## Near-infrared luminescence from $\text{Li}_2\text{ZnGeO}_4:\text{Ln}^{3+}$ (Ln = Er, Tm, Ho)

 Nikola Bednarska-Adam,<sup>a</sup> Marta Kuwik,<sup>a</sup> Tomasz Goryczka,<sup>b</sup> Vitalii Ivanov,<sup>c</sup> Józef Dresner,<sup>d</sup> Wojciech A. Pisarski<sup>a</sup> and Joanna Pisarska<sup>a\*</sup>

In this work, ceramic compounds  $\text{Li}_2\text{ZnGeO}_4:\text{Ln}^{3+}$  (Ln = Er, Tm, Ho), belonging to the family of germanate olivines, were studied. The structural properties were examined using X-ray diffraction, scanning electron microscopy, IR and Raman spectroscopy. Near-infrared luminescence spectra showed that the bands located in the spectral range of 1400–2100 nm were due to the electronic transitions of lanthanide ions:  $^4\text{I}_{13/2} \rightarrow ^4\text{I}_{15/2}$  ( $\text{Er}^{3+}$ ),  $^3\text{H}_4 \rightarrow ^3\text{F}_4$  and  $^3\text{F}_4 \rightarrow ^3\text{H}_6$  ( $\text{Tm}^{3+}$ ), and  $^5\text{I}_7 \rightarrow ^5\text{I}_8$  ( $\text{Ho}^{3+}$ ). Decay curve analysis indicated that the near-infrared luminescence from the excited states of lanthanide ions in  $\text{Li}_2\text{ZnGeO}_4$  was relatively long-lived. The results suggest that germanate olivines  $\text{Li}_2\text{ZnGeO}_4:\text{Ln}^{3+}$  (Ln = Er, Tm, Ho) are promising inorganic phosphors and can be successfully used as ceramic sources emitting near-infrared radiation.

### Introduction

In recent years, near-infrared (NIR) luminescent materials,<sup>1–5</sup> with particular focus on NIR inorganic persistent phosphors,<sup>6,7</sup> have gained significant attention due to their numerous multifunctional applications. Recently published papers report interesting findings regarding the potential applications of NIR persistent phosphors in the third bio-imaging window (NIR-III). Xu and co-workers<sup>8–10</sup> suggested that NIR long persistent luminescence of erbium ions in inorganic phosphors such as garnet  $\text{Y}_3\text{Al}_2\text{Ga}_3\text{O}_{12}$  or perovskite  $\text{LaAlO}_3$  can be realized by utilizing efficient energy transfer from  $\text{Ce}^{3+}$  to  $\text{Er}^{3+}$  or  $\text{Cr}^{3+}$  to  $\text{Er}^{3+}$ , respectively. These inorganic phosphors exhibit long (>10 h) NIR persistent luminescence centered at approximately 1550 nm due to the  $^4\text{I}_{13/2} \rightarrow ^4\text{I}_{15/2}$  transition of erbium ions, operating in the NIR-III biological window. These aspects are particularly interesting for low-phonon inorganic matrices, especially germanate ceramics, due to their promising optical and dielectric properties.

In general, germanate-based ceramics are very attractive materials for modern visible and near-infrared optoelectronics. Doping with lanthanide ions ( $\text{Ln}^{3+}$ ) enables important multifunctional applications of germanate ceramics, including their use as inorganic phosphors in red-green-blue (RGB) technology. Phosphors of  $\text{ABGe}_2\text{O}_7$  (A = La or Y; B = Al or In) doped with  $\text{Er}^{3+}$ ,  $\text{Tb}^{3+}$ ,  $\text{Pr}^{3+}$  or  $\text{Tm}^{3+}$ , emitting red, green or blue light with

high color purity, are of interest for displays and lighting devices.<sup>11–14</sup>  $\text{Eu}^{3+}$ -doped germanate ceramics, such as  $\text{Zn}_2\text{-GeO}_4:\text{Eu}^{3+}$ ,  $\text{KNaGaGeO}_4:\text{Eu}^{3+}$ , and  $\text{Ba}_2\text{AGe}_2\text{O}_7:\text{Eu}^{3+}$  (A = Mg or Zn), are thermally stable, efficient red-emitting phosphors, which can be successfully applied to high-resolution and high-sensitivity accurate latent fingerprint detection, multi-mode anti-counterfeiting and white-LED applications.<sup>15–17</sup> Phosphors with the general formula  $\text{A}_2\text{B}_2\text{GeO}_7$  (where A = Ca or Sr; B = Al or Ga) doped with  $\text{Pr}^{3+}$  ions<sup>18,19</sup> and co-doped with  $\text{Pr}^{3+}/\text{Yb}^{3+}$  ions<sup>20</sup> may be applied for c-Si solar cells, biomedical imaging and dynamic multicolor anti-counterfeiting under UV irradiation. The energy transfer processes in germanate ceramics co-doped with  $\text{Dy}^{3+}/\text{Tm}^{3+}$  and  $\text{Tb}^{3+}/\text{Eu}^{3+}$  ions<sup>21,22</sup> have been studied in relation to their practical applications as white-light-emitting diodes. Phosphors, such as  $\text{Zn}_2\text{GeO}_4$ ,<sup>23</sup>  $\text{Ca}_2\text{Al}_2\text{Ge}_3\text{O}_{12}$ ,<sup>24</sup> and  $\text{La}_4\text{GeO}_8$ ,<sup>25</sup> co-doped with  $\text{Er}^{3+}/\text{Yb}^{3+}$  ions have been designed for fingerprint verification, anti-counterfeiting and luminescent thermometry. The influence of  $\text{Yb}^{3+}$  content on the up-conversion luminescence of  $\text{Er}^{3+}$  ions in  $\text{SrGe}_4\text{O}_9$  phosphors has also been examined in detail.<sup>26</sup> Further studies revealed that germanate ceramic materials co-doped with transition metal and lanthanide ions are also useful for a wide range of photonic applications, including c-Si solar cells, infrared detectors and long-wavelength NIR LED chips.<sup>27,28</sup>

Among the germanate ceramics, special attention has been paid to compounds with an olivine structure. The  $\text{AYGeO}_4$  (A = Na or Li) germanate olivines doped with  $\text{Eu}^{3+}$ ,  $\text{Sm}^{3+}$  or  $\text{Dy}^{3+}$  have been developed for potential applications in solid-state lighting.<sup>29–31</sup> The variation in the up-conversion luminescence of  $\text{LiYGeO}_4:\text{Er}^{3+}/\text{Yb}^{3+}$  phosphors with temperature has been also investigated for optical thermometers and anti-counterfeiting.<sup>32</sup> The results indicate that the modulation of emission color can

<sup>d</sup>Eurotek International, 02-726 Warsaw, Poland

be realized by changing the laser excitation power, temperature and pumping wavelength. Ceramics with the chemical formula  $\text{Li}_2\text{ZnGeO}_4$  belong to the same olivine-type germanate family. The energy band gap for  $\text{Li}_2\text{ZnGeO}_4$  calculated from the Kubelka–Munk equation and Tauc plot method is equal to 5.78 eV.<sup>33</sup> However, the data in the literature indicate that the optical properties of  $\text{Li}_2\text{ZnGeO}_4$  have been rarely studied. Recently, the published papers mainly focused on the luminescence of  $\text{Li}_2\text{ZnGeO}_4$  germanate ceramics doped with transition metal ions such as  $\text{Mn}^{2+}$  and  $\text{Cr}^{4+}$ . The experimental results suggest that  $\text{Mn}^{2+}$ -doped  $\text{Li}_2\text{ZnGeO}_4$  ceramics<sup>34,35</sup> are promising green-emitting phosphors in field-emission displays with high color purity, whereas  $\text{Cr}^{4+}$ -doped  $\text{Li}_2\text{ZnGeO}_4$  ceramics are recommended as efficient broadband NIR-II phosphors.<sup>36</sup> Factually, recent work on  $\text{Ln}^{3+}$ -doped germanate olivines was limited to  $\text{Li}_2\text{ZnGeO}_4$  with  $\text{Pr}^{3+}$ ,  $\text{Nd}^{3+}$  or  $\text{Gd}^{3+}$ , which exhibited enhanced persistent blue luminescence.<sup>37</sup> However, to date, the infrared emission properties of  $\text{Li}_2\text{ZnGeO}_4:\text{Ln}^{3+}$  have not been studied. Lastly, the emission properties of  $\text{NaYGeO}_4:\text{Tm}^{3+}$  powders in the range of 1300–1600 nm and 1600–2200 nm due to the  $^3\text{H}_4 \rightarrow ^3\text{F}_4$  and  $^3\text{F}_4 \rightarrow ^3\text{H}_6$  transitions of  $\text{Tm}^{3+}$  have been analyzed under 808 nm laser diode excitation.<sup>38</sup> At this moment, it should be also pointed out that  $\text{Nd}^{3+}/\text{Ho}^{3+}$  co-doped  $\text{NaLa}_9(\text{GeO}_4)_6\text{O}_2$  phosphors with an apatite structure have been proposed for infrared luminescence applications.<sup>39</sup>

The aim of this work is related to germanate olivines  $\text{Li}_2\text{ZnGeO}_4:\text{Ln}^{3+}$  emitting near-infrared radiation in the spectral range of 1400–2100 nm. Lanthanide ions playing an important role as optical dopants were limited to trivalent erbium, thulium and holmium due to their near-infrared luminescence bands located at about 1500 nm ( $\text{Er}^{3+}$ ), 1450/1800 nm ( $\text{Tm}^{3+}$ ) and 2000 nm ( $\text{Ho}^{3+}$ ), respectively. Luminescence bands corresponding to the  $^4\text{I}_{13/2} \rightarrow ^4\text{I}_{15/2}$  ( $\text{Er}^{3+}$ ),  $^3\text{H}_4 \rightarrow ^3\text{F}_4$  and  $^3\text{F}_4 \rightarrow ^3\text{H}_6$  ( $\text{Tm}^{3+}$ ), and  $^5\text{I}_7 \rightarrow ^5\text{I}_8$  ( $\text{Ho}^{3+}$ ) transitions of  $\text{Ln}^{3+}$  were analyzed. Our studies showed that the  $\text{Li}_2\text{ZnGeO}_4:\text{Ln}^{3+}$  germanate olivines are promising inorganic phosphors and attractive candidate for ceramic sources useful in near-infrared optoelectronics. Our intention was to study the infrared emission properties of  $\text{Ln}^{3+}$ -doped germanate olivines for the first time. The unique advantages of this study are the characterization of the near-infrared luminescence of  $\text{Er}^{3+}$ ,  $\text{Tm}^{3+}$  and  $\text{Ho}^{3+}$  ions in germanate ceramic systems in the range of 1400–2100 nm, which has not been examined and reported before, to the best of our knowledge.

## Experimental

$\text{Li}_2\text{Zn}_{(1-x)}\text{Ln}_x\text{GeO}_4:x\text{Ln}^{3+}$  ( $\text{Ln}^{3+} = \text{Er}^{3+}$ ,  $\text{Tm}^{3+}$  or  $\text{Ho}^{3+}$  with a concentration equal to 0.5 mol%) samples in the form of pellets were prepared using the high-purity initial reagents of ZnO (99.99%),  $\text{GeO}_2$  (99.99%), and  $\text{Li}_2\text{CO}_3$  (99.997%), and the appropriate lanthanide oxides of  $\text{Er}_2\text{O}_3$  (99.999%),  $\text{Tm}_2\text{O}_3$  (99.999%) or  $\text{Ho}_2\text{O}_3$  (99.999%) from Sigma-Aldrich Chemical Co. (St. Louis, MO, USA) *via* the conventional high-temperature solid-state reaction method. The appropriate amounts of raw materials were milled and homogenized in an agate mortar for 1 h with  $\text{C}_2\text{H}_5\text{OH}$  medium (POCH basic 96% pure). The ground

samples were calcined in a non-covered Pt crucible at 1100 °C/6 h in an air atmosphere. The calcination process was divided into two steps, *i.e.*, reaching the temperature of 800 °C/0.5 h, and then 1100 °C/10 min. The calcinated samples were ground again and divided into smaller batches. Pellets with a diameter of 10 mm were formed using a binder (PVA) and cold pressed at 375 MPa. Next, the pellets were subjected to heat treatment to remove the binder at 550 °C/2 h and cooled to room temperature. The samples were sintered at 1200 °C/5 h and cooled to room temperature. The sintering process included several steps of heating to 800 °C/1 h, then sintering for 15 min, heating to 1200 °C and sintering for 5 h.

To characterize the undoped and  $\text{Ln}^{3+}$ -doped ceramic samples, several measurements were performed, including XRD, SEM, transmittance, Raman and near-infrared emission spectroscopy. The nature of the studied samples was identified using a diffractometer (X'Pert-Pro, PANalytical, Eindhoven, The Netherlands). X-ray diffraction measurements were performed with  $\text{CuK}_{\alpha 1}$  and  $\alpha_2$  radiation. The microstructure of the samples was observed using a JSM6480 scanning electron microscope (SEM) along with JSM-7100F TTL LV (Jeol Ltd., Tokyo, Japan). Transmittance spectra were recorded on a Nicolet™ iS™ 50 IR spectrometer. Raman spectra were measured using a Thermo Scientific™ DXR™2xi Raman imaging microscope. Data were recorded with a 455 nm laser (the power 4 mW on samples). Near-infrared luminescence measurements were carried out using a Photon Technology International (PTI) Quanta-Master 40 (QM40) UV/VIS steady-state spectrofluorometer including a double 200 mm monochromator, an Xe lamp (75 W) as the light source, and Hamamatsu H10330B-75 and InGaAs detectors. The spectra were measured with a resolution of  $\pm 0.5$  nm. For the decay curve measurements, a pulsed tunable optical parametric oscillator (OPO) pumped by the third harmonic of an Nd:YAG laser (Opotek Opolette 355 LD, Carlsband, CA, USA) was used. The decay curves with an accuracy of  $\pm 0.5$   $\mu\text{s}$  were recorded using a PTI ASOC-10 USB-2500 oscilloscope (Horiba Instruments).

Absolute photoluminescence quantum yield was measured using a Petite integrating sphere (PTI Horiba Instruments), which is the standard accessory for QM40. It replaces the sample holder, and thus no modification of excitation or emission optics was required. The integration sphere had a powder or pellet holder inside it. The method applied used two-step luminescence measurement, with the excitation set to  $\lambda_{\text{exc}}$ . Firstly, the entire luminescence spectrum, including the scatter of excitation line around  $\lambda_{\text{exc}}$ , was recorded with the “active sample” in the pellet mount. In the second step, the same measurement was executed with the “reference sample”, which was prepared in the same way as the active sample, but without  $\text{Ln}^{3+}$  ions. This procedure guaranteed that all the conditions for sample and reference runs were as similar as possible. Both spectra were actively recorded with real-time emission correction. A QM40 EXCORR real-time excitation source intensity monitor was used to verify the stability of the Xe lamp source. Dark background subtraction before each run was also applied. All measurement conditions were kept identical in both runs with the exception of a neutral density filter to reduce

the intensity of the strong scattered band at  $\lambda_{\text{exc}}$  to keep the intensity of this band in the same order as the luminescence band of interest around  $\lambda_{\text{em}}$ . Then, the attenuation coefficient was carefully measured. The integral intensities of the scatter  $I(\lambda_{\text{exc}})$  band and luminescence with any possible trace of the scatter at  $I(\lambda_{\text{em}})$  for the active and reference samples were calculated and subtracted, respectively, yielding a good representation of the number of photons absorbed and emitted by the sample. The ratio of the latter to the former, corrected by the attenuation factor of the ND filter used resulted in the absolute quantum yield of the  $I(\lambda_{\text{em}})$  emission band.

## Results and discussion

The X-ray diffraction patterns of the undoped  $\text{Li}_2\text{ZnGeO}_4$  and lanthanide-doped  $\text{Li}_2\text{ZnGeO}_4:\text{Ln}^{3+}$  ( $\text{Ln} = \text{Er}, \text{Tm}, \text{Ho}$ ) germanate ceramics are presented in Fig. 1. All the diffraction peaks can be assigned to the  $\text{Li}_2\text{ZnGeO}_4$  ceramic compounds, which crystallize in a monoclinic lattice with the  $P2_1/n$  space group (ICDD PDF-4 database – card no. 00-038-1082). It is also well evident that  $\text{Ln}^{3+}$  doping had no effect on the crystalline structure and no additional phases related to impurities existed compared to the pure  $\text{Li}_2\text{ZnGeO}_4$  monoclinic phase. This suggests that  $\text{Ln}^{3+}$  ions well entered  $\text{Li}_2\text{ZnGeO}_4$  with an olivine structure.

Further studies using the SEM-BS images (Fig. 2) sensitive to the contrast of the chemical composition confirmed that no other phases, precipitation, or inclusions existed in the undoped and  $\text{Ln}^{3+}$ -doped ceramic samples. Similar to previously published results for  $\text{Li}_2\text{MgGeO}_4$  doped with  $\text{Pr}^{3+}$  and  $\text{Tm}^{3+}$  ions,<sup>40</sup> the objects shown in the SEM-BS images have an even shade of gray, suggesting that all the ceramic components reacted and only one crystalline phase of  $\text{Li}_2\text{ZnGeO}_4$  was formed.

Previous investigations on  $\text{Li}_2\text{ZnGeO}_4$  ceramics using Raman spectroscopy revealed that bands observed in the low frequency range below  $400\text{ cm}^{-1}$  correspond to the wagging and twisting vibrations of the  $\text{GeO}_4$  tetrahedra.<sup>41,42</sup> Fig. 3 shows the Raman spectrum measured in the higher frequency region, which

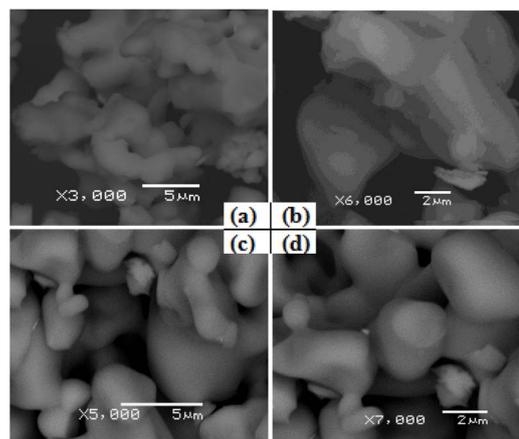

Fig. 2 Ceramic particles observed with SEM-BS images: (a) undoped sample and samples doped with (b)  $\text{Er}^{3+}$ , (c)  $\text{Tm}^{3+}$  and (d)  $\text{Ho}^{3+}$  ions.

consists of two groups of bands. These two groups are located in the frequency range of  $440\text{--}550\text{ cm}^{-1}$  and  $650\text{--}850\text{ cm}^{-1}$ , respectively. The first group of bands near  $442\text{ cm}^{-1}$ ,  $494\text{ cm}^{-1}$  and  $529\text{ cm}^{-1}$  is related to the bending vibrations of the  $\text{GeO}_4$  groups.<sup>33</sup> In the second group, the three bands located at about  $725\text{ cm}^{-1}$ ,  $752\text{ cm}^{-1}$  and  $820\text{ cm}^{-1}$  are due to the stretching vibrations of the  $\text{GeO}_4$  groups.<sup>43</sup> Based on previous results obtained for zinc germanate nanomaterials,  $\text{Zn}_2\text{GeO}_4$ , the Raman bands located at  $750\text{ cm}^{-1}$  and  $820\text{ cm}^{-1}$  were assigned to the symmetric and asymmetric stretching vibration of the Ge–O–Zn bond, respectively.<sup>44</sup>

Numerous near-infrared luminescent materials containing lanthanide and/or transition metal ions have been reported.<sup>1</sup> Among them, low-phonon germanate ceramics seem to be perspective emerging infrared luminescent materials for next-generation optoelectronic devices.<sup>45</sup> In particular, there has been a significant increase in the search for germanate-based materials emitting infrared radiation in the spectral range of  $1400\text{--}2100\text{ nm}$ .<sup>46,47</sup> Near-infrared laser sources are an attractive scientific topic due to their various fields of applications such as

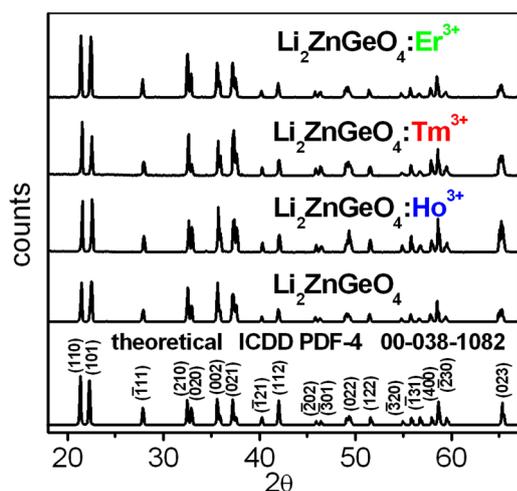

Fig. 1 X-ray diffraction patterns of  $\text{Li}_2\text{ZnGeO}_4$  and  $\text{Li}_2\text{ZnGeO}_4:\text{Ln}^{3+}$ .

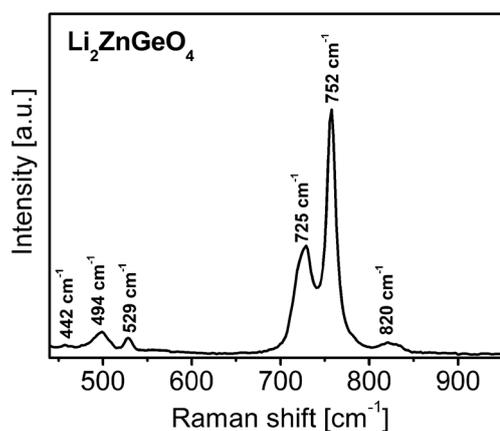

Fig. 3 Raman spectrum of germanate ceramics  $\text{Li}_2\text{ZnGeO}_4$ .

laser remote chemical sensing, medical surgery and atmospheric monitoring. They can be also applied as the main components in eye-safe laser radars and optical amplifiers. In this spectral region, materials doped with  $\text{Er}^{3+}$ ,  $\text{Tm}^{3+}$  and  $\text{Ho}^{3+}$  can emit infrared radiation due to their characteristic intra-configurational 4f–4f electronic transitions. Based on absorption and luminescence spectra measurements, the energy level diagram including main laser transitions at 1450 nm, 1550 nm, 1800 nm and 2000 nm was constructed for numerous germanate-based compounds doped with  $\text{Er}^{3+}$ ,  $\text{Tm}^{3+}$  and  $\text{Ho}^{3+}$ , which have been studied systematically by us in detail.<sup>48–54</sup> The near-infrared luminescence bands of the  $\text{Ln}^{3+}$  ions correspond to the  ${}^4\text{I}_{13/2} \rightarrow {}^4\text{I}_{15/2}$  ( $\text{Er}^{3+}$ ) transition located at 1550 nm, the  ${}^3\text{H}_4 \rightarrow {}^3\text{F}_4$  and  ${}^3\text{F}_4 \rightarrow {}^3\text{H}_6$  ( $\text{Tm}^{3+}$ ) transitions near 1450 nm and 1800 nm, and the  ${}^5\text{I}_7 \rightarrow {}^5\text{I}_8$  ( $\text{Ho}^{3+}$ ) transition at 2000 nm. They are schematically illustrated in the energy level diagram of  $\text{Ln}^{3+}$  ions shown in Fig. 4.

According to transmittance spectrum measurements, it is well known that the infrared band located near  $3400\text{ cm}^{-1}$  is due to the stretching vibrations of hydroxyl groups. The relatively high content of hydroxyl groups effectively quenches the emission from the excited states of  $\text{Ln}^{3+}$  ions in different compounds. This phenomenon is especially important for  $\text{Er}^{3+}$ ,<sup>55–57</sup>  $\text{Tm}^{3+}$ ,<sup>58</sup> and  $\text{Ho}^{3+}$  ions<sup>59</sup> in inorganic glasses emitting near-infrared radiation at 1550 nm ( $6450\text{ cm}^{-1}$ ), 1800 nm ( $5550\text{ cm}^{-1}$ ) and 2000 nm ( $5000\text{ cm}^{-1}$ ) because less than two vibrations of  $\text{OH}^-$  groups can effectively bridge the energy gaps between  ${}^4\text{I}_{13/2}$  and  ${}^4\text{I}_{15/2}$  ( $\text{Er}^{3+}$ ),  ${}^3\text{F}_4$  and  ${}^3\text{H}_6$  ( $\text{Tm}^{3+}$ ), and  ${}^5\text{I}_7$  and  ${}^5\text{I}_8$  ( $\text{Ho}^{3+}$ ), and quench the near-infrared emission. Structural transformation from glasses (completely amorphous) to glass-ceramic materials (partially crystallized) progressively results in a decrease in the number of hydroxyl groups with an increase in heat-treatment temperature.<sup>60</sup> Further systematic studies suggest that the increase in the photoluminescence intensity of the lanthanide ions with the calcination temperature is attributed to the removal of the hydroxyl groups.<sup>61</sup> Thus, the high-temperature sintering process ( $1200\text{ }^\circ\text{C}/5\text{ h}$ ) used for the

preparation of the  $\text{Li}_2\text{ZnGeO}_4:\text{Ln}^{3+}$  germanate ceramics, where Ln denotes Er, Tm or Ho (see Experimental section), can efficiently reduce the  $\text{OH}^-$  content. The results from the transmittance spectrum measurements given in Fig. 5 show that the IR band intensity near  $3400\text{ cm}^{-1}$  is extremely low and nearly invisible compared to our previous results for oxide and oxy-fluoride germanate glass systems based on  $\text{BaO-Ga}_2\text{O}_3\text{-GeO}_2$  (BGG), where the IR absorption coefficients,  $\alpha_{\text{OH}}$ , are close to  $0.25\text{ cm}^{-1}$  (0%  $\text{BaF}_2$ ) and  $0.020\text{ cm}^{-1}$  (10%  $\text{BaF}_2$ ), respectively.<sup>50</sup> This suggests that the presence of  $\text{OH}^-$  groups cannot make a substantial contribution to the luminescence quenching from the excited states of  $\text{Ln}^{3+}$  ions (Ln = Er, Tm, Ho) in the  $\text{Li}_2\text{ZnGeO}_4$  germanate olivines.

Initially, the near-infrared emission spectra and decays of  $\text{Li}_2\text{ZnGeO}_4:\text{Ln}^{3+}$  (Ln = Er, Tm, Ho) were tested under different excitation wavelengths. The spectra measured for the  $\text{Ln}^{3+}$ -doped samples show near-infrared luminescent bands corresponding to the characteristic electronic transitions of  $\text{Ln}^{3+}$  ions at 1550 nm (Ln = Er), 1450 nm and 1800 nm (Ln = Tm) and 2000 nm (Ln = Ho), as schematized in the energy level diagram (Fig. 4). These optical effects were not observed for the undoped  $\text{Li}_2\text{ZnGeO}_4$  sample, which is experimental proof for the presence of lanthanide ions ( $\text{Er}^{3+}$ ,  $\text{Tm}^{3+}$  or  $\text{Ho}^{3+}$ ) in the final products. Generally, it is also accepted for inorganic phosphors that each excited state of  $\text{Ln}^{3+}$  ions further splits under the influence of the crystal field produced by the chemical environment.<sup>62</sup> Thus, the broad emission bands consist of several Stark components induced by the crystal field and their spectral profiles are usually unsymmetrical. The comparative studies indicated that the infrared emission peaks originating from sub-levels of erbium ions are quite well-resolved and the Stark level structures of multiplets depending on the crystalline field of the inorganic matrices are completely different for the  $\text{Y}_2\text{O}_3:\text{Er}^{3+}$ ,  $\text{Sc}_2\text{O}_3:\text{Er}^{3+}$  and  $\text{YF}_3:\text{Er}^{3+}$  systems.<sup>63</sup> In the case of

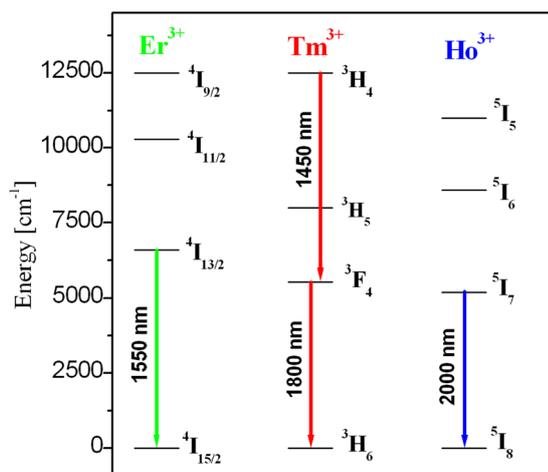

Fig. 4 Energy level diagram of  $\text{Ln}^{3+}$  ions, with near-infrared luminescence transitions indicated.

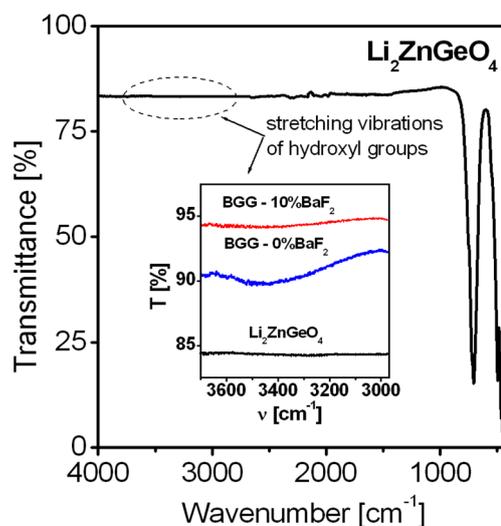

Fig. 5 Transmittance spectrum of germanate ceramics  $\text{Li}_2\text{ZnGeO}_4$ . Inset shows the transmittance bands due to the stretching vibration of  $\text{OH}^-$  groups. For comparison, the results for germanate glass (BGG) are also given.

$\text{Li}_2\text{ZnGeO}_4:\text{Ln}^{3+}$  (where Ln denotes Er, Tm or Ho), its Stark level structure of multiplets is rather less evidenced and the experimental results are comparable to the  $\text{NaLaMgWO}_6$  inorganic phosphors emitting near-infrared radiation from sub-levels of  $\text{Nd}^{3+}$  and  $\text{Er}^{3+}$  ions.<sup>64</sup>

The preliminary spectroscopic results for the  $\text{Er}^{3+}$ ,  $\text{Tm}^{3+}$  and  $\text{Ho}^{3+}$  ions in the  $\text{Li}_2\text{ZnGeO}_4$  olivines indicate that the profiles of the emission bands and decays from the excited states of  $\text{Ln}^{3+}$  are nearly independent of the excitation wavelength. This suggests that the  $\text{Ln}^{3+}$  ions occupy only one site in  $\text{Li}_2\text{ZnGeO}_4$ , in contrast to  $\text{Y}_2\text{SiO}_5$  (ref. 65) or  $\text{CaSc}_2\text{O}_4$ ,<sup>66,67</sup> where two  $\text{Er}^{3+}$  centers were identified using emission spectroscopy. At this moment, it should be noticed that the atomic positions of  $\text{Zn}^{2+}$  may be occupied by  $\text{Ln}^{3+}$ . This was observed earlier for similar germanate olivines,  $\text{Li}_2\text{SrGeO}_4:\text{RE}^{3+}$ , where the positions of the divalent  $\text{Sr}^{2+}$  were occupied by trivalent lanthanide ( $\text{Ce}^{3+}$ ,  $\text{Tb}^{3+}$ , or  $\text{Dy}^{3+}$ ) ions.<sup>68</sup>

Fig. 6 presents the near-infrared luminescence spectrum of  $\text{Li}_2\text{ZnGeO}_4:\text{Er}^{3+}$  excited at 980 nm line. The characteristic emission band at 1542 nm corresponds to the  $^4\text{I}_{13/2} \rightarrow ^4\text{I}_{15/2}$  ( $\text{Er}^{3+}$ ) transition. The excitation spectrum for  $\text{Li}_2\text{ZnGeO}_4:\text{Er}^{3+}$  measured by monitoring the emission wavelength at 1542 nm is presented in the inset of Fig. 6. The band located at 980 nm corresponds to the transition originating from the  $^4\text{I}_{15/2}$  ground state to the  $^4\text{I}_{13/2}$  excited state of  $\text{Er}^{3+}$ .

Fig. 7 shows the emission decay from the  $^4\text{I}_{13/2}$  state of  $\text{Er}^{3+}$ . Previous studies demonstrated that the emission decays from the  $^4\text{I}_{13/2}$  state of  $\text{Er}^{3+}$  in some ceramic compounds can vary greatly with experimental values ranging from microseconds to milliseconds. In fact, the  $^4\text{I}_{13/2}$  lifetime of  $\text{Er}^{3+}$  ions changed from 370  $\mu\text{s}$  for  $\text{Ca}_2\text{SiO}_4:\text{Er}^{3+}$  phosphors obtained from agro-food waste materials<sup>69</sup> to 9.5 ms for  $\text{Ba}(\text{Zr}, \text{Mg}, \text{Ta})\text{O}_3:\text{Er}^{3+}$  perovskite ceramics.<sup>70</sup> In our case, the decay curve was well fitted using a mono-exponential function given by  $I(t) = I_0 \exp(-t/\tau_m)$  and the calculated luminescence lifetime  $^4\text{I}_{13/2}$  ( $\text{Er}^{3+}$ ) in the

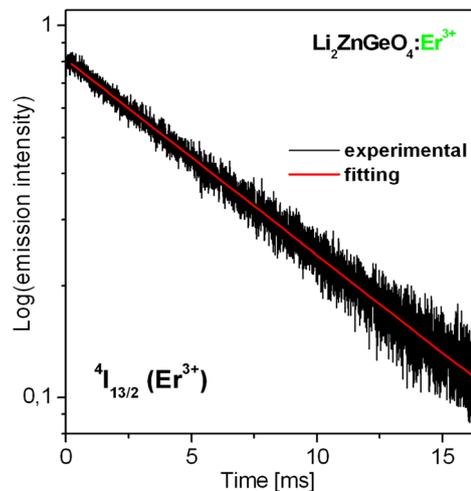

Fig. 7 Luminescence decay from the  $^4\text{I}_{13/2}$  excited state of  $\text{Er}^{3+}$  ions.

$\text{Li}_2\text{ZnGeO}_4$  germanate ceramics possessing an olivine structure is nearly 8.27 ms. The  $\text{Li}_2\text{ZnGeO}_4:\text{Er}^{3+}$  germanate ceramics exhibit a relatively large  $^4\text{I}_{13/2}$  lifetime compared to the values obtained for similar oxide phosphors documented in the literature. For example, the luminescence decay from the  $^4\text{I}_{13/2}$  state is considerably longer compared with the values for  $\text{Er}^{3+}$  ions in  $\text{ZnO}$  semiconductor quantum dots<sup>71</sup> and germanate compounds.<sup>72–74</sup>

Fig. 8 presents the near-infrared luminescence spectrum of the  $\text{Li}_2\text{ZnGeO}_4:\text{Tm}^{3+}$  germanate olivines under 797 nm excitation. The inset shows the excitation spectrum measured on monitoring the emission wavelength at 1802 nm, where the two characteristic bands are related to the  $^3\text{F}_2, ^3\text{F}_3 \rightarrow ^3\text{H}_6$  (650–700 nm) and  $^3\text{H}_4 \rightarrow ^3\text{H}_6$  (797 nm) transitions of the  $\text{Tm}^{3+}$  ions. The latter transition near 800 nm, *i.e.*  $^3\text{H}_4 \rightarrow ^3\text{H}_6$  transition, is often

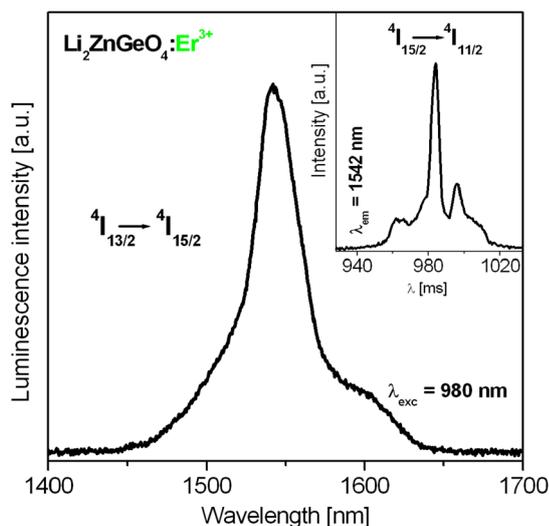

Fig. 6 Near-infrared emission spectrum of  $\text{Li}_2\text{ZnGeO}_4:\text{Er}^{3+}$ . The inset shows the excitation spectrum under monitoring the emission wavelength at 1542 nm.

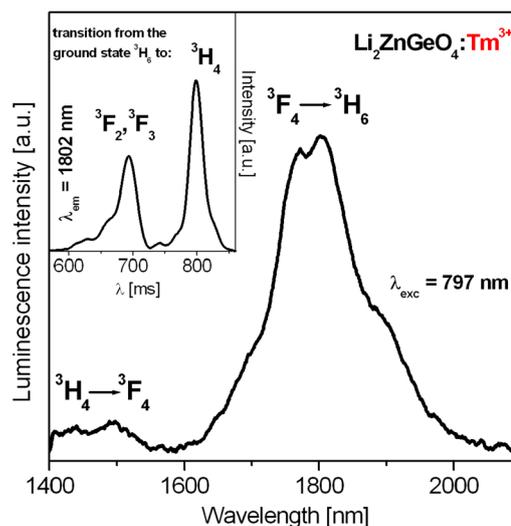

Fig. 8 Near-infrared emission spectrum of  $\text{Li}_2\text{ZnGeO}_4:\text{Tm}^{3+}$ . The inset shows the excitation spectrum under monitoring the emission wavelength at 1802 nm.

used as the excitation line to examine the up-conversion processes and near-infrared luminescence properties of thulium ions in numerous inorganic compounds.<sup>75,76</sup>

Two emission bands were observed for  $\text{Tm}^{3+}$  in the studied spectral range of 1400–2100 nm under 797 nm excitation. The near-infrared emission bands correspond to the  $^3\text{H}_4 \rightarrow ^3\text{F}_4$  and  $^3\text{F}_4 \rightarrow ^3\text{H}_6$  transitions of  $\text{Tm}^{3+}$ . The near-infrared luminescence band near 1450 nm corresponding to the  $^3\text{H}_4 \rightarrow ^3\text{F}_4$  transition of the  $\text{Tm}^{3+}$  ions was successfully quenched due to the presence of a cross-relaxation (CR) process between the  $^3\text{H}_4$  excited state and  $^3\text{H}_6$  ground state. The  $^3\text{H}_4$  state is quickly depopulated because the cross-relaxation process between pairs of  $\text{Tm}^{3+}$ :  $^3\text{H}_4 + ^3\text{H}_6 \rightarrow ^3\text{F}_4 + ^3\text{F}_4$  is very efficient.<sup>77–81</sup> Consequently, the intensity of the near-infrared emission band centered at 1802 nm due to the  $^3\text{F}_4 \rightarrow ^3\text{H}_6$  transition is significantly strong. Moreover, the emission linewidth for the  $^3\text{F}_4 \rightarrow ^3\text{H}_6$  transition of thulium in  $\text{Li}_2\text{ZnGeO}_4:\text{Tm}^{3+}$  defined as the full width at half maximum (FWHM) is relatively broad and equals 145 nm.

Fig. 9 shows the emission decays from the  $^3\text{H}_4$  and  $^3\text{F}_4$  states of thulium ions in the olivine  $\text{Li}_2\text{ZnGeO}_4:\text{Tm}^{3+}$ . In both cases, the emission decay curves become nearly mono-exponential. Based on the decays, the luminescence lifetimes for both the  $^3\text{H}_4$  and  $^3\text{F}_4$  excited states of  $\text{Tm}^{3+}$  ions were determined. The values of the emission lifetimes are close to 0.2 ms ( $^3\text{H}_4$ ) and 2.14 ms ( $^3\text{F}_4$ ), respectively. This indicates that the lifetime of  $\text{Tm}^{3+}$  (0.5 mol%) is nearly 10-fold larger for the  $^3\text{F}_4$  state than the  $^3\text{H}_4$  state. Interestingly, similar effects were also observed for  $\text{Tm}^{3+}$  ions in apatite-type germanate phosphors with the chemical formula  $\text{NaLa}_9(\text{GeO}_4)_6\text{O}_2$ , where the activator concentration-dependent decay times were larger for the  $^3\text{F}_4$  state (133–1313  $\mu\text{s}$ ) than the  $^3\text{H}_4$  state (19–432  $\mu\text{s}$ ).<sup>82</sup>

Finally, the germanate ceramics with an olivine structure doped with  $\text{Ho}^{3+}$  ions were investigated. In general,  $\text{Ho}^{3+}$ -doped germanates belonging to the family of low-phonon systems are known as efficient compounds emitting near-infrared radiation

at 2000 nm.<sup>53</sup> However, the infrared emission properties of  $\text{Ho}^{3+}$  ions in germanate ceramics have not been studied to date, to the best of our knowledge. Recently,  $\text{Ho}^{3+}:\text{Y}_2\text{O}_3\text{-MgO}$  nanocomposite ceramics have been proposed as new promising IR emitting materials for use in high-power eye-safe laser systems operating in the 2  $\mu\text{m}$  wavelength range.<sup>83</sup> Previous works published by Singh *et al.*<sup>84–86</sup> focused on green light emitting phosphors containing  $\text{Ho}^{3+}$ . Here, the results for  $\text{Li}_2\text{ZnGeO}_4:\text{Ho}^{3+}$  emitting IR radiation near 2000 nm are presented and discussed. The near-infrared emission spectrum corresponding to the  $^5\text{I}_7 \rightarrow ^5\text{I}_8$  transition of  $\text{Ho}^{3+}$  ions is presented in Fig. 10.

The emission spectrum centered at 1998 nm was measured under 450 nm excitation. The value of FWHM for the  $^5\text{I}_7 \rightarrow ^5\text{I}_8$  transition of  $\text{Ho}^{3+}$  is equal to 112 nm. The inset presents the excitation spectrum for  $\text{Li}_2\text{ZnGeO}_4:\text{Ho}^{3+}$  measured by monitoring the emission wavelength at 1998 nm. The spectrum consists of bands assigned to transitions of  $\text{Ho}^{3+}$  ions, which originate from the  $^5\text{I}_8$  ground state to the higher-lying  $^5\text{G}_{4,5}$ ,  $^5\text{G}_6$ ,  $^5\text{F}_{2,3}$  and  $^5\text{S}_2$ ,  $^5\text{F}_4$  excited states. The intensity of band centered at 450 nm due to the  $^5\text{I}_8 \rightarrow ^5\text{G}_6$  transition is considerably higher compared to other bands. Therefore, the 450 nm excitation line is often chosen to measure the near-infrared emission properties of holmium ions.<sup>87</sup> Fig. 11 shows the nearly mono-exponential luminescence decay from the  $^5\text{I}_7$  state of holmium ions in the  $\text{Li}_2\text{ZnGeO}_4:\text{Ho}^{3+}$  germanate olivine.

Based on the decay measured from the  $^5\text{I}_7$  state of holmium in  $\text{Li}_2\text{ZnGeO}_4:\text{Ho}^{3+}$ , the emission lifetime was calculated and its experimental value is close to 6.98 ms. The lifetime  $^5\text{I}_7$  ( $\text{Ho}^{3+}$ ) in the  $\text{Li}_2\text{ZnGeO}_4:\text{Ho}^{3+}$  germanate olivine is comparable with the values obtained for  $\text{Y}_3\text{Al}_5\text{O}_{12}:\text{Ho}^{3+}$  ceramics ( $\tau = 7.04$  ms) produced from laser-ablated nanoparticles<sup>88</sup> and  $\text{Yb}_3\text{Ga}_5\text{O}_{12}$  nanocrystals with 0.5%  $\text{Ho}^{3+}$  ( $\tau = 7.77$  ms) synthesized *via* the sol-gel combustion technique using citric acid.<sup>89</sup>

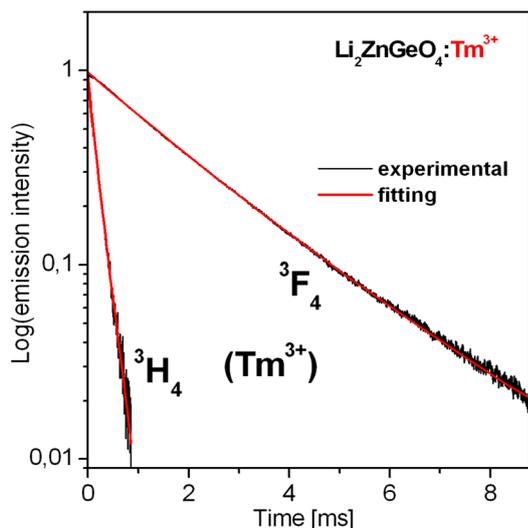

Fig. 9 Luminescence decays from the  $^3\text{H}_4$  and  $^3\text{F}_4$  excited states of  $\text{Tm}^{3+}$ .

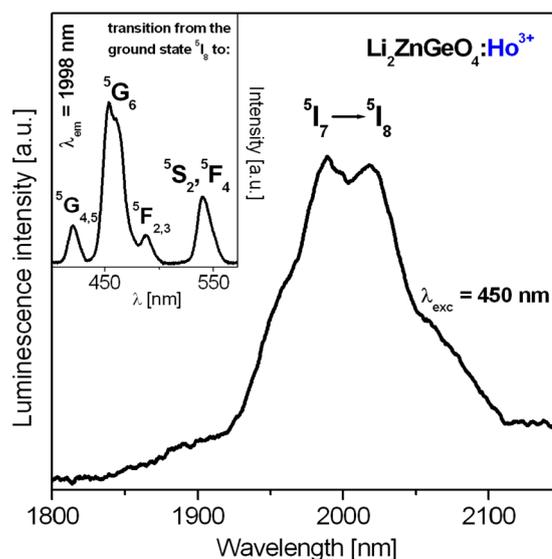

Fig. 10 Near-infrared emission spectrum of  $\text{Li}_2\text{ZnGeO}_4:\text{Ho}^{3+}$ . The inset shows the excitation spectrum under monitoring the emission wavelength at 1998 nm.

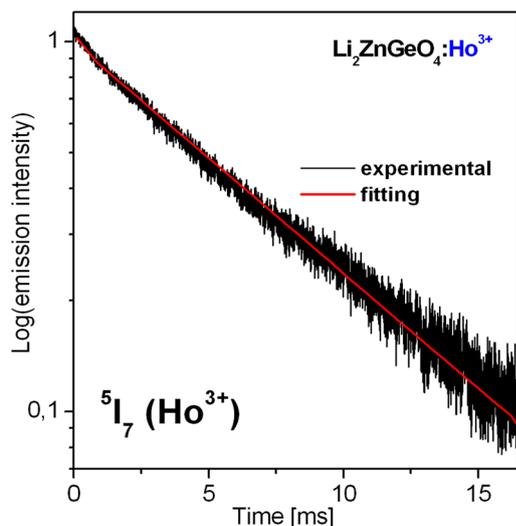

Fig. 11 Luminescence decay from the  $^5I_7$  excited state of  $\text{Ho}^{3+}$  ions.

Finally, the photoluminescence quantum yield (PLQY), which is defined as the ratio of the number of emitted photons to the number of absorbed photons, was determined by the absolute method using an integrating sphere.<sup>90</sup> Among the infrared phosphors, the determination of the absolute photoluminescence quantum yield is mainly limited to erbium-doped compounds emitting radiation near 1500 nm under 980 excitation. For example, literature data indicates that the PLQY values changed significantly from 3.6% (in water) for poly(acrylic acid) (PAA)-modified  $\text{NaLnF}_4:40\text{Gd}/20\text{Yb}/2\text{Er}$  nanorods<sup>91</sup> up to even 18.7% for  $\text{NaErF}_4@ \text{NaYbF}_4@ \text{NaYF}_4$  nanoparticles,<sup>92</sup> 32.8% for  $\text{NaCeF}_4:\text{Er}/\text{Yb}$  nanocrystals,<sup>93</sup> and 35.74% for  $\text{Ce}^{3+}/\text{Er}^{3+}:\text{LiYbF}_4$  nanocrystals.<sup>94</sup> Further luminescent studies on up-converted  $\text{PbF}_2:\text{Er}^{3+}/\text{Yb}^{3+}$  crystals fabricated using the Bridgman method well demonstrated that the PLQY values varied from 2.7% to 4.5%, depending on the activator ( $\text{Er}^{3+}/\text{Yb}^{3+}$ ) content.<sup>95</sup> In our case, the absolute quantum yield of NIR luminescence near 1550 nm (excited at 988 nm) for the  $\text{Li}_2\text{-ZnGeO}_4:\text{Er}^{3+}$  sample in the powder pellet form is close to 5.9% and its value is comparable to the experimental results (PLQY = 6%) obtained for core-shell nanostructures with homogeneous core ( $\alpha\text{-NaYF}_4:\text{Yb}^{3+}/\text{Er}^{3+}$ ) and shell ( $\alpha\text{-NaYF}_4$ ) domains.<sup>96</sup> However, the latter PLQY value increased to 30% in the case of  $\alpha\text{-NaYF}_4:\text{Yb}^{3+}/\text{Er}^{3+}$  core-shell structures with heterogeneous ( $\text{CaF}_2$ ) shell domains. A similar situation was observed for the same  $\alpha\text{-NaYF}_4:\text{Yb}^{3+}/\text{Er}^{3+}$  core-shell systems with  $\text{Ce}^{3+}$  co-doping. The structural transformation from homogeneous ( $\alpha\text{-NaYF}_4$ ) to heterogeneous ( $\text{CaF}_2$ ) shell domains strongly influenced the PLQY values determined for  $\alpha\text{-NaYF}_4:\text{Yb}^{3+}/\text{Er}^{3+}/\text{Ce}^{3+}$  core nanocrystals. Thus, the absolute quantum yield increased drastically from 24% up to 50% at  $60 \text{ mW cm}^{-2}$ ; one of the highest reported PLQY values to date.<sup>96</sup>

In summary, we can conclude that the near-infrared luminescence of lanthanides ( $\text{Er}^{3+}$ ,  $\text{Tm}^{3+}$ ,  $\text{Ho}^{3+}$ ) in the studied  $\text{Li}_2\text{-ZnGeO}_4$  olivines is quite long-lived. Our experimental studies based on near-infrared luminescence spectra and their decays

indicate that the  $\text{Li}_2\text{ZnGeO}_4:\text{Ln}^{3+}$  ( $\text{Ln} = \text{Er}$ ,  $\text{Tm}$ ,  $\text{Ho}$ ) germanate olivines are promising inorganic phosphors and can be successfully used as ceramic sources emitting near-infrared radiation.

## Conclusion

The near-infrared luminescence properties of  $\text{Li}_2\text{ZnGeO}_4:\text{Ln}^{3+}$  ( $\text{Ln} = \text{Er}$ ,  $\text{Tm}$ ,  $\text{Ho}$ ) ceramic phosphors belonging to the family of germanate olivines were investigated for the first time. Their spectra showed near-infrared emission bands centered at 1550 nm, 1450 nm, 1800 nm and 2000 nm, corresponding to  $^4I_{13/2} \rightarrow ^4I_{15/2}$  ( $\text{Er}^{3+}$ ),  $^3H_4 \rightarrow ^3F_4$  and  $^3F_4 \rightarrow ^3H_6$  ( $\text{Tm}^{3+}$ ), as well as  $^5I_7 \rightarrow ^5I_8$  ( $\text{Ho}^{3+}$ ) transitions, respectively. The decay curve analysis demonstrated that the lifetimes for the excited states of  $\text{Ln}^{3+}$  ( $\text{Ln} = \text{Er}$ ,  $\text{Tm}$ ,  $\text{Ho}$ ) are relatively long. The experimental results showed that the  $\text{Li}_2\text{ZnGeO}_4:\text{Ln}^{3+}$  germanate olivines are attractive inorganic phosphors and can be applied as ceramic sources emitting near-infrared radiation.

## Data availability

The data are available upon request from the authors.

## Author contributions

Conceptualization, project administration, resources and funding acquisition: Joanna Pisarska. Investigation and validation: Nikola Bednarska-Adam prepared the ceramic samples. Nikola Bednarska-Adam and Marta Kuwik performed spectroscopic and optical experiments. Tomasz Goryczka performed the XRD and SEM experiments. Vitalii Ivanov and Józef Dresner performed the absolute photoluminescence quantum yield test. Methodology: Joanna Pisarska and Wojciech A. Pisarski. Formal analysis and supervision: Wojciech A. Pisarski. Writing – original draft: Joanna Pisarska. Writing – review & editing: Joanna Pisarska.
