# Enantioselective synthesis of spiro[indoline-3,1'-pyrazolo[1,2-*b*]phthalazine] derivatives *via* an organocatalytic three-component cascade reaction†

 Luying Song,<sup>‡ab</sup> Yuhong Sun,<sup>‡ab</sup> Renbo An,<sup>b</sup> Liming Wang<sup>\*a</sup> and Ying Jin<sup>ID \*ab</sup>

An asymmetric synthesis of spiro[indoline-3,1'-pyrazolo[1,2-*b*]phthalazine] derivatives was first developed through an organocatalysed cascade Knoevenagel/Michael/cyclization reaction using a quinidine-derived squaramide. Under the optimized conditions, the three-component reaction of isatins, malononitrile (cyanoacetate) and phthalhydrazide yields the desired pyrazolophthalazinyli spirooxindoles in good yields (73–90%) with up to >99% enantiomer excess (ee).

## Introduction

The pyrazole ring is a key moiety in numerous biologically active compounds and clinical drugs,<sup>1</sup> such as Viagra, Celebrex, and Analginum (Fig. 1). Therefore, the synthesis of heterocyclic compounds containing the pyrazole ring is a research hotspot in the fields of organic synthesis and medicinal chemistry.

On the other hand, heterocyclic fused phthalazines have been found to possess cytotoxic, antimicrobial, anticonvulsant, antifungal, anticancer, anti-inflammatory, and cardiogenic activities.<sup>2</sup> They also exhibited potential as new luminescence materials or fluorescence probes.<sup>3</sup>

In addition, optically active spirooxindole derivatives have been extensively investigated because of their prominent activities and wide utility as synthetic intermediates for alkaloids and clinical drugs.<sup>4</sup> The methods for synthesizing various spirooxindoles, including spiro[N-heterocycle-oxindoles], spiro[cycloalkane-oxindoles] and spiro[O-heterocycle-oxindoles] *etc.*

have been well established.<sup>5a</sup> Over the past few years, significant progress has been made in the stereoselective construction of spirooxindole.<sup>5</sup>

Based on the biological activity of pyrazole, phthalazine, and spiroindole skeleton, according to the splicing principle, chemists have considered combining these three parts into one molecule. At present, several methods have been developed for the synthesis of racemic spiro[indoline-3,1'-pyrazolo[1,2-*b*]phthalazine] derivatives.<sup>6</sup> Zhang,<sup>6a</sup> Shi<sup>6b</sup> and Kefayati<sup>6c</sup> groups reported one-pot three-component reaction catalyzed by nickel chloride, pyridine, or tetrabutylammonium fluoride (TBAF) respectively as shown in Scheme 1(a). However, there are no reports on the synthesis of optically pure pyrazolophthalazinyli spirooxindoles.

As well known, the development of synthetic methods to access optically active spiro-heterocycles would be of significance for drug discovery.<sup>7</sup> So, we herein first reported the asymmetric Michael/cyclization cascade reaction of malononitrile (cyanoacetate), phthalhydrazide with a variety of the substituted isatins (N1, C4, C5, C6, C7 substituents) to construct spiro-heterocycles by using cinchona-squaramide catalyst

Scheme 1 Spiro[indoline-3,1'-pyrazolo[1,2-*b*]phthalazine].

Fig. 2 The structure of catalysts **1a–1i**.

(Scheme 1(b)). Bifunctional organocatalysts **1a–1i** including cinchona alkaloids and Takemoto's catalysts bearing (thio)urea or squaramide<sup>8</sup> have been applied in this cascade reaction as shown in Fig. 2.

## Results and discussion

We initially screened the bifunctional catalysts in the Knoevenagel/Michael/cyclization reaction of isatin (**2a**), malononitrile (**3a**) and phthalhydrazide with DCM as a solvent in the presence of 10 mol% of catalysts **1a–1i** (Table 1).

As shown in Table 1, catalysts **1a–i** smoothly catalyzed the reaction to provide the desired product in 75–88% yields (entries 1–9). Among them, quinidine-derived squaramide catalyst **1c** was screened to be the optimal catalyst in terms of yield and enantioselectivity (98% ee, entry 3). In addition, Takemoto's catalyst **1f** with a urea moiety and catalyst **1i** bearing a squaramide moiety induced the reaction with excellent enantioselectivities (entries 6 and 9). By comparison, catalysts **1e** and **1h** with a thiourea moiety showed bad asymmetric induction to give decreased ee values (79% and 89%, entries 5 and 8).

Since stereoselectivity of up to 98% has been achieved under the current conditions, there is not much room for further improvement. However, we would like to investigate the effect of solvents on the stereoselectivity of the reaction, and whether lowering the loading of catalyst can maintain excellent enantioselectivity. The results showed that solvents have a significant impact on the catalytic performance of the catalyst. Among the 8 selected solvents, dichloromethane was screened as the optimal solvent for the yield and enantioselectivity (entry 3), and halogenated alkane as solvents were found to be suitable for this reaction to give 93% and 95% ees respectively (entries 10 and 11), while low enantioselectivities were obtained in ethyl acetate and EtOH (entries 13 and 14). Surprisingly, Et<sub>2</sub>O was used as solvent, the transformation did not occur even with prolonged the reaction time of 36 h (entry 15). Additionally, reducing the catalyst loading to 5 mol% led to an obvious decrease in enantioselectivity and yield (entry 16 vs. 3). Thus,

<sup>a</sup> Reaction conditions: isatin **2a** (0.1 mmol), malononitrile **3a** (0.1 mmol), phthalhydrazide (0.1 mmol) and catalysts **1a–1i** in solvent (1.0 mL) at rt for 24 h. <sup>b</sup> Isolated yield. <sup>c</sup> Determined by HPLC analysis (Chiralpak OJ-H). <sup>d</sup> The sign in parentheses indicates the sign of the optical rotation.

the optimized conditions were determined to be DCM as the solvent with a 10 mol% loading of catalyst **1c** at rt.

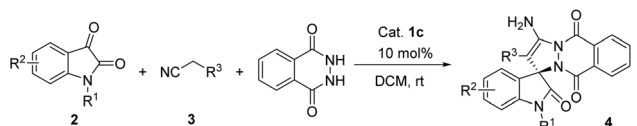

With the optimized conditions in hand, we explored the scope and general applicability of the protocol. A wide range of substituted isatins (N1, C4, C5, C6 and C7 substituents) and 2 types of electron-rich nucleophiles, including malononitrile and cyanoacetates, were evaluated as shown in Table 2.

All of the substrates reacted smoothly to give the corresponding products in 73–90% yield with excellent ees (88–>99%). Compared with *N*1-benzyl substituted isatin, no substitution or methyl substituted isatin as substrates were found to be better for the enantioselectivity (entries 1 and 16 vs. entry 17). To broaden the scope of substrates, cyanoacetates were applied instead of malononitrile in the reaction, and excellent ee values of 91–99% were obtained (entries 19–23). Notably, ethyl cyanoacetate as substrate was found to be better than methyl cyanoacetate for the enantioselectivity and yield of the reaction (entry 20 vs. entry 19). Therefore, the screened catalytic condition showed excellent general applicability for this three components cascade reaction.

The absolute configuration of spiro[indoline-3,10-pyrazolo[1,2-*b*]phthalazine] products **4** were unambiguously assigned as *S* according to the X-ray crystal structure analysis of **4d** (Fig. 3).

On the basis of the absolute stereochemistry of **4d**, a plausible mechanism for the formation of spirooxindole derivative **4d** was proposed according to the literature (Scheme 2).<sup>10</sup> Isatin (**2a**) first condenses with malononitrile to yield the isatylidene

malononitrile (**A**), one cyanide group of which is fixed and activated by the neighboring two squaramide N–H moieties through double H-bonding, while phthalhydrazide is activated by an interaction between the tertiary amine moiety of **1c** and the amino group of phthalhydrazide (**B**). Then, *Si*-face addition of the nucleophilic phthalhydrazide to the electron-deficient isatylidene malononitrile results in a Michael adduct intermediate (**C**), which in turn transfers to intermediate (**D**) through proton immigration. Next, the intramolecular nucleophilic addition of the amino group to the cyano group produces a cyclic imino carbanion (**E**), which is further transformed to the

**Scheme 2** Proposed mechanism for the formation of *S*-**4d**.

final (*S*)-**4d** through subsequent proton immigration and tautomerization (Scheme 2).

## Conclusions

In summary, we described the first enantioselective Knoevenagel/Michael/cyclization cascade reaction of isatins, malononitrile (or cyanoacetates) and phthalhydrazide to produce spiro[indoline-3,10-pyrazolo[1,2-*b*]phthalazine] in high enantioselectivity (88–>99% ees). Moreover, we used our optimized conditions to expand upon the substrate scope of this reaction.
