# Facile synthesis of an $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXene heterojunction for enhanced acetone gas sensors

 Zhenyuan Yang<sup>ab</sup> and Ying Chen<sup>ib</sup>\*<sup>ab</sup>

Acetone is harmful to the environment and human health. Therefore, research on acetone sensors for its high-efficiency detection is necessary. Herein, an  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXene heterojunction was synthesized using a simple precipitation method, and its sensitivity towards acetone was systematically investigated. The response value of the sensor based on the  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXene heterojunction to 50 ppm acetone was 24 at 150 °C, which was more than one-quarter of that of pure  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> (5.3). The best response and recovery time were 10 s and 6 s, respectively. The sensors also showed good stability and selectivity. The excellent gas sensitivity was mainly attributed to the formation of heterojunctions, which improved the carrier-transport efficiency and the specific surface area for gas molecular adsorption.

## Introduction

Acetone is a common volatile organic compound (VOC), which can greatly harm the human throat, liver, kidney, and nerves if inhaled in a certain amount.<sup>1</sup> It is also an important biomarker in human breath, which can be used for the preliminary review and diagnosis of diabetes.<sup>2</sup> Therefore, the development of a high-performance acetone sensor could not only allow the monitoring of air quality in real-time but would also be beneficial for human health.<sup>3</sup>

In recent years, ZnO,<sup>4</sup> WO<sub>3</sub>,<sup>5</sup> TiO<sub>2</sub>,<sup>6</sup> SnO<sub>2</sub>,<sup>7</sup> NiO,<sup>8</sup> Co<sub>3</sub>O<sub>4</sub>,<sup>9</sup>  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>,<sup>10</sup> and other metal oxide semiconductors have been developed in the field of gas sensing. Among them,  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> is an n-type semiconductor material with a band-gap of 2.2 eV, which offers the advantages of low cost, good stability, and non-toxicity, and it is harmless.<sup>11–13</sup> Although  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> exhibits good gas-sensing properties, it usually requires a higher operating temperature and gives a slower response, which limits its application in portable and low-power devices.<sup>14</sup> Various materials have been employed to blend with  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> to improve its performance.<sup>15–19</sup> Zhang *et al.* formed a heterojunction of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> and Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene, which accelerated the carrier-transport efficiency, enlarged the specific surface area with more active sites, and thus improved its H<sub>2</sub>S gas-sensing property.<sup>20</sup> Song *et al.* successfully synthesized a Fe<sub>2</sub>O<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene heterojunction *via* an *in situ* growth method. The sensor's response was 1.31 to 70 ppb *n*-butanol.<sup>21</sup> Liu *et al.* used gold nanoparticles to modify the surface of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub>

MXene composites. The sensor's response value to 1 ppm NH<sub>3</sub> reached 16.9% at room temperature.<sup>22</sup>

Herein, an  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXene heterojunction was successfully synthesized *via* a simple precipitation method. The thin sheet structure of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> was evenly distributed on the accordion-like structure of Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene, which provided more active sites for gas molecular adsorption. The formation of a heterojunction also improved the carrier-transport efficiency. The response value of the sensor based on the  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXene heterojunction to 50 ppm acetone was 24 at 150 °C with a response/recovery time of 10 s/6 s.

## Materials and methods

### Synthesis of Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene and $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene

**Chemical reagents.** Hydrofluoric acid (HF, 40%), ferrous sulfate (FeSO<sub>4</sub>·7H<sub>2</sub>O, AR), and sodium acetate (CH<sub>3</sub>COONa, AR) were purchased from Sinopharm Group Chemical Co., Ltd. Ti<sub>3</sub>AlC<sub>2</sub> (99%) was purchased from Jilin 11 Technology Co., Ltd. Deionized (DI) water was made in the laboratory.

**Synthesis of Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene.** Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene was synthesized by etching Ti<sub>3</sub>AlC<sub>2</sub> with HF. Next, 1 g of Ti<sub>3</sub>AlC<sub>2</sub> was slowly added to 20 mL of 40% HF with stirring. After stirring at 60 °C for 24 h, the obtained black solution was centrifuged and washed with deionized water. The centrifugal speed was 4000 rpm, and the time was 10 min. The mixtures were centrifuged and washed several times until the supernatant pH was 7. The precipitation was vacuum dried at 60 °C for 48 h and then triturated to obtain Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene as a multilayer black powder.

**Synthesis of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>.**  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> was synthesized by a precipitation method. First, 0.556 g of FeSO<sub>4</sub>·7H<sub>2</sub>O and 0.3 g of CH<sub>3</sub>-COONa were added to 60 mL deionized water and then stirred for 12 h at room temperature. Then the mixture was centrifuged

<sup>a</sup>School of Science, Hubei University of Technology, Wuhan 430068, China. E-mail: chenying@hbut.edu.cn

<sup>b</sup>Hubei Engineering Technology Research Center of Energy Photoelectric Device and System, Hubei University of Technology, Wuhan 430068, China

and washed several times with deionized water and ethanol. After being dried at 80 °C for 10 h, the precipitations were calcined at 600 °C for 2 h to obtain the  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> powders. The synthesis process was repeated three times under the same experimental conditions as above to conduct error analysis in the subsequent test of the gas sensor performance. Synthesis of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXene composite materials followed the same method.

**Synthesis of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXene.** A series of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXenes in different proportions were synthesized by a precipitation method. First, 0.01, 0.03, 0.05, and 0.1 g Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXenes were ultrasonically dispersed in 50 mL of deionized water, respectively. Then, to each Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene water solution was added 0.556 g of FeSO<sub>4</sub>·7H<sub>2</sub>O and 0.3 g of CH<sub>3</sub>COONa to obtain a mixture. These mixtures were continuously stirred for 12 h at room temperature. These mixtures were then centrifuged and washed several times with deionized water and ethanol. After being dried at 80 °C for 10 h, the precipitations were calcined at 600 °C for 2 h to obtain the different samples of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXene, which were named M-F-0.01, M-F-0.03, M-F-0.05, and M-F-0.1, respectively.

### Characterization

The material crystal structures were characterized by X-ray diffraction (XRD, Rigaku D/Max2550, Tokyo, Japan) with Cu K $\alpha$  radiation ( $\lambda = 1.5418$  Å). The scanning range was 5°–80°. Their morphologies were observed by field-emission scanning electron microscopy (FESEM, Hitachi SU8010, Japan) and transmission electron microscopy (TEM, FEI Tecnai F20, USA). The element contents of all the samples were analyzed using an energy-dispersive X-ray spectroscopy (EDS) unit attached to the FESEM device. The elemental chemical status and compositions were identified by X-ray photoelectron spectroscopy (XPS) with Al K $\alpha$  (1486.6 eV) excitation.

### Sensor preparation and testing

The preparation of the sensors was as follows: first, the appropriate sample powders and deionized water were mixed to form a paste. Then, the paste was brushed evenly on the Al<sub>2</sub>O<sub>3</sub> ceramic surface. After drying at 160 °C for 10 h, the Al<sub>2</sub>O<sub>3</sub> ceramic and the sensor base were welded together. Finally, the sensor was aged at 180 °C for 48 h before the test.

The gas-sensitive performance was measured by a WS-30B gas-sensitive test system (Henan Weisheng Electronic Technology Co., Ltd, China), as shown in Fig. 1(b). The test system was composed of sensor resistance  $R_S$ , load resistance  $R_L$ , and current source  $V_C$ , and the working temperature of the sensor was adjusted by changing the value of  $V_{Hr}$ . By measuring the voltage  $V_{output}$  at both ends of the load resistance, then the sensor resistance value can be obtained from formula (1).

$$R_S = \frac{(V_C - V_{output})R_L}{V_{output}} \quad (1)$$

In the test process, the measured liquid was dropped on to the evaporator with a syringe and heated to vaporize it into a gas.

Fig. 1 Schematic of the (a)  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXene preparation process and (b) gas sensor test.

The relationship between the injection volume and the concentration can be determined according to formula (2).

$$V_X = \frac{V \times C \times M}{22.4 \times d \times p} \times 10^{-9} \times \frac{273 + T_R}{273 + T_B} \quad (2)$$

where  $V_X$  is the volume of the injected liquid (mL),  $V$  is the volume of the test chamber (18 L),  $C$  is the required concentration of the gas to be measured (ppm),  $M$  is the molecular weight of the liquid (g),  $d$  is the specific gravity of the liquid ( $\text{g cm}^{-3}$ ),  $p$  is the liquid purity,  $T_R$  is room temperature (°C), and  $T_B$  is the temperature in the test chamber (°C).

The response value  $S$  can be calculated using the formula  $S = R_a/R_g$ , where  $R_a$  is the resistance value of the sensor in air and  $R_g$  is the resistance value of the sensor in the test gas.

## Results and discussion

### Structure and morphology

As shown in Fig. 2(a), the diffraction peak of Ti<sub>3</sub>AlC<sub>2</sub> matched the standard card (JCPDS: 52-0875) without impurities. Comparing the XRD pattern of Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene with Ti<sub>3</sub>AlC<sub>2</sub>, the impurity peaks were weakened, while the (002) peak for Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene was shifted from 9.45° to 8.75°. The HF etching removed the Al layer and enlarged the layer spacing. These findings prove that Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene was successfully synthesized.<sup>23</sup> The  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> in Fig. 2(b) corresponded to the standard card (JCPDS: 33-0664). In the etching process of Ti<sub>3</sub>AlC<sub>2</sub>, HF removes its Al layer, then

Fig. 2 XRD patterns of (a) Ti<sub>3</sub>AlC<sub>2</sub> and Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene, (b)  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> and M-F-0.05.

the Ti atoms in  $\text{Ti}_3\text{C}_2\text{T}_x$  are converted to  $\text{Ti}^{3+}$  under acidic conditions. These ions are then oxidized to  $\text{TiO}_2$  at  $\text{Ti}_3\text{C}_2\text{T}_x$  defects. The peaks (101), (004), (200), and (211) of M-F-0.05 were due to the oxidation of  $\text{Ti}_3\text{C}_2\text{T}_x$  MXene to  $\text{TiO}_2$  at 600 °C. The content of  $\text{Ti}_3\text{C}_2\text{T}_x$  MXene was low. So, the other peaks of M-F-0.05 were consistent with  $\alpha\text{-Fe}_2\text{O}_3$ .<sup>19</sup>

As shown in Fig. 3(a), the  $\text{Ti}_3\text{AlC}_2$  surface layers fitted closely without stratification. After being etched by HF,  $\text{Ti}_3\text{AlC}_2$  lost the middle Al layer and became an accordion-like structure for  $\text{Ti}_3\text{C}_2\text{T}_x$  MXene (Fig. 3(b)).  $\alpha\text{-Fe}_2\text{O}_3$  displayed a relatively thin sheet structure (Fig. 3(c)). When  $\alpha\text{-Fe}_2\text{O}_3$  and  $\text{Ti}_3\text{C}_2\text{T}_x$  MXene formed a complex, as shown in the M-F-0.05 SEM image of Fig. 3(d),  $\alpha\text{-Fe}_2\text{O}_3$  was evenly distributed on the surface of  $\text{Ti}_3\text{C}_2\text{T}_x$  MXene. The EDS element mapping images of M-F-0.05 are shown in Fig. 3(f). The Ti, O, Fe, and C elements were evenly distributed in the composite material, which indicated that the  $\alpha\text{-Fe}_2\text{O}_3\text{-TiO}_2\text{-MXene}$  composite material had been successfully synthesized.

TEM and HRTEM images of M-F-0.05 were obtained. In Fig. 4(e), the observed lattice spacing of 0.246 nm corresponded to the (021) crystal surface of  $\text{TiO}_2$ , as shown by red dotted rectangles (Fig. 4(b) and (c)). In Fig. 4(f), the lattice spacing of 0.354 nm corresponded to the (012) crystal surface of  $\alpha\text{-Fe}_2\text{O}_3$ , as shown by the yellow dotted rectangles (Fig. 4(b) and (c)). In Fig. 4(g), the lattice spacing of 0.249 nm corresponded to the (102) crystal surface of  $\text{Ti}_3\text{C}_2\text{T}_x$  MXene, as shown by the white dotted rectangles (Fig. 4(b) and (d)).<sup>19,22</sup> These results were consistent with the XRD results.

The XPS high-resolution spectra of  $\alpha\text{-Fe}_2\text{O}_3$  are shown in Fig. 5(a) and (b). Fig. 5(a) is the Fe 2p high-resolution spectra of  $\alpha\text{-Fe}_2\text{O}_3$ . The peaks at binding energies of 723.9 and 710.2 eV

Fig. 4 (a) and (b) TEM characterization of M-F-0.05, (c)–(g) HRTEM characterization of M-F-0.05.

were attributed to Fe 2p<sub>1/2</sub> and Fe 2p<sub>3/2</sub>, respectively. The satellite peaks centered around 725.3 and 718.2 eV were from Fe<sup>3+</sup>, indicating the successful synthesis of  $\alpha\text{-Fe}_2\text{O}_3$ .<sup>24</sup> Fig. 5(b) presents the O 1s spectrum, which was mainly divided into three peaks, with peaks at binding energies of 531.7, 530.6, and 529.1 eV, corresponding to H–O–H, Fe–OH, and Fe–O bonds, respectively.<sup>25</sup>

The XPS high-resolution spectra of the M-F-0.05 heterojunction are shown in Fig. 5(c)–(f). Fig. 5(c) shows the high-resolution spectrum of Fe 2p of M-F-0.05. The peaks at

Fig. 3 SEM characterization of (a)  $\text{Ti}_3\text{AlC}_2$ , (b)  $\text{Ti}_3\text{C}_2\text{T}_x$  MXene, (c)  $\alpha\text{-Fe}_2\text{O}_3$ , (d) and (e) M-F-0.05. (f) EDS mapping for Ti, O, Fe, and C of M-F-0.05.

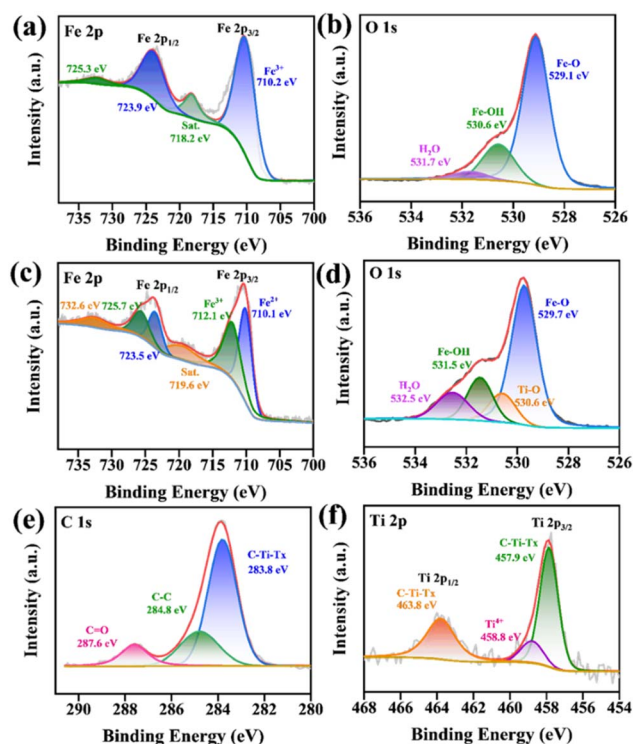

Fig. 5 XPS spectra of  $\alpha\text{-Fe}_2\text{O}_3$  (a) Fe 2p and (b) O 1s. XPS spectra of M-F-0.05 heterojunction: (c) Fe 2p, (d) O 1s, (e) C 1s, and (f) Ti 2p.

binding energies of 723.9 and 710.4 eV corresponded to Fe 2p<sub>1/2</sub> and Fe 2p<sub>3/2</sub>, respectively, while those at 710.1 and 723.5 eV were attributed to Fe<sup>2+</sup>, at 712.1 and 725.7 eV to Fe<sup>3+</sup>, and 719.6 and 732.6 eV to the satellite peaks of Fe<sup>3+</sup>.<sup>26</sup> Fig. 5(d) is the high-resolution O 1s spectrum of M-F-0.05 heterojunction. The peaks at binding energies of 532.5, 531.5, 530.6, and 529.7 eV corresponded to H–O–H, Fe–OH, Ti–O, and Fe–O bonds, respectively.<sup>27,28</sup> Fig. 5(e) shows the C 1s high-resolution spectrum of M-F-0.05. The peaks at binding energies of 287.6, 284.8, and 283.8 eV were attributed to C=O, C–C, and C–Ti–T<sub>x</sub>, respectively.<sup>29</sup> Fig. 5(f) shows the Ti 2p high-resolution spectrum of M-F-0.05, which could be divided into Ti 2p<sub>3/2</sub> (457.9 eV) and Ti 2p<sub>1/2</sub> (463.8 eV). The peaks at binding energies of 463.8, 458.8, and 457.9 eV were attributed to C–Ti–T<sub>x</sub>, Ti<sup>4+</sup>, and C–Ti–T<sub>x</sub> bonds, respectively.<sup>30</sup> The presence of Ti<sup>4+</sup> indicated that TiO<sub>2</sub> was generated in the hydrothermal process, which was consistent with the results of the XRD analysis above.

### Gas-sensitive performance

The operating temperature has a huge impact on the sensor. The lower the temperature, the fewer electrons/holes and the slower the migration rate in the gas-sensitive materials, and the response value is then low or there is even no response. Higher temperature excites more electrons and leads to a faster migration rate of electrons and holes, and so the activity of gas-sensitive materials is increased, and the response value increases accordingly. Too high an operating temperature will accelerate desorption of the gas, which is equivalent to reducing the gas adsorbed on the surface of the material, and the response value will then be reduced. Therefore, we first explored the relationship between the operating temperatures and the gas-sensing performance.<sup>31,32</sup> The gas-response values of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>, M-F-0.01, M-F-0.03, M-F-0.05, and M-F-0.1 to 50 ppm acetone at different temperatures (50 °C, 80 °C, 100 °C, 150 °C, 200 °C, and 250 °C) are shown in Fig. 6(a). The best working temperature of the sensor was 150 °C. Moreover, with the increase in Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene content,  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXene had more heterojunctions. The sensors based on M-F-0.05 showed the maximum response values at each temperature. However, the sensor based on M-F-0.1 had the smaller response values. This was possibly because excessive Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene addition

will lead to a stacking of the sheets, which reduces the adsorption sites and affects the gas-sensitive response of the composite.<sup>33</sup> Each group of experiments above tested three groups of gas sensors under the same experimental conditions, and the mean value and standard deviation were taken, and then the error bar was obtained, which represents the label difference, while the length of the error bar also represents the degree of data dispersion. The same was true for the subsequent gas-sensitivity tests. Fig. 6(b) presents the dynamic response curve of the sample to different concentrations of acetone gas at 150 °C. The response value increased with the increasing acetone concentration. The response of M-F-0.05 to 50 ppm acetone was 24, while that of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> was 5.3.

The response/recovery curves of different samples to different concentrations of acetone gas at 150 °C are shown in Fig. 7(a)–(e). Under the same test conditions, sensor M-F-0.05 had the shortest response/recovery time and the largest response value (10 s/6 s). Repeatability testing of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> and M-F-0.05 in 50 ppm acetone gas at 150 °C was carried out (Fig. 7(f)). The results showed they all had good repeatability.

Selectivity is also one of the main properties of gas sensors. The sensors were tested with 50 ppm of different gases (acetone, ethanol, ammonia, *n*-butanol, ethylene glycol, and isopropyl alcohol) at 150 °C, and the results are shown in Fig. 8(a). M-F-0.05 had the better response to acetone gas compared to the other gases. From the stability tests of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> and M-F-0.05 in 50 ppm acetone gas at 150 °C for 30 days, as shown in Fig. 8(b), M-F-0.05 also demonstrated good stability. Table 1 shows

Fig. 6 (a) Response values of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>, M-F-0.01, M-F-0.03, M-F-0.05, and M-F-0.1 to 50 ppm acetone at different temperatures. The error bar is from the mean values and standard deviations of three tested groups of gas sensors under the same experimental conditions. (b) Dynamic response values to different concentrations of acetone at 150 °C.

Fig. 7 (a)–(e)  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>, M-F-0.01, M-F-0.03, M-F-0.05, and M-F-0.1 response/recovery curves to 50 ppm acetone at 150 °C. (f) Repeatability testing of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> and M-F-0.05 in 50 ppm acetone gas at 150 °C.

Fig. 8 (a) M-F-0.05 selectivity to 50 ppm of different gases at 150 °C. (b) 30 days stability test of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> and M-F-0.05 in 50 ppm acetone gas at 150 °C. a comparison of the acetone responses between the M-F-0.05 sensor and some relevant reports. The sensor based on M-F-0.05 exhibited a relatively higher acetone response with a lower working temperature, confirming our sensor is a promising candidate for acetone detection with low power consumption.

### Gas-sensing mechanism

The gas-sensitive response of the sensing material is affected by the chemical adsorption of oxygen on the semiconductor surface and the chemical reaction of the gas molecules to be measured.<sup>42</sup> The  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXene gas sensor showed n-type semiconductor characteristics when testing acetone. Here, the oxygen in the air will be adsorbed on its surface, trapping the electrons in its conduction band to generate chemisorbed oxygen (O<sub>2</sub><sup>-</sup>), resulting in a widening of the electron depletion layer and increase in the resistance value of the material.<sup>43,44</sup> Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene with metallic properties has a work function of 4.37 eV. TiO<sub>2</sub> has a work function of 4.6 eV. After contacting, the electrons in the Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene conduction band will be transferred to the TiO<sub>2</sub> conduction band until their Fermi levels reach equilibrium. A Schottky barrier will form at the interface between Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene and TiO<sub>2</sub>. The work function of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> is 5.9 eV, therefore when it contacts with Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene-TiO<sub>2</sub> heterojunction, electrons will be transferred from the Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub>

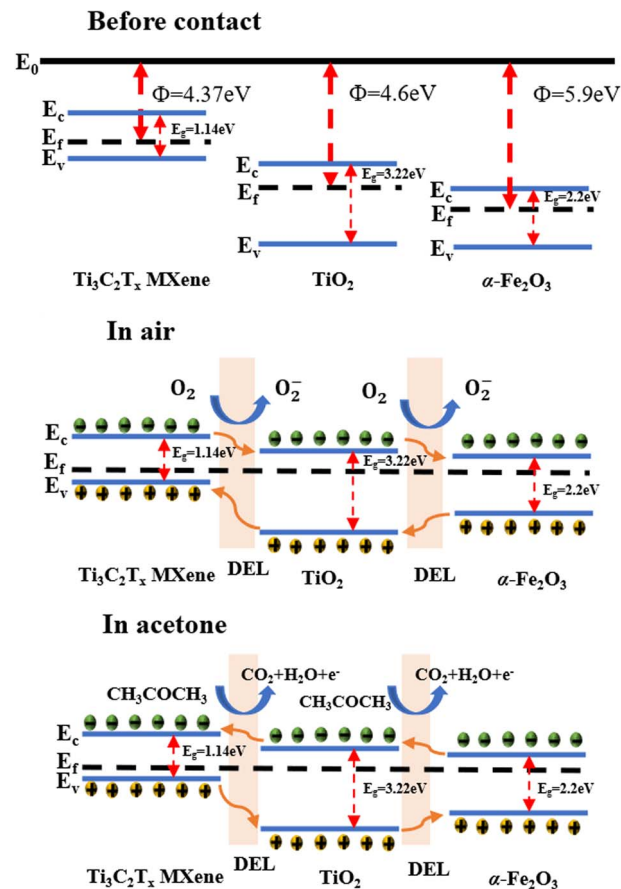

Fig. 9 Schematic of the gas-sensing mechanism of the  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXene heterojunction-based sensor.

MXene-TiO<sub>2</sub> heterojunction to  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>, and then another heterojunction will form between the Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene-TiO<sub>2</sub> heterojunction and  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>. In acetone, acetone molecules are oxidized by oxygen ions (O<sup>-</sup>) and release electrons into the conduction band of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXene, causing the electron depletion layer to narrow, thus further reducing the resistance value of the material, which plays a crucial role in improving the gas-sensitive performance. The whole reaction process is shown

in eqn (3)–(6).<sup>21,45</sup> The reaction mechanism diagram is shown in Fig. 9.

## Conclusions

$\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXene heterojunctions were successfully prepared by a simple precipitation method. The gas sensor based on them showed good responses value for 24 to 50 ppm acetone at 150 °C, which was more than a-quarter that of pure  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> (5.3). It also had a shorter response/recovery time (10 s/6 s) and a better stability. The enhanced gas sensitivity of the  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXene gas sensor may be mainly due to two reasons. (1) The  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXene heterojunction could improve the electron-transfer efficiency. (2) The  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>-TiO<sub>2</sub>-MXene heterojunction has a larger specific surface area with more active sites for gas-sensitive reactions. This article provides an idea for developing excellent acetone sensor-sensitive materials. However, the optimal working temperature needs to be further reduced.
