consistent with previous works^{15,18,19,28–30} and the JRC Molten Salt Database,³¹ thermodynamic data for $MgCl_2$ were taken from the JANAF thermochemical database,¹⁶ the thermodynamic data for $NaCl$ was taken from van Oudenaren *et al.*,³² and the thermodynamic data for $CeCl_3$ and $NdCl_3$ were taken from the review by Konings and Kovács.¹⁷ The thermodynamic data for $PuCl_3$ and UCl_3 were taken from the review by Capelli and Konings,³³ with the heat capacity of UCl_3 taken from the re-assessment by van Oudenaren *et al.*³² The thermodynamic model of the $NaCl$ – $MgCl_2$ system was presented in a previous work¹⁸ and is used in this work as such.

2.2.2 Liquid solution. The excess Gibbs energy terms of the liquid solution are modelled using the quasi-chemical formalism in the quadruplet approximation as proposed by Pelton *et al.*³⁶ which has proven to be well-adapted to molten chloride and fluoride systems. This description assumes the existence of cation–anion quadruplets in the liquid, *i.e.* in the form of $A-X-B-Y$ ($A, B =$ cations; $X, Y =$ anions), allowing for the modelling of short-range ordering. This formalism allows for the selection of the composition of maximum short-range ordering through its coordination numbers, corresponding to the minimum of the Gibbs energy that is often found near the composition of the lowest eutectic. By fixing either the cation–cation or anion–anion coordination number, the opposite coordination number is also obtained through eqn (3), where q_i are the charges of the respective ions. In this work, we can simplify the description to the $A-X-B-X$ quadruplet as chlorine is the only anion we consider. The coordination numbers used in the thermodynamic model presented in this work are given in Table 3.

$$\frac{q_A}{Z_{AB/XX}^A} + \frac{q_B}{Z_{AB/XX}^B} = 2 \frac{q_X}{Z_{AB/XX}^X} \quad (3)$$

The excess parameters that are optimized are those related to the second-nearest neighbour exchange reactions as given in eqn (4). The associated change in Gibbs energy of eqn (4) is expressed in eqn (5).

Table 2 Thermodynamic functions used in the CALPHAD model in this work. Optimized values are marked in bold. Note that compounds marked with an asterisk are not stoichiometric intermediates, but rather end-members of the $Na_{3x}RE_{2-x}Cl_6$ solid solution as specified in section 2.2.3

$$\Delta g_{AB/XX} = \Delta g_{AB/XX}^{\circ} + \sum_{i \geq 1} g_{AB/XX}^{i\circ} \chi_{AB/XX}^i + \sum_{j \geq 1} g_{AB/XX}^{j\circ} \chi_{BA/XX}^j \quad (5)$$

In eqn (5) the terms $\Delta g_{AB/XX}^{\circ}$, $\Delta g_{AB/XX}^{i\circ}$ and $\Delta g_{AB/XX}^{j\circ}$ are composition-independent coefficients that may depend on temperature. The composition dependence of the Gibbs energy is apparent through $\chi_{AB/XX}$ as these are defined as per eqn (6). In this equation X_{AA} is the cation-cation pair fraction, or the molar fraction of the quadruplet containing two cations A. For this binary system, $\{X_{AA} + X_{AB} + X_{BB}\}$ is equal to one.

$$\chi_{AB/XX} = \frac{X_{AA}}{X_{AA} + X_{AB} + X_{BB}} \quad (6)$$

The Gibbs energy functions used in this work to describe the liquid solutions are given in Table 4. Using the data for the binary systems as a basis, extrapolations to the ternary and quaternary fields were made with Kohler/Toop interpolations, due to the asymmetry of the system. In this work, MgCl_2 , CeCl_3 and NdCl_3 are considered asymmetric components, as their ionic structure in the liquid (*i.e.* molecular species) is different from the sodium halides (*i.e.* ionic species). No ternary optimization terms were added, to be consistent with the work of Beneš *et al.*³⁷

2.2.3 Solid solution modelling of $\text{Na}_{3x}\text{RE}_{2-x}\text{Cl}_6$. The thermodynamic description of solid-solutions is done using the one-lattice polynomial model to be consistent with the

Table 5 Optimized excess Gibbs energy functions used in the CALPHAD model in this work for the solid solution

A	B	L_{AB}^{11}
NaCl	NaCe_2Cl_7	$-9000 + 15 \text{ T}$
NaCl	NaNd_2Cl_7	$-6500 + 7.5 \text{ T}$

description of the JRC Molten Salt Database (JRCMSD).³¹ The Gibbs Energy function of the solid-solution is given in eqn (7).

$$G(T) = X_A \cdot G_A^{\circ} + X_B \cdot G_B^{\circ} + X_A RT \ln X_A + X_B RT \ln X_B + \Delta G_m^{\text{excess}} \quad (7)$$

In the above equation, G_i° are the end-member molar Gibbs energies, and X_i are the site molar fractions of the end-members A and B, respectively. The third and fourth terms in eqn (7) represent the configurational entropy. The excess Gibbs energy, present in eqn (7) as $\Delta G_m^{\text{excess}}$, is defined as per eqn (8).

$$\Delta G_m^{\text{excess}} = \sum_{ij \geq 1} X_A^i X_B^j L_{AB}^{ij} \quad (8)$$

The term L_{AB}^{ij} in eqn (8) is an interaction coefficient that can be a function of temperature if necessary. The terms X_A^i and X_B^j are the site molar fractions of end-members A and B. To model the homogeneity range of the $\text{Na}_{3x}\text{RE}_{2-x}\text{Cl}_6$ intermediate, the NaCl and NaRE_2Cl_7 end-members were selected in this work. It is important to note that the Gibbs energy of the NaCl end-member was also destabilised with an arbitrary enthalpic term of $+5000 \text{ J mol}^{-1}$ to be able to reproduce accurately the phase diagram data. The corresponding Gibbs energy functions are given in Table 5.

3 Results and discussion

3.1 Simulant selection

Cerium has often been cited as actinide surrogate in the literature,^{38–41} but other rare earth elements show comparable behaviour. Cerium is commonly used for the fact that its stable oxidation states (*i.e.* +3 and +4) mirror that of plutonium

^a Re-optimized from the work of Yingling *et al.*³⁵ to reproduce the same phase diagram with a different choice of end-member function for UCl_3

in oxide systems, where CeO_2 and Ce_2O_3 can be used as simulant for PuO_2 and Pu_2O_3 , respectively. In a molten salt environment, Pu is mostly stable in its +3 oxidation state (*i.e.* PuCl_3), but can oxidize to +4 in case oxychlorides or oxides form (*i.e.* PuOCl_2 ,^{42,43} PuO_2 ⁴⁴). Only a few lanthanides are stable in the +4 oxidation state, among which Ce, which is why Ce seems like the most logical choice at first glance. However, when looking at the melting behaviour and ionic radius, it may not be the most suitable lanthanide to fill the role of simulant element, as we show in this work. This observation is in agreement with the work of Goloviznina *et al.*,⁴⁵ who show based on DFT calculations and MD simulations that NdCl_3 is the most appropriate simulant for PuCl_3 with respect to density and viscosity in molten NaCl-MCl_3 ($M = \text{Nd, Ce, Pu}$) chlorides.

A comparison of the melting behaviour of different lanthanide chloride-alkali chloride systems has been made by collecting experimental liquidus data reported in the literature for the systems NaCl-MCl_3 .^{8–10,35,40,46–60} The decision on which potential simulants to consider is based on the data shown in Fig. 1, which allows for a pre-selection based on similarity with Pu and U at first glance. Shown in these figures is the melting behaviour of NaCl-MCl_3 ($M = \text{La-Yb, Pu, U}$) mixtures as a function of $x(\text{MCl}_3)$, *i.e.* the molar fraction of the MCl_3 species. The systems with NaCl were selected because NaCl is part of the base fuel salt, and there is an abundance of data in the literature.

As seen in Fig. 1b, the liquidus line of the NaCl-NdCl_3 system is almost perfectly overlapping with that of the NaCl-PuCl_3 system. Following the conclusion of Goloviznina *et al.*⁴⁵ that NdCl_3 is the prime candidate for simulating the density and viscosity of PuCl_3 in NaCl-MCl_3 molten chlorides, this work shows that it is also the best simulant with respect to the melting behaviour. Also shown in this figure is the liquidus line of the NaCl-CeCl_3 system, which has been cited as simulant for Pu and U in the literature,^{38–41} but bears the closest resemblance to the liquidus in the NaCl-UCl_3 system. From

this first analysis, we focused our efforts on the chemistry of the NaCl-RECl_3 and $\text{NaCl-MgCl}_2\text{-RECl}_3$ ($\text{RE} = \text{Ce, Nd}$) systems as most suitable surrogates for the corresponding AnCl_3 ($\text{An} = \text{U, Pu}$) systems. A number of open issues were identified for those systems, which we have explored in detail as described hereafter.

3.2 Insights into NaCl-RECl_3 ($\text{RE} = \text{Ce, Nd}$) chemistry

3.2.1 NaCl-NdCl_3 . Experimental data have been reported in the literature on the NaCl-NdCl_3 system by Seifert *et al.* in 1988,⁶¹ who performed Differential Thermal Analysis (DTA) and XRD analyses. They found by XRD that an intermediate compound exists, which they assigned to $\text{Na}_3\text{Nd}_5\text{Cl}_{18}$, also written as $\text{Na}_{0.67}(\text{Na}_{0.33}\text{Nd}_{1.67})\text{Cl}_6$ (space group $P6_3/m$ ⁶¹). Sato *et al.*¹⁰ also presented an experimental investigation of this system in 1998 using DTA and XRD, and they retained the intermediate compound found by Seifert *et al.*, $\text{Na}_3\text{Nd}_5\text{Cl}_{18}$ in their assessment. They suggested that a homogeneity range exists at elevated temperatures, specifically between $x(\text{NdCl}_3) = 0.59$ and $x(\text{NdCl}_3) = 0.70$ and $T = (573\text{--}873)$ K. According to the sketched phase diagram Sato *et al.* reported, the homogeneity range is only stable at elevated temperatures, while the room temperature composition remains $\text{Na}_3\text{Nd}_5\text{Cl}_{18}$. However, neither Sato *et al.* nor Seifert *et al.* reported detailed crystallographic information on the intermediate compound, notably the atomic positions in the crystal structure. Earlier DTA assessments by Igarashi *et al.* (1990)⁹ and Sharma *et al.* (1992)⁸ agreed about the existence of an intermediate, but suggested the intermediate $\text{NaNd}_3\text{Cl}_{10}$ instead, and indicated no homogeneity range. In view of the discrepancies between the literature studies, new investigations of the crystal structures of this compound were performed in this work to address the remaining questions.

In addition to the phase diagram studies found in the literature, single-crystal studies of the intermediate compound by Lissner *et al.* (1994)¹² dived more in detail into the crystal

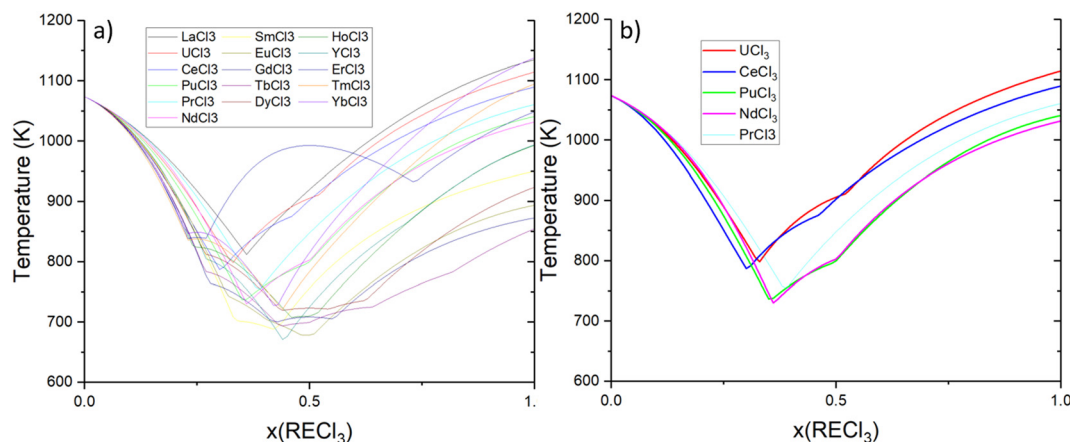

Fig. 1 Liquidus lines of NaCl-MCl_3 systems ($M = \text{La-Yb, Y, U, Pu}$) reported in the literature^{8–10,35,40,46–60} (a), and selected liquidus lines for potential simulant systems (b).

structure chemistry. They reported a structure of $\text{Na}_{0.698}(\text{Na}_{0.35}\text{Ce}_{1.65})\text{Cl}_6$, corresponding to a general stoichiometry of $\text{Na}_x(\text{Na}_{\frac{x}{2}}\text{Nd}_{1-\frac{x}{2}})\text{Cl}_3$ (space group $P6_3/m$). The existence of this compound is confirmed in our work with new experimental investigations, and the description of Lissner *et al.* is thus retained. Moreover, the extent of the homogeneity range is scrutinized in detail for the first time. While the $\text{Na}_x(\text{Na}_{\frac{x}{2}}\text{Nd}_{1-\frac{x}{2}})\text{Cl}_3$ notation gives an insight into the crystallography (e.g. the shared Na/Nd position), in this work we will use the simpler notation $\text{Na}_{3x}\text{Nd}_{2-x}\text{Cl}_6$ or $\text{Na}_{2x}(\text{Na}_x\text{Nd}_{2-x})\text{Cl}_6$. Based on the atomic positions Lissner *et al.* reported for a sample of stoichiometry $\text{Na}_{0.608}(\text{Na}_{0.304}\text{Nd}_{1.696})\text{Cl}_6$, we can define a general description for the $\text{Na}_{3x}\text{Nd}_{2-x}\text{Cl}_6$ phase that has been used in this work (see Table 7, Fig. 2).

Several samples were prepared in this work with varying (NaCl : NdCl_3) ratios as detailed in Section 2.1.1, with the aim of confirming the crystal structure model, and defining the limits of the homogeneity range. Mixtures were prepared within the expected homogeneity range, as well as in the two-phase domains. The mixtures were subjected to thermal treatment at $T = 693$ K for at least 48 hours. A few quenching experiments were also performed at compositions $x(\text{NdCl}_3) = 0.60, 0.625$ and 0.65 at $T = 773$ K. The aim of these experiments was to investigate the behaviour of this compound both at elevated temperatures and at room temperature, following the hints in the literature by Sato *et al.*¹⁰ and Lissner *et al.*¹²

Shown in Fig. 4 is the profile refinement of the composition $x(\text{NdCl}_3) = 0.65$, collected at room temperature using sXRD. This refinement shows that a single phase exists at this composition, with no detectable amounts of the end members NaCl and NdCl_3 . The same was observed for the compositions $x(\text{NdCl}_3) = 0.55, 0.6$ and 0.625 in the same binary system, confirming the existence of an intermediate with a considerable homogeneity range. The $\text{Na}_{3x}\text{Nd}_{2-x}\text{Cl}_6$ phase adopts the same crystal structure symmetry as NdCl_3 (also hexagonal, in space group $P6_3/m$ ¹³). Upon addition of sodium to the NdCl_3 structure, partial substitution of sodium on the Nd site ($2c$) occurs, while the rest of the sodium is located on the $(0,0,0)$ position ($2b$) with an occupancy

Fig. 3 Crystal structure of NdCl_3 as reported by Meyer *et al.*¹³ viewed along the c -axis, with the elements Nd and Cl indicated in orange and green respectively.

equal to x . The shared Nd/Na2 site is nine-fold coordinated (same as in the NdCl_3), while the Na1 site is six-fold coordinated. The crystal structures of $\text{Na}_{3x}\text{Nd}_{2-x}\text{Cl}_6$ and NdCl_3 are shown in Fig. 2 and 3, respectively to illustrate this. The atomic positions obtained from the refinements of the intermediates $\text{Na}_{3x}\text{RE}_{2-x}\text{Cl}_6$ are presented in Table 7.

At composition $x(\text{NdCl}_3) = 0.70$, as shown in Fig. 5, the first traces of the end member NdCl_3 become apparent, showing that the limiting composition of the homogeneity range lies between $x(\text{NdCl}_3) = 0.65$ and $x(\text{NdCl}_3) = 0.70$. Similarly, the other limiting composition, *i.e.* that on the NaCl-rich side, was found between $x(\text{NdCl}_3) = 0.50$ and $x(\text{NdCl}_3) = 0.55$. Contrary to the assessments of Seifert *et al.*¹¹ and Sato *et al.*,¹⁰ the solid solution in this system was observed to be stable at room temperature, rather than exclusively at elevated temperatures.

The stability of the solid solution at elevated temperatures was moreover investigated through quenching experiments, where three samples at compositions $x(\text{NdCl}_3) = 0.6, 0.625$ and 0.65 were heated up to 773 K and subsequently quenched in a water bath to preserve the crystal structures stable at high temperatures. These experiments showed that at $T = 773$ K, the crystal structure was still that of the single-phase solid solution. Furthermore, to rule out kinetic effects that limit the formation of the solid solution, we performed a synthesis experiment at $x(\text{NdCl}_3) = 0.75$ with two different heating durations (48 h and 96 h). No appreciable difference was observed between the two experiments, thus we conclude that 48 h is enough time for the synthesis experiment to reach thermodynamic equilibrium.

The progression of the cell volume of the intermediate compound $\text{Na}_{3x}\text{Nd}_{2-x}\text{Cl}_6$ is shown in Fig. 7 as a function of composition, and the values are reported in Table 6. On the left side of the single-phase region (*i.e.* from $x(\text{NdCl}_3) = 0.55$ – 0.65), a mixture of NaCl and $\text{Na}_{3x}\text{Nd}_{2-x}\text{Cl}_6$ is found, and the solid solution reaches the volume at its limiting composition. On the right side of the solubility range, a mixture of NdCl_3 and $\text{Na}_{3x}\text{Nd}_{2-x}\text{Cl}_6$ is found, but the size of the unit cell of the intermediate keeps shrinking as the NdCl_3 fraction increases. We would expect the volume of the intermediate compound to remain constant and equal to that at the limiting composition of the homogeneity range instead. The reason for this is as of yet

Fig. 2 Crystal structure of the $\text{Na}_{0.335}(\text{Na}_{0.168}\text{Nd}_{1.832})\text{Cl}_6$ compound obtained in this work viewed along the c -axis, with the elements Na, Nd and Cl indicated in yellow, orange and green respectively. The corresponding atomic parameters are listed in Table 7.

not known, and should be subjected to further investigation. As shown before in Fig. 4 and 5, several samples in the NaCl–NdCl₃ system were measured with synchrotron-XRD ($\lambda = 0.7653 \text{ \AA}$), labelled (sXRD) in Fig. 7, while others were measured by conventional laboratory XRD. The aim of the synchrotron experiments was to investigate the possible presence of end-members

towards the limiting compositions, *i.e.* $x(\text{NdCl}_3) = 0.55$ and 0.7 , given the higher resolution of s-XRD compared to lab-XRD, as well as obtain a high-resolution XRD of the single-phase Na_{3x}Nd_{2-x}Cl₆. The results of the synchrotron-XRD are very similar to the measurements carried out using lab XRD, confirming the reliability of the results.

The phase diagram has then been optimized based on the experimental DTA data from Sato *et al.*,¹⁰ shown in solid black circles in Fig. 6. The data from Sato *et al.* largely agree with the work of Seifert *et al.*,⁶¹ with the exception of the peritectic equilibrium. Seifert *et al.* measured two sub-liquidus equilibria between $x(\text{NdCl}_3) = 0.5$ and $x(\text{NdCl}_3) = 0.95$, whereas Sato *et al.* only measured one. This single peritectic equilibrium was also reported by Igarashi *et al.*⁹ and Sharma *et al.*⁸ Moreover, the work of Sharma *et al.* and Igarashi *et al.* reported the eutectic equilibrium up to $x(\text{NdCl}_3) = 0.8$, while Sato *et al.* and Seifert *et al.* reported the eutectic up to $x(\text{NdCl}_3) = 0.5$ and 0.6 , respectively. A possible explanation for the fact that Sharma *et al.* and Igarashi *et al.* measured the eutectic equilibrium up to higher NdCl₃ content could be a contamination (Sharma *et al.* report a minor NdOCl contamination), or a sub-cooling effect (Igarashi *et al.* analysed the measured cooling curves). Another explanation could be that the kinetics of formation of the solid solution is slow, meaning that if previous authors measured with high heating rates, they could potentially observe metastable phases in the system.

Additionally, the limits of the homogeneity range and the stability at room temperature of the intermediate Na_{3x}Nd_{2-x}Cl₆ have been included in the optimisation using the experimental

Table 6 Refined lattice parameters of the Na_{3x}RE_{2-x}Cl₆ phase in all investigated samples in the NaCl–RECl₃ (RE = Nd, Ce) systems, also shown in Fig. 7

Fig. 4 Profile refinement of the sXRD ($\lambda = 0.7653 \text{ \AA}$) at $x(\text{NdCl}_3) = 0.623$ in the NaCl–NdCl₃ system, showing the single phase Na_{0.335}(Na_{0.168}Nd_{1.832})Cl₆. The observed intensity (red circles) is shown alongside the calculated intensity (black line), and the difference between the two is shown (blue line). The angles at which reflections occur, *i.e.* the Bragg positions, are shown as well (green, vertical lines).

Fig. 5 Profile refinement of the sXRD ($\lambda = 0.7653 \text{ \AA}$) at $x(\text{NdCl}_3) = 0.70$ in the NaCl–NdCl₃ system, with phases Na_{0.304}(Na_{0.152}Nd_{1.848})Cl₆ and NdCl₃¹³ included in the refinement. The zoomed part of the figure shows the distinct separation of the Na_{3x}Nd_{2-x}Cl₆ peak (left) and the NdCl₃ peak (right). The observed intensity (red circles) is shown alongside the calculated intensity (black line), and the difference between the two is shown (blue line). The angles at which reflections occur, *i.e.* the Bragg positions, are shown as well (green, vertical lines).

data obtained in this work. The mixing enthalpy of this system has been measured by Gaune-Escard *et al.*⁶² at $T = 1124 \text{ K}$ and has been optimized based on these experimental data. The calculated mixing enthalpy of this system is presented in Fig. 9. The intermediate compound Na_{3x}Nd_{2-x}Cl₆ has been included in the thermodynamic model as a solid solution with NaCl and NaNd₂Cl₇ (corresponding to Na_{0.571}(Na_{0.286}Nd_{1.714})Cl₆ at $x(\text{NdCl}_3) = 0.66$) as end-members to account for the limiting compositions of the solubility range.

3.2.2 NaCl–CeCl₃. Similarly, the salt system NaCl–CeCl₃ has been investigated experimentally by various authors in the literature. Most authors have interpreted the system as a simple binary eutectic system,^{63–66} with Storonkin *et al.*⁶⁷ suggesting solubility of NaCl in a hypothetical low-temperature polymorphic phase of CeCl₃. Since CeCl₃ does not have a low-

temperature phase, that interpretation is discarded. Krämer and Meyer (1990)⁶⁸ and Lissner *et al.* (1992)¹² reported single-crystal studies of Na_{0.76}(Na_{0.38}Ce_{1.62})Cl₆ and Na_{0.698}(Na_{0.35}Ce_{1.65})Cl₆, respectively, again corresponding to a general stoichiometry of Na_{3x}Ce_{2-x}Cl₆ (space group $P6_3/m$). Seifert *et al.*¹¹ suggested, based on DTA and XRD, that a solid solution between CeCl₃ and an intermediate compound of composition Na₃Ce₅Cl₁₈ existed.

In addition to the data found in the literature, an experimental investigation of the intermediate compound Na_{3x}Ce_{2-x}Cl₆ was performed, like in the NaCl–NdCl₃ system, mostly to gain further insight into the composition of the intermediate and possible existence of a homogeneity range. Synthesis experiments at several compositions were performed to identify the solubility limits of this intermediate compound.

Fig. 6 Phase diagram of the NaCl–NdCl₃ system calculated with the thermodynamic model presented in this work. Experimental data from Sato *et al.*¹⁰ (closed black circles), Igarashi *et al.*⁹ (open blue squares), Sharma *et al.*⁸ (open upward green triangles) and Seifert *et al.*⁶¹ (open downward red triangles).

A single-phase intermediate compound was found at compositions $x(\text{CeCl}_3) = 0.60, 0.625$ and 0.65 , while NaCl was observed at compositions $x(\text{CeCl}_3) \leq 0.55$ and CeCl₃ was observed at compositions $x(\text{CeCl}_3) \geq 0.70$. Based on these results, we conclude that the limiting concentrations of this solid solution are between $x(\text{CeCl}_3) = 0.55$ and 0.60 on the NaCl-rich side, and $x(\text{CeCl}_3) = 0.65$ and 0.70 on the CeCl₃-rich side. The progression of the cell volume of the intermediate compound Na_{3x}Ce_{2-x}Cl₆, obtained from the refinements performed in this work, is shown in Fig. 7 and reported in Table 6. The compositions at which a single phase solid solution is observed obey the expected linear trend. Furthermore, like in the Na_{3x}Nd_{2-x}Cl₆ intermediate, the limiting composition on the left side of the solubility range shows that the cell volume reaches a maximum at compositions $x(\text{CeCl}_3) \leq$

Fig. 7 Cell volumes calculated from the profile refinements carried out in this work in the NaCl–RECl₃ (RE = Ce, Nd) systems. The data are both from synchrotron XRD and lab XRD, and the results obtained with these techniques are in good agreement with each other. A linear trend is visible in the single-phase solid solution following the insertion of the Na cation in the interstitial sites of the Na_{3x}RE_{2-x}Cl₆ crystal structure. The refined values are also given in Table 6.

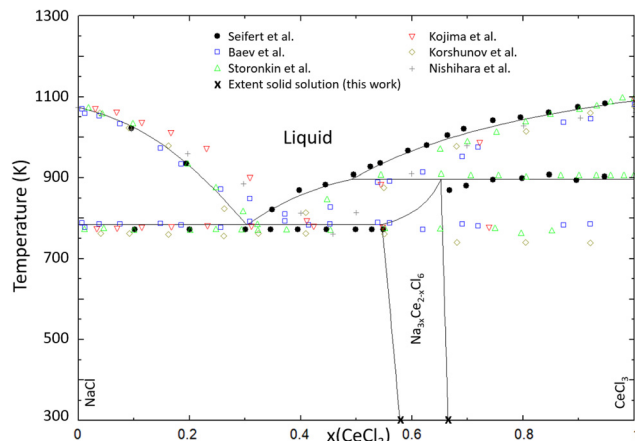

Fig. 8 Phase diagram of the NaCl–CeCl₃ system calculated with the thermodynamic model presented in this work. Experimental data from Seifert *et al.*¹¹ (closed black circles), Baev *et al.*⁶³ (open blue squares), Storonkin *et al.*⁷⁰ (open upward green triangles), Kojima *et al.*⁶⁶ (open downward red triangles), Korshunov *et al.*⁶⁴ (open gold diamonds) and Nishihara *et al.*⁶⁵ (grey pluses).

0.59. The same trend in the cell volume decreasing beyond the solubility limit of the rare earth chloride (that was also seen in the NaCl–NdCl₃ system), is observed here.

The NaCl–CeCl₃ thermodynamic model was optimized based on the DTA data from Seifert *et al.*¹¹ The measurement of the eutectic equilibrium past $x(\text{CeCl}_3) = 0.55$ in the other sources could be due to contaminations. Kojima *et al.*⁶⁶ and Nishihara *et al.*⁶⁵ report CeCl₃ purities $\leq 98\%$, and Storonkin *et al.*⁶⁷ measured what they interpret as a polymorphic transition in CeCl₃, which is an indication that they also had impurities in their CeCl₃ batch. Baev *et al.*⁶³ and Korshunov *et al.*⁶⁴ do not specify their measurement method or end-member purity, so it is difficult to say what could have gone wrong.

The extent and stability of the intermediate compound Na_{3x}Ce_{2-x}Cl₆ along with its solubility range was optimized based on the experimental data obtained in this work. The phase diagram of this system is presented in Fig. 8. The mixing enthalpy of this system was optimized based on the experimental data from Papatheodorou *et al.*⁶⁹ and is shown in Fig. 9. Like in the NaCl–NdCl₃ system, the intermediate compound Na_{3x}Ce_{2-x}Cl₆ has been included in the thermodynamic model as a solid solution between NaCl and NaCe₂Cl₇ end-members, with again an arbitrary destabilization term of the NaCl end-member of $+5000 \text{ J mol}^{-1}$.

3.2.3 Simulant chemistry in NaCl–MCl₃ systems. Before an assessment of the simulant representativeness can be made, the melting behaviour of the systems NaCl–UCl₃ and NaCl–PuCl₃ must be addressed. The system NaCl–UCl₃ has been investigated experimentally by Kraus *et al.*⁷¹ Sooby *et al.*⁴⁰ and Yingling *et al.*³⁵ The former reported the use of thermal analysis to obtain their results without further specifying their measurement method, whereas Sooby *et al.* and Yingling *et al.* used DSC. Both Kraus *et al.* and Sooby *et al.* interpret this system as a simple binary eutectic system. Yingling *et al.*,

Fig. 9 Calculated mixing enthalpies of the NaCl–MCl₃ (M = Ce, Nd, U, Pu) systems at $T = 1125$ K using the thermodynamic model presented in this work (NaCl–NdCl₃ and NaCl–CeCl₃), by Yingling *et al.*³⁵ (NaCl–UCl₃) and by Dumaire *et al.*²⁸ (NaCl–PuCl₃). Experimental data from Gaune-Escard *et al.*⁶² (NaCl–NdCl₃, open black circles) at $T = 1124$ K, Papatheodorou *et al.*⁶⁹ (NaCl–CeCl₃, open downward green triangles) at $T = 1118$ K and Matsuura *et al.*⁷² (NaCl–UCl₃, open blue upward triangles) at $T = 1113$ K. Data of the NaCl–PuCl₃ system (open red squares) were estimated using the method of Davis and Rice.¹⁴

however, suggest that an intermediate compound with the composition NaU₂Cl₇ (or Na₃U₅Cl₁₈) exists at elevated temperatures, based on their XRD measurements. Yingling *et al.* fit their thermodynamic model to the liquidus and eutectic equilibria of Kraus *et al.* and Sooby *et al.*, rather than those they measured themselves. Given the results obtained in this work in the NdCl₃ and CeCl₃ systems, we hypothesize that a similar homogeneity range could exist (*i.e.* Na_{3x}U_{2-x}Cl₆), although it might be stable only at high temperatures to match with the DSC data. Complementary studies are needed to verify this hypothesis. In this work, the assessment of Yingling *et al.* is largely retained, with a slight re-optimization to account for a difference in the end-members thermodynamic functions: Yingling *et al.* use both UCl₃ and U₂Cl₆ as end-members, which is not the case in this work.

The available experimental data for the NaCl–PuCl₃ system is much less abundant than for the other NaCl–MCl₃ systems (M = Ce, Nd, U). Bjorklund *et al.*⁵³ used a combination of thermal analysis (TA) and DTA to investigate the system, and concluded that it is a simple binary eutectic system with no intermediates or solid solubility. Dumaire *et al.*²⁸ presented a thermodynamic assessment of this system using the same formalism as used in this work. Their assessment of this binary system is therefore retained here as well. However, given the similarities between the NdCl₃ and PuCl₃ systems, the existence of a similar intermediate (Na_{3x}Pu_{2-x}Cl₆) needs to be explored by dedicated experiments.

The representativeness of the selected simulants in the NaCl–MCl₃ systems is shown in Fig. 10. In section 4.2, this study will be expanded by adding the comparison with the MgCl₂–MCl₃ (M = Ce, Nd, U, Pu) systems. Fig. 10 shows that the liquidus of the NaCl–PuCl₃ system is very close to that of

Fig. 10 Calculated phase diagrams of the systems NaCl–NdCl₃ (solid black line) and NaCl–CeCl₃ (dashed blue line), for which the thermodynamic models were developed in this work, and NaCl–UCl₃ (dashed red line) using the thermodynamic model of Yingling *et al.*³⁵ slightly altered to account for the different end-members. The models are compared to the experimental data on the NaCl–PuCl₃ system (open black circles) presented by Bjorklund *et al.*⁵³

Table 8 Eutectic equilibria in the NaCl–MCl₃ (M = Ce, Nd, U, Pu) systems as calculated with the thermodynamic models presented in this chapter

System	x_1	T_1 (K)	Source
PuCl ₃	0.385	725	Dumaire <i>et al.</i> ²⁸
NdCl ₃	0.355	718	This work
CeCl ₃	0.303	778	This work
UCl ₃	0.337	794	This work

the NaCl–NdCl₃ system. The systems NaCl–CeCl₃ and NaCl–UCl₃ show a similar slope of the liquidus to the PuCl₃ and NdCl₃ systems, but the difference in melting point between these simulants and PuCl₃ leads to a significant deviation of the melting temperature. The observed eutectic composition is similar for all four systems, as shown in Table 8. The eutectic composition and temperature of the NaCl–NdCl₃ system is closest to that of the NaCl–PuCl₃ system, though the latter can be once more explained by the aforementioned difference in melting point of the end-members.

4 Modelling NaCl–MgCl₂–MCl₃ (M = Ce, Nd, U, Pu) systems

4.1 Binary systems

As mentioned previously, the thermodynamic model of the NaCl–MgCl₂ system was taken from a previous work.¹⁸ The thermodynamic models of the systems MgCl₂–MCl₃ (M = Ce, Nd, U, Pu) are presented in this section, and were optimized based on the available data in the literature.

All systems MgCl₂–MCl₃ (M = Ce, Nd, U, Pu) modelled in this section are simple binary eutectic systems, with no

reported intermediates or solid solubility. The $\text{MgCl}_2\text{-NdCl}_3$ system has been investigated experimentally by Vogel *et al.*⁷³ using DTA. Sun *et al.*⁷⁴ measured the $\text{MgCl}_2\text{-CeCl}_3$ system using thermal analysis, without further specifying their measurement technique. The system $\text{MgCl}_2\text{-UCl}_3$ has been investigated by Desyatnik *et al.*⁷⁵ using differential thermal analysis (DTA), and they did not detect any solid solubility using XRD. Finally, the $\text{MgCl}_2\text{-PuCl}_3$ system has been modeled based on the experimental investigation by Johnson *et al.*⁷⁶ In the absence of experimental mixing enthalpy data for any of the systems, the mixing enthalpy of these systems has been estimated with the method of Davis and Rice.¹⁴

The systems $\text{MgCl}_2\text{-UCl}_3$ and $\text{MgCl}_2\text{-PuCl}_3$ have been modelled previously by Beneš *et al.*³¹ and are incorporated in the JRCMSD.³¹ In order to have our thermodynamic model agree with the estimated mixing enthalpy data, these systems have been reoptimized in this work. The phase diagrams of the systems $\text{MgCl}_2\text{-CeCl}_3$, $\text{MgCl}_2\text{-UCl}_3$, $\text{MgCl}_2\text{-NdCl}_3$ and $\text{MgCl}_2\text{-PuCl}_3$ are presented in Fig. 11, 12, 13 and 14, respectively. The calculated mixing enthalpies of these systems are given in Fig. 15, along with the estimated data using the method of Davis and Rice. The CALPHAD model reproduces the experimental phase diagram data well, as well as the estimated mixing enthalpies for the systems.

4.2 Simulant chemistry in $\text{MgCl}_2\text{-MCl}_3$ systems

With the optimized phase diagrams in Fig. 11–14, we can continue the assessment of the simulant of choice in this work. Fig. 16 shows the comparison between the experimental data for the $\text{MgCl}_2\text{-PuCl}_3$ system, and the thermodynamic models for the $\text{MgCl}_2\text{-MCl}_3$ ($M = \text{Ce, Nd, U}$) systems, like in section 3.2.3 for the NaCl-MCl_3 ($M = \text{Ce, Nd, U, Pu}$) systems. Similar to the aforementioned systems with NaCl, the difference in melting point of the MCl_3 ($M = \text{Ce, U}$) end-member causes a difference in melting behaviour compared to the PuCl_3 system on the MCl_3 -rich side of the phase diagram, which is not the

Fig. 12 Phase diagram of the $\text{MgCl}_2\text{-UCl}_3$ system calculated with the thermodynamic model presented in this work, compared to the experimental data from Desyatnik *et al.*⁷⁵

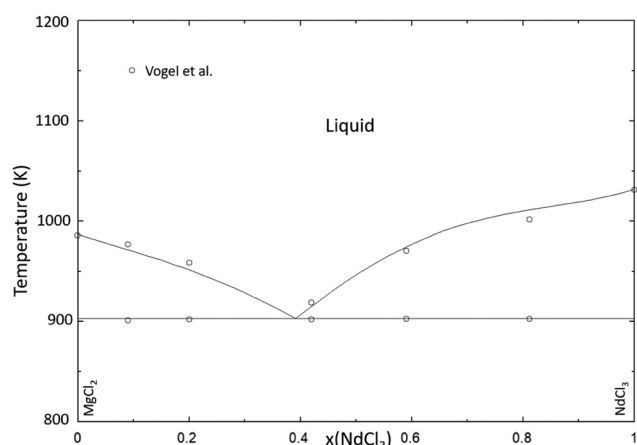

Fig. 13 Phase diagram of the $\text{MgCl}_2\text{-NdCl}_3$ system, calculated with the thermodynamic model presented in this work and compared to the experimental data from Vogel *et al.*⁷³

Fig. 11 Phase diagram of the $\text{MgCl}_2\text{-CeCl}_3$ system, calculated with the thermodynamic model presented in this work and compared to the experimental data from Sun *et al.*⁷⁴

Fig. 15 Mixing enthalpy of the $\text{MgCl}_2\text{-MCl}_3$ systems ($M = \text{Ce, Nd, U, Pu}$) calculated at $T = 1123 \text{ K}$, compared to data estimated using the method of Davis and Rice.¹⁴

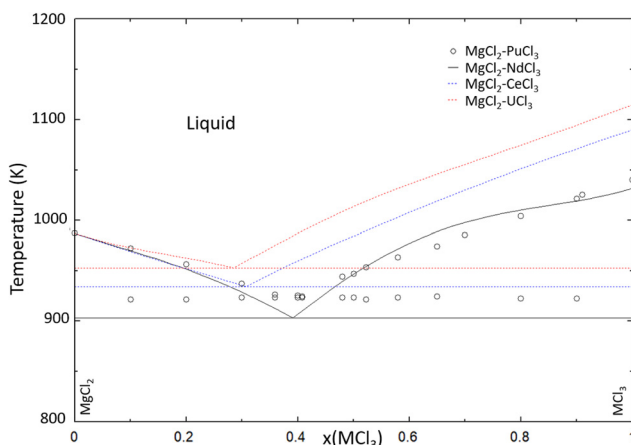

Fig. 16 Calculated phase diagrams of the systems $\text{MgCl}_2\text{-NdCl}_3$ (solid black line), $\text{MgCl}_2\text{-CeCl}_3$ (dashed blue line) and $\text{MgCl}_2\text{-UCl}_3$ (dashed red line) compared to the experimental data on the $\text{MgCl}_2\text{-PuCl}_3$ system (open black circles) presented by Johnson *et al.*⁷⁶

case for the NdCl_3 system. The eutectic compositions and temperatures of the $\text{MgCl}_2\text{-MCl}_3$ systems are given in Table 9. This table shows that while the eutectic temperature of the CeCl_3 system is marginally closer to that of the PuCl_3 system, the composition of the NdCl_3 system is almost identical to that of the PuCl_3 system.

Table 9 Eutectic equilibria in the $\text{MgCl}_2\text{-MCl}_3$ ($M = \text{Ce, Nd, U, Pu}$) systems as calculated with the thermodynamic models presented in this chapter

System	x_1	T_1 (K)
PuCl_3	0.382	922
NdCl_3	0.383	906
CeCl_3	0.308	934
UCl_3	0.285	953

4.3 Ternary systems

From the assessed binary systems, extrapolations to ternary systems $\text{NaCl-MgCl}_2\text{-MCl}_3$ ($M = \text{Ce, Nd, U, Pu}$) have been made without the addition of ternary excess parameters. This was done because there are no experimental data in the ternary systems available to the best of our knowledge, and to be con-

Fig. 17 Projected liquidus surface of the $\text{NaCl-MgCl}_2\text{-NdCl}_3$ system, calculated with the thermodynamic model presented in this work. Phases A–H listed on the ternary diagram are the primary crystallization phases. Phases listed are NaCl (A), Na_6MgCl_8 (B), Na_2MgCl_4 (C), NaMgCl_3 (D), $\text{Na}_2\text{Mg}_3\text{Cl}_8$ (E), MgCl_2 (F), NdCl_3 (G) and $\text{Na}_3\text{xNd}_{2-x}\text{Cl}_6$ (H). The calculated ternary eutectic equilibria are presented in Table 10.

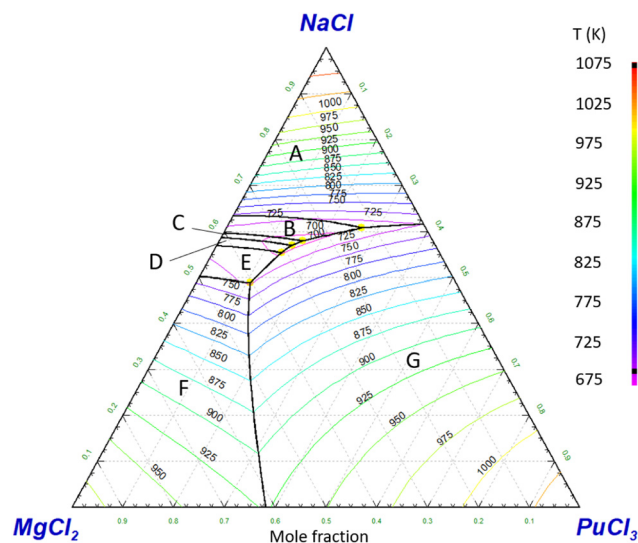

Fig. 18 Projected liquidus surface of the $\text{NaCl-MgCl}_2\text{-PuCl}_3$ system, calculated with the thermodynamic model presented in this work. Phases A–G listed on the ternary diagram are the primary crystallization phases. Phases listed are NaCl (A), Na_6MgCl_8 (B), Na_2MgCl_4 (C), NaMgCl_3 (D), $\text{Na}_2\text{Mg}_3\text{Cl}_8$ (E), MgCl_2 (F) and PuCl_3 (G). The calculated ternary eutectic equilibria are presented in Table 10.

sistent with the JRCMSD.³¹ The projected liquidus surface of the ternary systems NaCl-MgCl₂-NdCl₃ and NaCl-MgCl₂-PuCl₃ are presented in Fig. 17 and 18, respectively.

As seen in Fig. 17 and 18, the projected liquidus surface of the NaCl-MgCl₂-NdCl₃ and NaCl-MgCl₂-PuCl₃ systems are similar. This is also seen in Table 10, in which the ternary equilibria are presented. Table 10 also shows that the number of ternary invariant compositions found using our thermodynamic model are different compared to those of Beneš *et al.* This is because in our model of the NaCl-MgCl₂ system, we used four intermediate compounds (Na₆MgCl₈, Na₂MgCl₄, NaMgCl₃ and Na₂Mg₃Cl₈), whereas Beneš *et al.* used two

(Na₂MgCl₄ and NaMgCl₃). However, the compositions and temperatures of the ternary invariant equilibria predicted by Beneš *et al.* are close to compositions at which our thermodynamic model also predicts invariant equilibria.

Furthermore, the liquidus projections of the ternary systems NaCl-MgCl₂-CeCl₃ and NaCl-MgCl₂-UCl₃ are presented in Fig. 19 and 20, respectively. The ternary invariant equilibria shown on the liquidus projections in these figures are also listed in Table 11, along with the predicted invariant equilibria by Beneš *et al.*³⁷ Like in Table 10, the difference in the number of invariant equilibria found by Beneš *et al.* and our model is explained by the different amount of intermediate compounds present in the models. Again, like in the NaCl-MgCl₂-PuCl₃

Fig. 19 Projected liquidus surface of the NaCl-MgCl₂-CeCl₃ system, calculated with the thermodynamic model presented in this work. Phases listed A–H on the ternary diagram are the primary crystallization phases at that composition. Phases listed are NaCl (A), Na₆MgCl₈ (B), Na₂MgCl₄ (C), NaMgCl₃ (D), Na₂Mg₃Cl₈ (E), MgCl₂ (F), CeCl₃ (G) and Na_{3x}Ce_{2-x}Cl₆ (H). The calculated ternary equilibria are presented in Table 11.

Fig. 20 Projected liquidus surface of the NaCl-MgCl₂-UCl₃ system, calculated with the thermodynamic model presented in this work. Phases listed A–H on the ternary diagram are the primary crystallization phases at that composition. Phases listed are NaCl (A), Na₆MgCl₈ (B), Na₂MgCl₄ (C), NaMgCl₃ (D), Na₂Mg₃Cl₈ (E), MgCl₂ (F), UCl₃ (G) and NaU₂Cl₇ (H). The calculated ternary eutectic equilibria are presented in Table 11.

0.520	0.433	0.047	731	MgCl ₂ + UCl ₃ + NaMgCl ₃

system, the invariant equilibria calculated by Beneš *et al.* agree with our thermodynamic model. Additionally, when comparing the liquidus surfaces of all NaCl–MgCl₂–MCl₃ (M = Ce, Nd, U, Pu) systems, it reinforces the notion that Nd is more accurate as a simulant for Pu than either Ce or U. The behaviour of CeCl₃ in the molten salt systems presented in this chapter is closer to that of UCl₃, hence Ce could be used as a simulant for U instead.

5 Summary

We demonstrate in this work, by comparing the phase diagrams of the NaCl–MCl₃ and MgCl₂–MCl₃ systems (M = Ce, Nd, U, Pu), that NdCl₃ is the most suitable simulant for the melting behaviour of multicomponent systems containing PuCl₃, while CeCl₃ is most adapted for UCl₃-based systems.

Furthermore, a structural investigation of the intermediate compounds in the NaCl–NdCl₃ and NaCl–CeCl₃ systems has been performed. The existence of the intermediate compound Na_{3x}RE_{2–x}Cl₆ (RE = Ce, Nd) has been found as well as the solubility limits. This solid solubility has been included in the re-assessment of the thermodynamic models. This solid solution is not included in the existing models for the systems NaCl–UCl₃ and NaCl–PuCl₃ by Yingling *et al.*³⁵ and Dumaire *et al.*,²⁸ respectively, but further experimental investigation is recommended to investigate the possible intermediate compounds Na_{3x}An_{2–x}Cl₆ (An = U, Pu) in view of the strong similarities between the actinide and lanthanide systems discussed here.

Moreover, the models for the simple binary eutectic systems MgCl₂–MCl₃ (M = Ce, Nd, U, Pu) have been optimized based on the experimental data reported in the literature, as well as the estimated mixing enthalpies using the method of Davis and Rice. Finally, ternary extrapolations to the systems NaCl–MgCl₂–MCl₃ (M = Ce, Nd, U, Pu) have been made and compared to values reported in the literature, showing a good

agreement between the two, confirming that in these higher order systems, NdCl₃ and CeCl₃ are the most suitable simulants for PuCl₃ and UCl₃ based salts, respectively.

Conflicts of interest
