Phthalimide-based sulfur transfer reagents for the preparation of biologically relevant trisulfides

Conrad N. A. Du,  Austin Sarker-Young, Meg Shieh,  Stephen Lindahl and Ming Xian *

Reactive sulfur species (RSS) are a class of biological sulfur compounds that play significant roles in various physiological processes. Among these, trisulfides (RSSSR) have been recognized for their unique biological activities such as antioxidation. However, there is still a lack of suitable methods for the preparation of biothiol and protein trisulfides that will enable a better understanding of trisulfide's roles in RSS biology. In this study, we developed and analyzed the use of phthalimide-based disulfide reagents to generate trisulfides from thiols found abundantly in physiologically relevant environments. This approach was tested on both small molecule and larger protein thiols. The results demonstrated that this method provides access to both biothiol- and protein-based trisulfides and may facilitate further exploration of the functions of trisulfides in biological systems.

Introduction

Reactive sulfur species (RSS) are a class of biologically existing sulfur containing compounds that play regulatory roles in various physiological processes. Representative RSS include hydrogen sulfide (H₂S), thiols (RSH), disulfides (RSSR), polysulfides (RSS_nSR), hydropersulfides (RSSH), S-nitrosothiols (RSNO), sulfenic acids (RSOH), *etc.* Among these species, organic polysulfides (R–S–S_n–S–R, *n* ≥ 1, R ≠ H), especially trisulfides (R–S–S–S–R), are naturally occurring in plants of the *Allium* genus (*e.g.* garlic). These trisulfides have been demonstrated to have antimicrobial, antioxidation, and anti-cancer activities and act as mediators in cellular signaling.^{1–4} Additionally, some natural products (*e.g.* calicheamicin and shishijimicin A) contain trisulfide linkages.^{5,6} In these molecules, the trisulfide moiety is critical for their biological activities. Trisulfides can also serve as the effective precursor of H₂S and RSSH, two established redox signalling compounds. It should be noted that only a small number of proteins are currently known to contain the trisulfide motif.^{7,8} However, the increased understanding of the roles of polysulfides in cellular signalling has suggested that the prevalence of protein trisulfides may be underestimated.⁸ For example, sulfide quinone oxidoreductase couples the oxidation of H₂S to the reduction of coenzyme Q₁₀ in the mitochondrial electron transport chain. Considering its active site contains two

cysteines linked by a trisulfide that participates in the mechanism of oxidizing H₂S,⁹ methods that can be used to construct protein trisulfides are necessary for better understanding their roles in RSS biology. However, such methods are still very limited.¹⁰

In organic synthesis, methods for the preparation of small molecule trisulfides have been reported.¹¹ Representative examples (Scheme 1) include (a) the reaction of Na₂S with two equivalents of Bunte salts;¹² (b) the nucleophilic reaction of persulfides with mono-sulfur-based electrophiles (such as RS-Ts, RS-Cl, *etc.*);^{13–15} and (c) the reaction of thiols with disulfide-based electrophiles (*e.g.* RSSCl generated *in situ* from another thiol).^{16,17} While these methods have been successfully used in the preparation of many organic trisulfides, the formation of trisulfides with small biologically relevant thiols, such as cysteine and glutathione (GSH), and –SH containing proteins in aqueous conditions are still lacking. A report by Nicolaou *et al.* revealed that a phthalimide-based disulfide reagent could be used to install a methyl trisulfide in the synthesis of complex natural products such as shishijimicin A (Scheme 1).⁶ Inspired by the fact that this reagent can install trisulfides on complex natural products, we hypothesized that phthalimide-based disulfides could be applied under biologically relevant conditions to react with biothiols and proteins. Additionally, cysteine-based phthalimide reagents would be useful for the preparation of cysteine-based trisulfides that would be suitable for biological investigations with trisulfides. Herein, we report the preparation of such reagents and their applications in the preparation of both small molecule trisulfides and protein trisulfides.

Results and discussion

Preparation of cysteine–phthalimide disulfide 2

N-Acetyl-L-cysteine methyl ester (NACMe) was chosen to prepare the phthalimide disulfide reagent 2, because 2 could be used to construct cysteine-based trisulfides. Synthesis of 2 (Scheme 2) began with treating phthalimide with sulfur monochloride (S_2Cl_2) to give *N,N'*-thiobisphthalimide 1 in a 74% yield. The treatment of *N,N'*-thiobisphthalimide with NACMe then produced 2 with a 72% yield. Reagent 2 is a white solid that can be stored at low temperatures (such as 0 °C) without noticeable degradation for months.

Scheme 2 Preparation of cysteine–phthalimide disulfide 2.

Optimization of conditions for trisulfide synthesis

Benzyl mercaptan (BnSH) was chosen as a model thiol to optimize trisulfide formation with reagent 2. As shown in Table 1, when a 1 : 1 ratio of 2 and BnSH was used, the desired trisulfide 3 was obtained in a 60% yield (entry 1). If excess thiol was used (entry 2), the yield dropped to 41%. This is likely because the unreacted BnSH can react with and consume the trisulfide product. On the other hand, the use of excess reagent 2 in the reaction was found to increase the yield of 3 to 85% (entries 3 and 4). Since both 2 equiv. and 1.5 equiv. of 2 gave similar results, we decided to use 1.5 equiv. of 2 in the following studies to examine the effect of different solvents on the reaction (entries 4–7). All organic solvents, including dichloromethane (DCM), acetonitrile (ACN), and methanol (MeOH), were found to work well, while the use of water led to a lower yield (60%). This could be attributed to 2 having low solubility in water. Aqueous miscible organic solvents, such as ACN, could be used to offset the solubility issue. Nevertheless, the reaction was still fairly productive in water, suggesting that trisulfide formation could occur with water soluble biothiols.

Scope of thiol substrates for trisulfide synthesis

After determining the optimal conditions for trisulfide synthesis, the scope of applicable thiols was evaluated (Table 2). In all cases with primary, secondary, tertiary, and aryl thiols, the treatment of 2 with the thiols produced trisulfide products in excellent yields. Interestingly with tertiary thiols, 0.5 equivalents of triethylamine (TEA) was necessary for >60% yields. We also tested two water soluble thiols, GSH and thioglucose, in this reaction. For these substrates, a solvent mixture of ACN– H_2O was needed, and the reactions afforded the desired trisulfide products in >70% yields.

Preparation of protein-based trisulfides

Having successfully prepared trisulfides with water soluble thiols GSH and thioglucose, we then investigated reagent 2's ability to form trisulfides with thiol-containing proteins. Bovine serum albumin (BSA) was freshly reduced and treated with 2 (10 equiv.) in phosphate buffer (pH 7.4) at 4 °C overnight. Next, the protein was purified by PD-10 column and

Table 1 Optimization of trisulfide synthesis with 2

subjected to MS analysis. As seen in Fig. 1, the cysteine-based trisulfide adduct was detected on the intact protein. We also observed up to five trisulfide adducts on BSA, as reduced BSA is known to contain up to five free thiols.¹⁸ Besides BSA, we also tested papain in this reaction, and the trisulfide modification was also observed (see Fig. S1 in the SI). This new method for the preparation of trisulfide-containing proteins may be used to enhance our understanding of protein polysulfides and their roles in biological systems.

Trisulfides as sulfane sulfur precursors in cells

Polysulfides belong to the sulfane sulfur family and are known precursors of persulfides and H₂S. Glutathione trisulfide and glucose tetrasulfide have previously been used to induce H₂S and persulfide formation in biologically relevant

Fig. 1 (a) The reaction scheme of BSA trisulfide formation. Deconvoluted mass spectra of (b) reduced BSA and (c) reduced BSA treated with 10 equiv. of **2**.

conditions.^{18,19} Considering trisulfides **9** and **10** are NACME hybrids of the aforementioned polysulfide reagents, we wondered if these trisulfides could also be used to increase sulfane sulfur levels in cells. To test this, HeLa cells were incubated with **9** or **10** (50 μM) for 30 min and then washed with PBS to remove excess trisulfides. Cells were then incubated with SSP4, a known fluorescent probe for sulfane sulfur, for 50 min and washed before being subjected to fluorescence imaging.²⁰ As shown in Fig. 2, a significant increase in fluorescence was observed in cells treated with **9** or Na₂S₃ (positive control) compared to cells with no treatment. Surprisingly, treatment with **10** did not result in a significant increase in fluorescence. This may be due to compound **10**'s weaker cell permeability or its weaker reactivity toward -SH nucleophiles as observed in its weaker H₂S release ability compared to compound **9** (as shown in Fig. S2). These results demonstrate that **9** can increase intracellular sulfane sulfur levels and may potentially be used for additional cellular applications in the future.

Comparing trisulfides' sulfur transfer ability

One of the pathways in which trisulfides can increase cellular sulfane sulfur levels is by inducing persulfidation. Essentially, trisulfides can undergo sulfur transfer reactions to release the S⁰ atom (*i.e.* the middle S atom) to the acceptor thiol and form persulfides such as GSSH. With a series of trisulfide compounds (**3–7** & **13**) in hand, we set to understand their structure–activity relationships as sulfur transfer reagents.

To model the sulfur transfer ability of trisulfides, we employed their reaction with phosphine compounds, which is known to reduce trisulfides to their respective disulfide.²¹ We also found that trisulfide **3** treated with triphenylphosphine (PPh₃) formed the disulfide and triphenylphosphine sulfide (S=PPh₃), further demonstrating that the middle S atom was transferred. To determine the sulfur transfer ability of

heating. Purification of products was accomplished by flash column chromatography and purified compounds showed a single spot on TLC. NMR spectra were measured on a Bruker high field NMR spectrometer (^1H at 400 MHz or 600 MHz, ^{13}C at 151 MHz) and are reported in parts per million (ppm) on the δ scale relative to CDCl_3 (δ 7.26 for ^1H , δ 77.16 for ^{13}C) and D_2O (δ 4.79 for ^1H). High resolution mass spectrometry analysis was performed by the Agilent 6230 TOF LC/MS (ESI), and the deconvoluted mass spectra of the proteins was obtained through Agilent Mass Hunter BioConfirm software.

General procedure for the synthesis of trisulfides

1.5 equivalents of reagent **2** was dissolved in DCM. Thiol (1 equivalent) was dissolved in DCM and added dropwise to the reaction solution for a final concentration of 40 mM with respect to the thiol. The reaction was stirred at room temperature for 2 hours and monitored by TLC. After 2 hours, solvent was removed by rotary evaporator, and crude material was purified by flash column chromatography. Pure trisulfide was dried under high vacuum and analysed by ^1H , ^{13}C NMR, and ESI-MS.

Bovine serum albumin trisulfide formation

Reduced BSA was prepared according to literature procedures.¹⁷ Briefly, BSA (150 mg) was added to 2.3 mL phosphate buffer (100 mM, 0.1 mM pentetic acid, pH 7.4). Mercaptoethanol (23 μL) was added to the mixture, and the mixture was incubated overnight in the dark at 4 $^\circ\text{C}$. The mixture was then purified by PD-10 column, and protein-containing fractions were quantified by Nanodrop. The most concentrated fraction yielded 0.64 mM of reduced BSA. A 28 mM stock solution of **2** in ACN was freshly prepared. 78 μL of the most concentrated fraction of reduced BSA was diluted in 404 μL phosphate buffer and treated with 18 μL of **2** stock solution for a final concentration of reduced BSA (100 μM) and **2** (1.0 mM). The reaction solution was incubated overnight at 4 $^\circ\text{C}$ in the dark in an Eppendorf tube. The reaction mixture was then purified by PD-10 column, with an aliquot from the most concentrated fraction (44 μM), diluted to 16 μM for MS analysis. An aliquot of the most concentrated fraction of reduced BSA was also diluted to 16 μM for MS analysis. Both samples were passed through a Jupiter 5 μM C4 300 \AA column with mobile phase ($\text{H}_2\text{O}/\text{ACN}$, 0.1% formic acid) for desalting during LC-MS-TOF analysis, and the deconvoluted mass spectra were obtained with the Agilent BioConfirm software.

Cell imaging

HeLa cells were cultured in DMEM/F12 (1:1) (Gibco, Invitrogen, #11330-032) medium supplemented with 10% fetal bovine serum (FBS) at 37 $^\circ\text{C}$, 5% CO_2 and seeded in a 48-well plate (ThermoFisher Scientific, #150687). After 48 hours (~85% confluency), media was aspirated, and cells were washed 2 \times with PBS. **9**, **10**, and Na_2S_3 were freshly prepared at 10 mM stocks in sterile PBS (Gibco, ThermoFisher Scientific, #10010072) and then diluted to 50 μM in Fluorobrite DMEM before being added to the cells. Cells were incubated for 30 min at 37 $^\circ\text{C}$, 5% CO_2 . Afterwards, the cells were washed

once with PBS and incubated with SSP4 (20 μM , 0.2% DMSO) and CTAB (100 μM , 0.5% EtOH) in Fluorobrite DMEM for 50 min at 37 $^\circ\text{C}$, 5% CO_2 . Cells were then washed 3 \times with PBS, suspended in Fluorobrite DMEM, and subjected to fluorescence imaging on the Keyence All-in-One Fluorescence Microscope (BZ-X810).

Initial rate kinetics of triphenylphosphine sulfide formation

Fresh stock solutions of trisulfide and triphenylphosphine (PPh_3) were prepared in CDCl_3 . In an NMR tube was added CDCl_3 , an aliquot of trisulfide stock solution, and an aliquot of PPh_3 stock solution for a final volume of 500 μL with a final concentration of trisulfide (2 mM) and PPh_3 (20 mM). The formation of triphenylphosphine sulfide was monitored by ^{31}P NMR over 1.5 hours, with an almost complete disappearance of trisulfide after 24 hours. The initial rate of formation of triphenylphosphine sulfide was calculated from the change in concentration of triphenylphosphine sulfide over the initial 1.5 hours.

Computational method for trisulfide conformer

Trisulfides of interest (3–5) were modeled by Avogadro 1.2.0. A systematic rotor search was performed on each trisulfide using Avogadro generating 243 conformers. The resulting conformers were analysed by molecular mechanics method MMFF94 and ranked by predicted energy levels. The 30 conformers with the predicted lowest energy by MMFF94 were each optimized using Gaussian 09. Their energy levels were then determined by DFT in the gas phase at the $\omega\text{B97XD}/6\text{-311G}(2\text{d,p})$ level of theory to determine the lowest energy. Frequency calculated were performed using keywords freq. It has been previously demonstrated that $\omega\text{B97XD}/6\text{-311G}(2\text{d,p})$ is a rigorous level of theory for polysulfide compounds.²²

Conclusions

Herein, we reported the preparation and evaluation of compound **2**, a phthalimide-based sulfur transfer reagent for the synthesis of cysteine trisulfides. Thiols applicable for trisulfide synthesis involve primary, secondary, and tertiary organic thiols and biothiols, including proteins. Considering trisulfides are sulfane sulfur transfer reagents, the effects of sterics on their persulfide donating ability was investigated by experimental and computational methods. This efficient method of using phthalimide-based disulfide reagents to induce trisulfide formation on both small molecules and proteins may help increase the understanding of the roles of these polysulfides in RSS biology.
