Nagelamide C (1), a dimeric pyrrole-imidazole alkaloid, exhibits antimicrobial and antibacterial activities. We demonstrate herein the first total synthesis of nagelamide C. This concise work was enabled by a series of significant transformations featuring: an imidazole benzylic Wittig olefination, a site selective bromination, and a regioselective trans-hydrostannylation/Stille coupling to construct a unique trisubstituted olefin. In addition, we show the original ¹³C NMR data of nagelamide C to be in error and revise the data.

Introduction

The nagelamide alkaloids, a small family of marine sponge derived metabolites, consist of 26 pyrrole 2-aminoimidazole natural products with monomeric or dimeric frameworks (for a comprehensive list, Q.V. Fig. S1 in ESI†). Their biosynthesis is generally rationalized through dimerization, rearrangement, or oxidation from the parent monomeric clathrodin (2), hymenidin (3), or oroidin (4).1 The structure of nagelamide C (1, Fig. 1) was disclosed by Kobayashi and coworkers in 2004, which was isolated in trace amount from extracts of the Okinawan marine sponge Agelas sp. (0.00032% yield from 1.3 kg wet sponge).² Structurally, 1 presents an asymmetric skeleton bearing a rare trisubstituted Z-olefin wherein two oroidin subunits are joined via a single C-C bond at C10 and C15'. Many nagelamide alkaloids have been found to exhibit biological activities, nagelamide C displayed antimicrobial and antibacterial activities against Gram-positive bacteria.2

The fascinating and intriguing structure of nagelamide alkaloids, containing cyclic guanidines, halogenated heterocycles, polar properties and nitrogen-rich skeletons, have been attracting synthetic chemists for decades.3 To date, however, only a few nagelamide alkaloids have been synthesized. In 2006, Horne et al. completed the first synthesis of nagelamide A (5) and D (6) featuring a biomimetic oxidative dimerization.⁴ Baran and coworkers accomplished a collective total synthesis of nagelamide E (7), ageliferin (8), and sceptrin (9). In 2009, Lovely and coworkers developed an elegant synthesis of putative nagelamide D, in which they found the synthetic sample

did not completely match to the originally isolated spectroscopic data, but it was in good consistency with Horne's synthetic data.⁶ Thus far, the correct structure of 6 still yet to be

confirmed. Recently, Tepe achieved the synthesis of nagelamide W (10). Lindel reported the only synthetic study of nagelamide C in 2010.8

Results and discussion

Our interest in synthesizing dimeric pyrrole-imidazole natural products led to an efficient synthesis of sceptrin. 9 The challenging structure and interesting activity of 1 drew our attention as synthetic target. As depicted in Scheme 1, a convergent strategy was designed, in which nagelamide C could be crosscoupled through vinylstannane 11b' and bromide 12. Based on its proven utility as a building block within the context of these alkaloids, we sought to incorporate functionalized imidazo[1,2-a]pyrimidine as a precursor of the 2-aminoimidazole motif. 10 Both 12 and 11b' could be accessed by imidazole formation or Pd-catalyzed coupling. A sequence of selective bromination followed by Wittig olefination from 15, 16 and 17 would rapidly construct 12. To retain Z-trisubstituted olefin geometry in the proposed Stille coupling,11 a challenging regioselective trans-hydrostannylation12 was required to properly set the stannane at C10 from the corresponding internal alkyne. The requisite alkyne could be traced back to Sonogashira coupling between 3-bromoimidazo[1,2-a]pyrimidine 13 and propargylamines 14/14'.

Our synthesis commenced with the key trans-hydrostannylation investigation. Known amide 18 was readily prepared through Sonogashira coupling from commercially available 13 and N-Boc propargylamine 14.13 A general hydrostannylation condition¹⁴ was initially performed (Table 1, entry 1). Exposure of 18 to Bu₃SnH/Pd(PPh₃)₂Cl₂ in DCM at ambient temperature afforded cis-hydrostannylation product 11a exclusively in excellent yield (92%). The ruthenium-catalyzed trans-hydrostannyla-

17

Scheme 1 Synthesis design.

tion protocol developed by Fürstner et al. 15 was next evaluated. Although the desired stannane 11b could be observed (12-23% yield), the outcome of the trans-hydrostannylation was confronted with poor regioselectivity. Catalysts such as tetrameric [Cp*RuCl]₄ and oligomeric [Cp*RuCl₂]_n favored formation of proximal isomer 11c and 11d (entries 2 and 3). Presumably, the mono-protected amine (-NHBoc) could form a hydrogen bond with the ruthenium species, 15d then drive trans-hydrostannylation in favor of proximal adduct 11c and 11d. Moreover, Cp*Ru(cod)Cl gave 11a and 11d as major products (entry 4), the cationic acetonitrile adduct [Cp*Ru(MeCN)₃]PF₆ and [CpRu(MeCN)₃]PF₆ provided cis-adduct 11a/11c in modest yields (entries 5 and 6). Accordingly, we devised that installing an additional Boc group on the propargyl amide might improve regioselectivity in two ways: (1) -NBoc2 lacks an H-bond donor, preventing intermolecular hydrogen bond formation, (2) increasing steric hindrance around C9 might favor the formation of distal adduct 11b'. Upon treatment of amide 18' (prepared from 13 and 14') with [Cp*RuCl]₄ (entry 7), the desired product 11b' was obtained as an inseparable mixture (50:20:30) with 11a' and 11d' in excellent yield. To our delight, [Cp*RuCl₂]_n polymer further improved regioselectivity of the transformation, and 11b' was isolated as a 2:1 mixture with 11d' in 89% yield on gram scale (entry 8). [Cp*Ru (MeCN)₃]PF₆ (entry 9), showed similar selectivity compare to [Cp*RuCl]4, while it's triflate salt (entry 10) provided no product. Ru-complexes such as [CpRu(MeCN)₃]PF₆, Cp*Ru (cod)Cl, $[Ru(benzene)Cl_2]_2$ as well as $[Ru(p-cymene)Cl_2]_2$ all provided cis-adduct 11a' as the major isomer in good yields (entries 11-14). Other literature approaches that could access trans-hydrostannylation product were also investigated. Both catalytic and stoichiometric Lewis acid dibutyl magnesium^{16a} decomposed starting material (entry 15), while zirconium mediated hydrostannylation provided mono-Boc protected 18 (entry 16). Only cis-adduct 11a' was obtained in 53% yield under radical conditions 16c (AIBN, entry 17). Switching to Pd (PPh₃)₂Cl₂, **11a**' was afforded in 93% isolated yield (entry 18).

With sufficient 11b' in hand, we turned our attention to the construction of bromide 12. Condensation of 2-aminopyrimidine 15 with 1,3-dichloroacetone 16 under reflux in THF gave the corresponding HCl salt 19, which underwent water elimination upon treatment with triphenylphosphine (PPh3) in acetonitrile at 85 °C for 16 h. The resulting precipitates were easily collected and washed with acetone to furnish pure phosphonium salt 20 in 56% yield over two steps. Due to the instability of imidazo[1,2-a]pyrimidines towards strong bases, optimization of the benzylic Wittig olefination proved challenging. Inorganic base such as n-BuLi, LiHMDS, NaOMe, etc. all led to the decomposition of starting material. NaH, KOt-Bu gave variable and unscalable results. Unlike conventional Wittig reactions where an aldehyde was usually set on the imidazole ring, olefinations using imidazole benzylic phosphonium salt are far less documented.¹⁷ After exhaustive experimentation (Scheme 2B, see ESI† for details), an organic base, 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) was found to be optimal, furnishing the desired olefin 21 in 72% yield as a

^a Reactions were carried out on 0.1 mmol scale (0.1 M), ratio in the crude reaction mixture was determined by ¹H NMR spectroscopy, 1,3,5-trimethoxylbenzene as internal standard. **18** and **18**' were prepared from *N*-Boc-propargylamine and *N,N*-diBoc propargylamine, respectively. ^b The product was isolated in gram scale, 2.4 equiv. *n*Bu₃SnH was used. ^c **18** was isolated as the product. ^d Isolated yield. DCM: dichloromethane, THF: tetrahydrofuran. NR: no reaction.

3:1 ratio of E/Z isomers which were easily separated on silica gel. In addition, when we subjected 3-bromoimidazole phosphonium salt to the same Wittig conditions, protodebromination was observed. Other attempted methods such as Julia-Kocienski olefination, Suzuki coupling/bromination, or crossmetathesis were fruitless (see ESI† for full details). It is noteworthy that a selective bromination on the imidazole ring of 21 was achieved utilizing N-bromosuccinimide (NBS) to provide 12 in excellent yield (92%) without any bromination observed on the E-olefin. This 4-step sequence could be executed on gram scale and required a single chromatographic purification.

With straight-forward access to the desired building blocks, we pursued the total synthesis of 1. Pd-catalyzed coupling of 12 and a 2:1 mixture of 11b'/11d' was achieved in the presence of 10 mol% CuI and 2 equiv. of CsF, 18 delivering 63% diene 22 and 26% 23 after chromatograph separation. Boc removal with

TFA followed by acylation with 2,3-dibromo-5-trichloroacetylpyrrole (24) in the same flask produced the corresponding bispyrrole. Polar 2-aminoimidazoles were unveiled following exposure to an excess of hydrazine hydrate, delivering nagelamide C in 51% yield. The ¹H NMR data for synthetic 1 was consistent with the reported ¹H NMR data (Table 2). However, ¹³C NMR data of our synthetic sample was not in agreement with the reported spectroscopic data, where significant discrepancies were shown on multiple carbons: C8', C9', C10, C10', C11, C11', and C15 (Table 3). Interestingly, the original ¹³C chemical shift of both C8 and C8' were reported as 37.40 ppm. We anticipated that since these two carbons are influenced by different chemical environment, their 13C chemical shifts are not likely the same. Besides the 1D & 2D NMR acquisition of synthetic 1, we also conducted two additional experimentations to further determine its structure. 1. Addition of trifluoroacetic acid directly to a solution of free base 1 in DMSO-

 d_6 led to clear observation of $in\ situ$ formation of nagelamide C TFA salt. 2. The $^1H^{-15}N$ HSQC and HMBC spectra assisted to characterize all nitrogen atoms and their correlation with related protons. Taken together, all these data supported our structural assignment.

On the other hand, we suspected the reported structure of nagelamide C might be an *E*-isomer at the C9–C10 olefin. To this end, the nagelamide C *E*-isomer (26) was quickly synthesized following the established route to 1. Stannane 11a' (Table 1, entry 18) was employed in the Stille coupling, and

diene 25 was isolated in 79% yield. Lastly, a sequence of Bocdeprotection, acylation, and pyrimidine deprotection in one pot provided 26 in 56% yield. Both ¹H and ¹³C NMR of 26 are inconsistent with natural nagelamide C's spectroscopic data. In the meantime, we communicated with the original isolation chemists in the Kobayashi group and copies of the ¹H and ¹³C NMR spectra of natural nagelamide C were shared with us. Gratifyingly, the original ¹³C NMR spectra aligned well with our synthetic spectra (see ESI† for the comparison). Thus, the original 13C NMR data was revised and the structure of nagelamide C was confirmed.

Conclusions

In conclusion, we have accomplished the first total synthesis of nagelamide C. This concise route (6 longest linear steps from 2-aminopyrimidine) features an imidazole benzylic Wittig olefination, a site selective bromination, and a regioselective trans-hydrostannylation/Stille coupling sequence. The bromide 12 developed for this synthesis has a common protected 2-aminoimidazole motif which could be conveniently used to access other nagelamide alkaloids. The 13C NMR data of nagelamide C was revised through alignment of our synthetic spectra with the original NMR spectra. Therefore, the structure of 1 was confirmed. We hope the lessons learned here will inform the structural confirmation of other nagelamide alkaloids in the context of total synthesis. Moreover, utilizing bromide 12 to access relevant nagelamide alkaloids are under investigation and will be reported in due course.

Author contributions

All authors have given approval to the final version of the manuscript. G.T. and T.J. conceptualized the work. G.T. performed the experiments and analyzed the data. L.N. conducted exploratory studies and edited the manuscript, T.J. directed the project. The manuscript is written by G.T.
