# Synthesis of $\text{Li}_7\text{P}_3\text{S}_{11}$ solid electrolyte in ethyl propionate medium for all-solid-state Li-ion battery

Tran Anh Tu<sup>abc</sup> and Nguyen Huu Huy Phuc<sup>id</sup>\*<sup>abc</sup>

In this study, we report a facile wet chemical synthesis method for preparing  $\text{Li}_7\text{P}_3\text{S}_{11}$  solid-state electrolyte using ethyl propionate as the solvent. The structures of the samples were investigated using X-ray diffraction, Raman spectroscopy, and  $^{31}\text{P}$  nuclear magnetic resonance. The electrochemical properties of the samples were evaluated using cyclic voltammetry, direct current, and alternating-current electrochemical impedance measurements. The  $\text{Li}_7\text{P}_3\text{S}_{11}$  solid electrolyte (SE) exhibited a  $\text{Li}^+$  conductivity of  $1.5 \times 10^{-3} \text{ S cm}^{-1}$  at 25 °C. The electrochemical measurements confirmed that the synthesized electrolyte is a single  $\text{Li}^+$  conductor with stability up to 5.0 V vs.  $\text{Li}^+/\text{Li}$ . Furthermore, a solid-state battery (SSB) cell incorporating  $\text{LiNi}_{1/3}\text{Mn}_{1/3}\text{Co}_{1/3}\text{O}_2$  and the synthesized  $\text{Li}_7\text{P}_3\text{S}_{11}$  maintained stability for up to 50 cycles, demonstrating the durability of  $\text{Li}_7\text{P}_3\text{S}_{11}$  in high-voltage SSB applications. These results indicate that  $\text{Li}_7\text{P}_3\text{S}_{11}$  SE is a promising candidate for rechargeable solid-state Li-ion batteries.

## 1. Introduction

Solid-state batteries (SSBs) are a class of batteries that use solid electrolytes (SEs) instead of the liquid or gel electrolytes employed in conventional lithium-ion batteries.<sup>1</sup> SSBs offer significant advantages over conventional batteries, including higher energy density and improved safety, making them a promising technology for future energy storage, particularly in electric vehicles. SSBs can store more energy within the same volume or weight than conventional batteries, enabling longer ranges for electric vehicles.<sup>2</sup> The use of SEs, which are more stable and less prone to leakage or fire than liquid electrolytes, significantly improves safety.

Sulfide solid electrolytes are considered as promising materials for SSBs because of their high ionic conductivity, mechanical flexibility, and high energy density.<sup>3,4</sup> Among them,  $\text{Li}_7\text{P}_3\text{S}_{11}$  SE has been extensively studied for its ionic conductivity ranging from  $10^{-4}$  to  $10^{-2} \text{ S cm}^{-1}$  at room temperature.<sup>5</sup>  $\text{Li}_7\text{P}_3\text{S}_{11}$  synthesized *via* solid-state reactions has achieved a maximum ionic conductivity of  $1.7 \times 10^{-2} \text{ S cm}^{-1}$  at room temperature.<sup>6</sup> However, solid-state reactions are energy-intensive, which limits their scalability for mass production. In contrast, liquid-phase synthesis offers a more versatile

approach for the scalable production and preparation of electrode composite materials for all SSBs.<sup>7</sup>

Liquid-phase synthesis of  $\text{Li}_7\text{P}_3\text{S}_{11}$  has recently been reported, leveraging its compatibility with composite electrode preparation.<sup>8,9</sup> Among the solvents used in  $\text{Li}_7\text{P}_3\text{S}_{11}$ , acetonitrile (ACN) is the most widely used, as it enables SEs with ionic conductivity up to  $9.7 \times 10^{-4} \text{ S cm}^{-1}$  at 25 °C.<sup>10</sup> In CAN,  $\text{Li}_2\text{S}$  reacts with  $\text{P}_2\text{S}_5$  to form  $\text{Li}_3\text{PS}_4$  and  $\text{Li}_4\text{P}_2\text{S}_7$  precipitates in a 1 : 1 molar ratio.<sup>11</sup> After solvent removal, the residues  $\text{Li}_4\text{P}_2\text{S}_7 \cdot \text{ACN}$  and  $\text{Li}_3\text{PS}_4 \cdot \text{CAN}$ , yielded  $\text{Li}_7\text{P}_3\text{S}_{11}$  upon heat treatment at elevated temperatures as ACN was removed. Recently, ethyl acetate (EA) was used to synthesize  $\text{Li}_7\text{P}_3\text{S}_{11}$ , yielding an ionic conductivity of  $1.05 \times 10^{-3} \text{ S cm}^{-1}$  at 25 °C.<sup>12</sup> Unlike in CAN,  $\text{Li}_2\text{S}$  and  $\text{P}_2\text{S}_5$  completely dissolved in EA to form  $\text{Li}_7\text{P}_3\text{S}_{11}$ . Other solvents, such as 1,2-dimethoxyethane and tetrahydropyran, have also been used for the synthesis of  $\text{Li}_7\text{P}_3\text{S}_{11}$  SE.<sup>13,14</sup> Ethyl propionate (EP) has previously been used to synthesize  $\beta\text{-Li}_3\text{PS}_4$ ,  $\text{Li}_7\text{P}_2\text{S}_8\text{I}$ , and  $\text{Li}_3\text{PO}_4$ -doped  $\text{Li}_3\text{PS}_4$ , but not  $\text{Li}_7\text{P}_3\text{S}_{11}$ .<sup>15–18</sup>

In this study,  $\text{Li}_7\text{P}_3\text{S}_{11}$  SE was synthesized using EP to facilitate the reaction between  $\text{Li}_2\text{S}$  and  $\text{P}_2\text{S}_5$ .  $\text{Li}_2\text{S}$  and  $\text{P}_2\text{S}_5$  (70 : 30 molar ratio) did not fully dissolve in EP, resulting in the formation of a white precipitate and a yellowish solution. After solvent removal, the residue was heated at 250 °C for 1 h to yield  $\text{Li}_7\text{P}_3\text{S}_{11}$  SE. The prepared  $\text{Li}_7\text{P}_3\text{S}_{11}$  SE exhibited an ionic conductivity of  $1.5 \times 10^{-3} \text{ S cm}^{-1}$  at 25 °C, comparable to previously reported values. A solid-state half-cell using  $\text{Li}_3\text{InCl}_6$ -coated  $\text{LiNi}_{1/3}\text{Mn}_{1/3}\text{Co}_{1/3}\text{O}_2$  as the active material and  $\text{Li}_7\text{P}_3\text{S}_{11}$  demonstrated stable cycling performance, indicating the compatibility of the synthesized  $\text{Li}_7\text{P}_3\text{S}_{11}$  SE with high-voltage materials.

## 2. Experimental

### 2.1 Chemicals

$\text{Li}_2\text{S}$  (99.9%, Macklin),  $\text{P}_2\text{S}_5$  (99%, Macklin),  $\text{LiCl}$  (99.9%, Macklin),  $\text{InCl}_3$  (99.99%, Macklin), and super-dehydrated EP (Aldrich) were used as received without further treatment.

### 2.2 Liquid-phase synthesis of $\text{Li}_7\text{P}_3\text{S}_{11}$

A mixture of 2.0 g of  $\text{Li}_2\text{S}$  and  $\text{P}_2\text{S}_5$  (7 : 3 molar ratio) was weighed and placed in a three-necked flask with 40 ml of EP. The mixture was stirred at 300 rpm and 50 °C for 24 h, yielding a suspension containing a white precipitate and a yellowish solution (Fig. S1). The solvent was evaporated from the suspension under reduced pressure at room temperature to obtain a residue (S-RT). The residue was then ground using an agate mortar and heat-treated in an Ar atmosphere for 1 h at 190 °C (S-190), followed by 1 h at 230 °C, 240 °C and 250 °C to obtain  $\text{Li}_7\text{P}_3\text{S}_{11}$  SE (denoted as S-230, S-240, and S-250, respectively).

### 2.3 $\text{Li}_3\text{InCl}_6$ -modified $\text{LiNi}_{1/3}\text{Mn}_{1/3}\text{Co}_{1/3}\text{O}_2$ preparation

$\text{Li}_3\text{InCl}_6$ -modified  $\text{LiNi}_{1/3}\text{Mn}_{1/3}\text{Co}_{1/3}\text{O}_2$  (NMC111, MTI) containing 2 wt%  $\text{Li}_3\text{InCl}_6$  was prepared following a reported procedure.<sup>19</sup>  $\text{Li}_3\text{InCl}_6$  was synthesized according to a previously reported method.<sup>20</sup>  $\text{Li}_3\text{InCl}_6$  was dissolved in anhydrous ethanol to form a uniformly transparent solution, into which NCM111 powder was added. After solvent evaporation at 80 °C, the precursor powder was further sintered at 400 °C under a nitrogen atmosphere to yield the composite powder (LIC@NCM111).

### 2.4 Structural characterization

The structure and morphology of the prepared samples were characterized using thermogravimetry-differential thermal analysis (TG-DTA, EVO II, Rigaku), X-ray diffraction (XRD, X8, Bruker), Raman spectroscopy (Horiba LabRam HR spectrometer, 532 nm), solid-state  $^{31}\text{P}$  nuclear magnetic resonance ( $^{31}\text{P}$  NMR, Avance III 400, Bruker), scanning electron microscopy (SEM, S4800, Hitachi), and energy-dispersive X-ray spectroscopy (EDS, ULTIM MAX, Oxford Instrument).

The samples were prepared in an Ar-filled glove box and loaded into an airtight sample holder for characterization.

### 2.5 Electrochemical measurements

The electrical conductivity of a pellet prepared by uniaxially cold-pressing ~200 mg of powder at 510 MPa was measured. Alternating-current impedance spectroscopy was performed using a potentiostat (PGSTAT302N, Autolab, Herisau, Switzerland) over a frequency range of 10 MHz–10 Hz.

DC conductivities were measured using blocking and non-blocking electrodes, in which stainless-steel rods and Li metal sheets were employed as the electrodes, respectively. The pelletized sample was prepared by cold-pressing S-250 powder at 510 MPa. For nonblocking electrodes, the Li metal sheets (~8 mm diameter, 0.1 mm thickness) were attached to both faces of the pellet at room temperature. A 0.5 V DC was applied

to the cells, and the current was measured using a potentiostat (SI 1287, Solatron) to determine the dominant mobile ions.

The electrochemical compatibility was tested using a  $\text{Li}|\text{SE}|\text{Au}$  cell (Au sputtered on a stainless-steel rod) at a scan rate of 5  $\text{mV s}^{-1}$  between 0.5 and 5 V with a potentiostat (SI 1287, Solatron).

The SSB half-cell was fabricated using the following process. The cathode composite was prepared by manually mixing LIC@NCM111 and S-250 in a 70 : 30 weight ratio using an agate mortar. A bilayer pellet (10 mm diameter) consisting of the electrode composite (12 mg) and S-250 (100 mg) was obtained by cold-pressing at 310 MPa. Indium (99.99%, Macklin) and Li foil were attached to opposite sides of the SE. The cell was assembled by sandwiching the pellet between stainless-steel rods and cycled in the constant-current mode at 0.1C between 3.70 and 2.40 V vs. Li-In.

## 3. Results and discussion

Fig. 1a shows the TG-DTA curves of the S-RT. The TG curve shows two distinct stages of the mass loss process: Stage 1 occurs from approximately 50 °C to 160 °C, and Stage 2 from 270 °C to 290 °C. The DTA curve displays several endothermic peaks between 30 °C and 150 °C, along with two exothermic peaks in the ranges of 150–200 °C and 270–290 °C. The mass loss in Stage 1 is attributed to the removal of crystallized solvent molecules. The  $\text{P}_2\text{S}_7^{4-}$  group in  $\text{Li}_7\text{P}_3\text{S}_{11}$  is known to decompose at elevated temperatures, forming sulfur and  $\text{P}_2\text{S}_6^{4-}$ .<sup>21</sup> Therefore, the exothermic peak and accompanying mass loss in Stage 2 (270–290 °C) are ascribed to the decomposition of the  $\text{P}_2\text{S}_7^{4-}$  group in the sample. Fig. 1b shows the first-order derivatives of the TG and DTA curves. The first-order differential curves of TG-DTA show that the EP solvent removal process finishes at ~170 °C. The  $d(\text{DTA})$  curve illustrates an endothermic phenomenon between 230 °C and 250 °C without any mass loss, indicating the formation of  $\text{Li}_7\text{P}_3\text{S}_{11}$ . Notably, another endothermic phenomenon started at ~250 °C, accompanied by mass loss, corresponding to the decomposition of  $\text{P}_2\text{S}_7^{4-}$  ions to  $\text{P}_2\text{S}_6^{4-}$ . Based on these TG-DTA results, the experimental samples obtained after removal of the EP solvent at room temperature were heated at 190 °C for 1 h, followed by heat treatments at 230 °C, 240 °C, and 250 °C for 1 h to examine the formation of  $\text{Li}_7\text{P}_3\text{S}_{11}$ .

Fig. S2 shows the XRD patterns of the precipitate obtained after decanting the yellow supernatant (Fig. S1), along with  $\text{Li}_2\text{S}$  for comparison. The precipitate pattern shows no residual  $\text{Li}_2\text{S}$ , indicating complete consumption of  $\text{Li}_2\text{S}$  in the reaction with  $\text{P}_2\text{S}_5$  in the EP medium under specific conditions. Notably, the precipitate pattern resembled that of the  $\text{Li}_3\text{PS}_4$  precursor synthesized from  $\text{Li}_2\text{S}$  and  $\text{P}_2\text{S}_5$  in the EP medium.<sup>15</sup> Fig. 2 shows the XRD patterns of  $\text{Li}_2\text{S}$ ,  $\text{P}_2\text{S}_5$ , and the prepared samples. The  $\text{Li}_2\text{S}$  pattern exhibits peaks at  $2\theta \approx 26^\circ$  and  $31^\circ$ , while  $\text{P}_2\text{S}_5$  appears nearly amorphous to XRD. The residue pattern after solvent removal at room temperature (S-RT) shows many peaks that do not correspond to known crystal structures. The absence of  $\text{Li}_2\text{S}$  in the S-RT pattern indicates that  $\text{Li}_2\text{S}$  has completely reacted with  $\text{P}_2\text{S}_5$  in the EP medium. The pattern of the sample

obtained after heating S-RT at 190 °C for 1 h (S-190) was nearly amorphous to XRD. Notably, it has been reported that the XRD pattern of 70Li<sub>2</sub>S–30P<sub>2</sub>S<sub>5</sub> recovered from EA after heating at 100 °C showed the crystal structure of β-Li<sub>3</sub>PS<sub>4</sub>.<sup>12</sup> The patterns of the samples obtained after heating S-190 at 230 °C and 240 °C for 1 h (S-230, S-240) exhibit peaks consistent with β-Li<sub>3</sub>PS<sub>4</sub> and Li<sub>7</sub>P<sub>3</sub>S<sub>11</sub>.<sup>15,22</sup> The patterns obtained after heating S-190 at 250 °C for 1 h (S-250) displays features of Li<sub>7</sub>P<sub>3</sub>S<sub>11</sub> along with some peaks of Li<sub>4</sub>P<sub>2</sub>S<sub>6</sub>.<sup>23–25</sup> The formation of Li<sub>7</sub>P<sub>3</sub>S<sub>11</sub> in S-250 was consistent with the TG-DTA results, confirming that EP is an effective medium for synthesizing Li<sub>7</sub>P<sub>3</sub>S<sub>11</sub>.

Fig. S3 shows the Raman spectra of the precipitate obtained after decanting the yellow supernatant (Fig. S1), with the spectra of EP, Li<sub>2</sub>S, and P<sub>2</sub>S<sub>5</sub> included for comparison. The inset highlights an enlarged view of the white precipitate spectrum, which displays an intense peak at approximately 421 cm<sup>−1</sup>, indicating the presence of PS<sub>4</sub><sup>3−</sup> ion.<sup>26</sup> No Li<sub>2</sub>S signal was detected in the spectrum of the white precipitate, confirming the complete

Fig. 3 Raman spectra of Li<sub>2</sub>S, P<sub>2</sub>S<sub>5</sub>, and the prepared samples S-RT, S-190, S-230, S-240, and S-250. The figure on the right-hand side shows the enlargement in the range of 3050 to 2800 cm<sup>−1</sup> of the spectra of S-RT and S-190.

consumption of  $\text{Li}_2\text{S}$  in the reaction with  $\text{P}_2\text{S}_5$ . Fig. 3 shows the Raman spectra of  $\text{Li}_2\text{S}$ ,  $\text{P}_2\text{S}_5$ , and the prepared samples S-RT, S190, S-230, S-240, and S250. The inset on the left shows an enlarged view of the  $3100\text{--}2800\text{ cm}^{-1}$  region for the S-RT and S-190 spectra. The  $\text{Li}_2\text{S}$  spectrum exhibited a single intense peak at  $370\text{ cm}^{-1}$ , while the  $\text{P}_2\text{S}_5$  spectrum exhibited multiple peaks between  $150$  and  $320\text{ cm}^{-1}$ . The S-RT spectrum shows peaks at  $406$ ,  $420$ ,  $2940$ , and  $2965\text{ cm}^{-1}$ , with no main peaks from  $\text{Li}_2\text{S}$  or  $\text{P}_2\text{S}_5$  detected, indicating a complete reaction between  $\text{Li}_2\text{S}$  and  $\text{P}_2\text{S}_5$ . This observation is consistent with the XRD results. The peaks at  $2940$  and  $2965\text{ cm}^{-1}$  correspond to  $\text{CH}_3$  group vibrations in EP.<sup>15</sup> The peaks at  $406$  and  $420\text{ cm}^{-1}$  are attributed to the local structure units of  $\text{P}_2\text{S}_7^{4-}$  and  $\text{PS}_4^{3-}$  in  $\text{Li}_4\text{P}_2\text{S}_7$  and  $\text{Li}_3\text{PS}_4$ , respectively.<sup>26</sup> The S-190 spectrum exhibits peaks at  $402$  and  $416\text{ cm}^{-1}$ , indicating the presence of  $\text{P}_2\text{S}_7^{4-}$  and  $\text{PS}_4^{3-}$  in  $\text{Li}_4\text{P}_2\text{S}_7$  and  $\text{Li}_3\text{PS}_4$ , respectively. The absence of  $\text{CH}_3$  vibration peaks indicates the effective removal of EP after heating at  $190^\circ\text{C}$  for  $1\text{ h}$ . The positions of the  $\text{PS}_4^{3-}$  and  $\text{P}_2\text{S}_7^{4-}$  peaks in S-190 were shifted relative to those in the S-RT sample, indicating strong interactions between  $\text{Li}_3\text{PS}_4$  and  $\text{Li}_4\text{P}_2\text{S}_7$  with the EP solvent molecules. This observation suggests that EP removal from S-RT resulted in the formation of an amorphous structure in S-190, which is consistent with the XRD results. The spectra of S-230 and S-240 show the presence of  $\text{P}_2\text{S}_7^{4-}$  and  $\text{PS}_4^{3-}$  with peaks at  $402$  and  $417\text{ cm}^{-1}$ , respectively. The spectrum of S-250 exhibits peaks at  $417$ ,  $401$ , and  $379\text{ cm}^{-1}$ , corresponding to the local structure units of  $\text{PS}_4^{3-}$  and  $\text{P}_2\text{S}_7^{4-}$  in  $\text{Li}_7\text{P}_3\text{S}_{11}$ , and  $\text{P}_2\text{S}_6^{4-}$  in  $\text{Li}_4\text{P}_2\text{S}_6$ , respectively.<sup>8,26,27</sup> These Raman results confirm the

presence of  $\text{Li}_7\text{P}_3\text{S}_{11}$  and  $\text{Li}_4\text{P}_2\text{S}_6$  phases in S-250, which is consistent with the XRD measurements.

Powder XRD is effective for identifying crystalline phases but cannot characterize amorphous components. Therefore,  $^{31}\text{P}$  NMR was employed as a complementary technique to investigate the local structure of samples S-240 and S-250 (Fig. 4a and b, respectively). The S-240 spectrum exhibited peaks at the characteristic positions of the  $\text{PS}_4^{3-}$  and  $\text{P}_2\text{S}_7^{4-}$  groups in  $\text{Li}_7\text{P}_3\text{S}_{11}$ .<sup>28–30</sup> The deconvolution result revealed peaks at  $86.9$ ,  $87.8$ ,  $88.9$ , and  $91.7\text{ ppm}$ . The peak at  $86.9\text{ ppm}$  corresponds to  $\text{PS}_4^{3-}$  unit in  $\beta\text{-Li}_3\text{PS}_4$ ,<sup>31</sup> while the peaks at  $87.8$  and  $88.9\text{ ppm}$  are attributed to  $\text{PS}_4^{3-}$  and  $\text{P}_2\text{S}_7^{4-}$  units in  $\text{Li}_7\text{P}_3\text{S}_{11}$ , respectively.<sup>28–30</sup> The broad peak at  $91.7\text{ ppm}$  is attributed to the  $\text{P}_2\text{S}_7^{4-}$  group in amorphous  $\text{Li}_4\text{P}_2\text{S}_7$ ,<sup>32</sup> indicating the presence of  $\beta\text{-Li}_3\text{PS}_4$ ,  $\text{Li}_7\text{P}_3\text{S}_{11}$ , and amorphous  $\text{Li}_4\text{P}_2\text{S}_7$  in S-240. The S-250 spectrum exhibits peaks at the characteristic positions of the  $\text{PS}_4^{3-}$  and  $\text{P}_2\text{S}_7^{4-}$  groups in  $\text{Li}_7\text{P}_3\text{S}_{11}$  and  $\text{P}_2\text{S}_6^{4-}$  in  $\text{Li}_4\text{P}_2\text{S}_6$ .<sup>28–30</sup> The deconvolution result revealed peaks at  $86.3$ ,  $87.8$ ,  $89.9$ ,  $91.8$ ,  $105.2$ , and  $108.7\text{ ppm}$ . The peak at  $86.3\text{ ppm}$  corresponds to the  $\text{PS}_4^{3-}$  of the structural unit in  $\beta\text{-Li}_3\text{PS}_4$ .<sup>31</sup> The peaks at  $87.8$  and  $89.9\text{ ppm}$  are attributed to  $\text{PS}_4^{3-}$  and  $\text{P}_2\text{S}_7^{4-}$  groups in  $\text{Li}_7\text{P}_3\text{S}_{11}$ , respectively, while the broad peak at  $91.7\text{ ppm}$  arises from  $\text{P}_2\text{S}_7^{4-}$  group in amorphous  $\text{Li}_4\text{P}_2\text{S}_7$ . Notably, the area ratio between the  $\text{P}_2\text{S}_7^{4-}$  peak in amorphous  $\text{Li}_4\text{P}_2\text{S}_7$  and  $\text{Li}_7\text{P}_3\text{S}_{11}$  of S-250 is smaller than that of S-240, indicating the transformation of amorphous  $\text{Li}_4\text{P}_2\text{S}_7$  into crystalline  $\text{Li}_7\text{P}_3\text{S}_{11}$ . The peaks at  $105.2$  and  $108.7\text{ ppm}$  correspond to the  $\text{P}_2\text{S}_6^{4-}$  structural unit in  $\text{Li}_4\text{P}_2\text{S}_6$  (ref. 32–34). The formation of  $\text{Li}_4\text{P}_2\text{S}_6$

Table 1 Summary of the liquid-phase processing data of  $\text{Li}_7\text{P}_3\text{S}_{11}$  solid electrolytes

Solvent	Ionic conductivity ( $25^\circ\text{C}$ )/ $\text{S cm}^{-1}$	Processing temperature/ $^\circ\text{C}$	Activation energy $E_a/\text{eV}$	Electrochemical window/V vs. $\text{Li}^+/\text{Li}$	Reference
ACN	$9.7 \times 10^{-4}$	250	0.323	5.0	10
EA	$1.05 \times 10^{-3}$	260	—	—	12
EP	$1.5 \times 10^{-3}$	250	0.27	5.0	This work

Fig. 5 (a) The impedance spectra of S-250 obtained at various temperatures from around room temperature (20 °C) to 125 °C; (b) temperature dependence of the ionic conductivity of S-240 and S-250.

suggests that amorphous  $\text{Li}_4\text{P}_2\text{S}_7$  was partially decomposed during the heat treatment at 250 °C. These findings are consistent with the XRD and Raman results.

Fig. 5a shows the impedance spectra of S-250 over a frequency range of 10 Hz–10 MHz at temperatures ranging from 20 °C to 125 °C. At 20 °C, the spectrum displays a semicircle and a low-frequency tail, which is consistent with the  $\text{Li}^+$  blocking effect, indicating the ionic conductivity. The diameter of the semicircle decreases with increasing temperature and becomes almost negligible at 50 °C. The total impedance of the electrolyte pellet was determined from the intersection of the semicircle and the x-axis in the intermediate frequency region.<sup>35</sup> The temperature-dependent ionic conductivities of S-240 and S-250 were calculated from the total impedance values and are plotted in Fig. 5b. Notably,  $\log_{10} \sigma$  exhibits an almost linear dependence on the inverse temperature, following the Arrhenius equation  $\sigma = \sigma_0 \exp(-E_a/(k_B T))$ . The ionic conductivities of S-240 and S-250 at 25 °C are  $7.2 \times 10^{-4}$  and  $1.5 \times 10^{-3} \text{ S cm}^{-1}$ , respectively. These values are comparable to the reported values of conductivities for  $\text{Li}_7\text{P}_3\text{S}_{11}$  synthesized via liquid-phase methods using ACN and EA, which are higher than those obtained with 1,2-dimethoxyethane (Table 1).<sup>10,12,13</sup> The calculated activation energies  $E_a$  for S-240 and S-250 are 0.18 and 0.27 eV,

respectively. Previous studies have reported that a higher crystalline fraction of  $\text{Li}_7\text{P}_3\text{S}_{11}$  enhances ionic conductivity and reduces  $E_a$ ,<sup>30</sup> whereas the presence of  $\text{Li}_4\text{P}_2\text{S}_6$  in  $\text{Li}_7\text{P}_3\text{S}_{11}$  increases  $E_a$ .<sup>36</sup> The area fractions of amorphous  $\text{Li}_4\text{P}_2\text{S}_7$ , crystalline  $\text{Li}_7\text{P}_3\text{S}_{11}$ ,  $\text{Li}_4\text{P}_2\text{S}_6$ , and  $\beta\text{-Li}_3\text{PS}_4$  were calculated to evaluate the effect of  $\text{Li}_4\text{P}_2\text{S}_6$  on the conductivity and activation energy of S-250 (Table 2). Therefore, the higher ionic conductivity of S-250 compared with S-240 is attributed to increased  $\text{Li}_7\text{P}_3\text{S}_{11}$  crystallinity, while its higher  $E_a$  is attributed to the presence of  $\text{Li}_4\text{P}_2\text{S}_6$ .

Fig. 6a shows the variation of DC with time when a voltage of 0.5 V (DC) was applied to the S-250 sample. With nonblocking electrodes, a constant current was observed, whereas blocking electrodes initially exhibited polarization followed by a nearly constant current. The current with nonblocking electrodes was approximately four orders of magnitude higher than that with blocking electrodes, indicating that S-250 is a single-ion conductor with a lithium-ion transport number estimated to be higher than 0.999. Fig. 6b shows the cyclic voltammogram of S-250. The small inset shows an enlarged cyclic voltammetry curve in the range of 2.0–5.0 V vs.  $\text{Li}^+/\text{Li}$ . The cathodic current, corresponding to the Li reduction, started at approximately 0 V, confirming the stability of the prepared SE against Li metal. Except for the cathodic anodic peaks, no additional peaks were observed within the scanned range, indicating the compatibility of the S-250 with Li metal up to 5 V vs.  $\text{Li}^+/\text{Li}$ .

Fig. 7a shows SEM-EDS images of the prepared LIC@NMC111 and S-250 mixture, illustrating that the SE particles are well-distributed among NMC111 particles. To assess the compatibility of S-250 with high-voltage SSBs, NMC111 was employed as the active material to evaluate cycling performance at a constant current of 0.1C in the voltage range of 2.4–3.7 V vs. Li–In at room temperature (Fig. 7b). The charge-discharge capacities of the 1st cycle were 122 and 101 mAh  $\text{g}_{\text{NMC}}^{-1}$ . In the 10th cycle, the capacities were 138 and 137 mAh

Table 2 Area fraction of the NMR peaks for S-240 and S-250

Sample	Phase	Area (%)
S-240	$\text{Li}_4\text{P}_2\text{S}_7$ amorphous	49.6
	$\text{Li}_7\text{P}_3\text{S}_{11}$	21.8
	$\beta\text{-Li}_3\text{PS}_4$	28.6
S-250	$\text{Li}_4\text{P}_2\text{S}_7$ amorphous	13.5
	$\text{Li}_7\text{P}_3\text{S}_{11}$	69.4
	$\beta\text{-Li}_3\text{PS}_4$	5.5
	$\text{Li}_4\text{P}_2\text{S}_6$	11.6

Fig. 6 (a) Change in DC with time when a voltage of 0.5 V (DC) was applied to the S-250 sample; (b) cyclic voltammogram of S-250 obtained at a scan rate of  $5 \text{ mV s}^{-1}$  between 0.5 and 5 V.

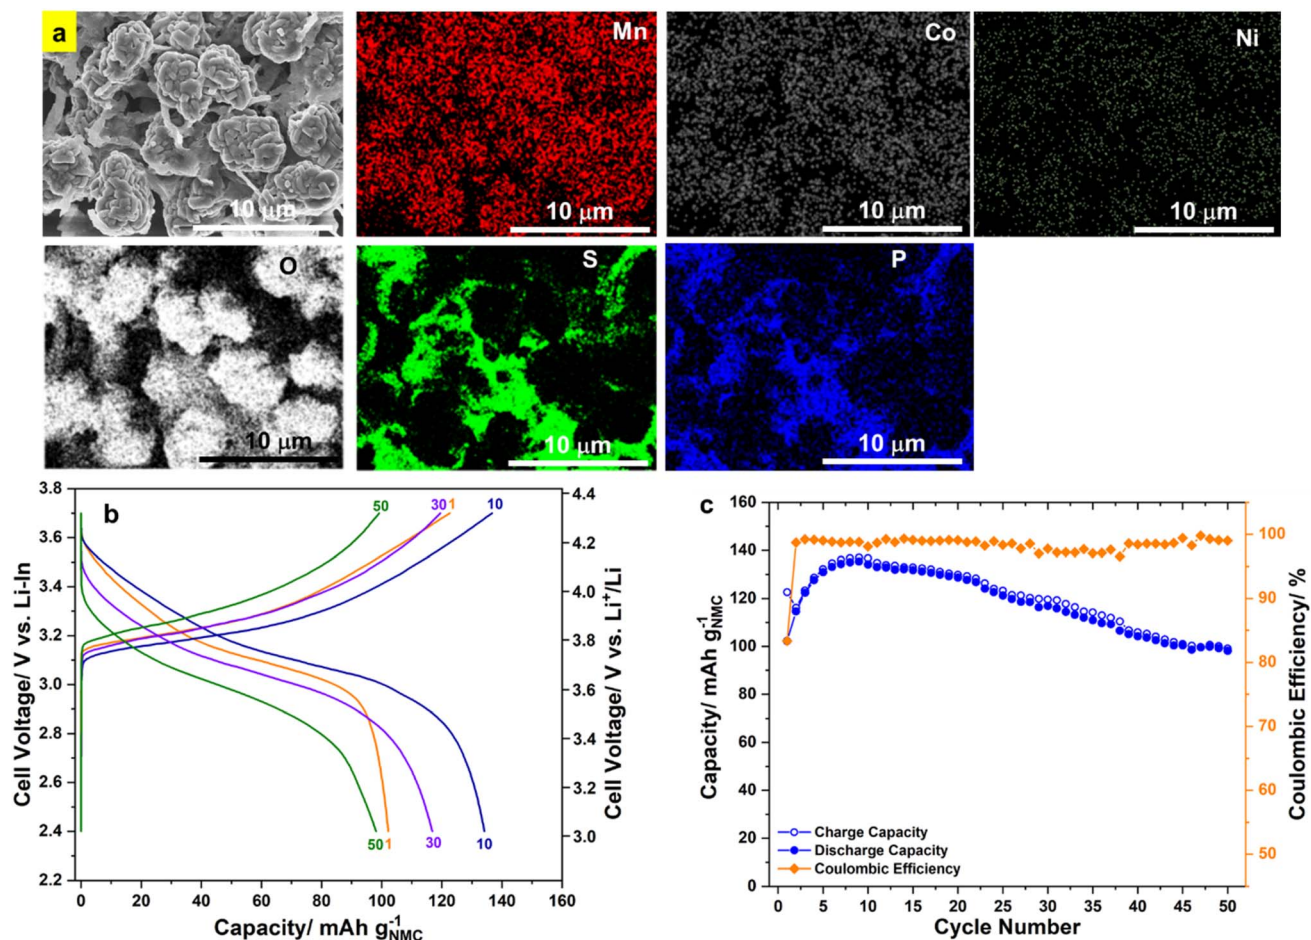

Fig. 7 (a) SEM-EDS images of the mixture of LIC@NMC11 and S-250; (b) 1st, 10th, 30th, and 50th charge–discharge curves of the prepared solid-state cell cycling at 0.1C between 3.7 and 2.4 V vs.  $\text{Li-In}$ ; (c) charge–discharge capacities and CE of the prepared cell for 50 cycles.

$\text{g}_{\text{NMC}}^{-1}$ , which were slightly higher than those of the 1st cycle. At the 30th cycle, the capacities were 120 and 119  $\text{mAh g}_{\text{NMC}}^{-1}$ , respectively. The initial coulombic efficiency (CE) was

approximately 83%. From 2nd cycle onwards, the CE was higher than 99%, indicating cell stability. Fig. 7c illustrates the charge–discharge capacities and CE of the prepared cell over 50 cycles,

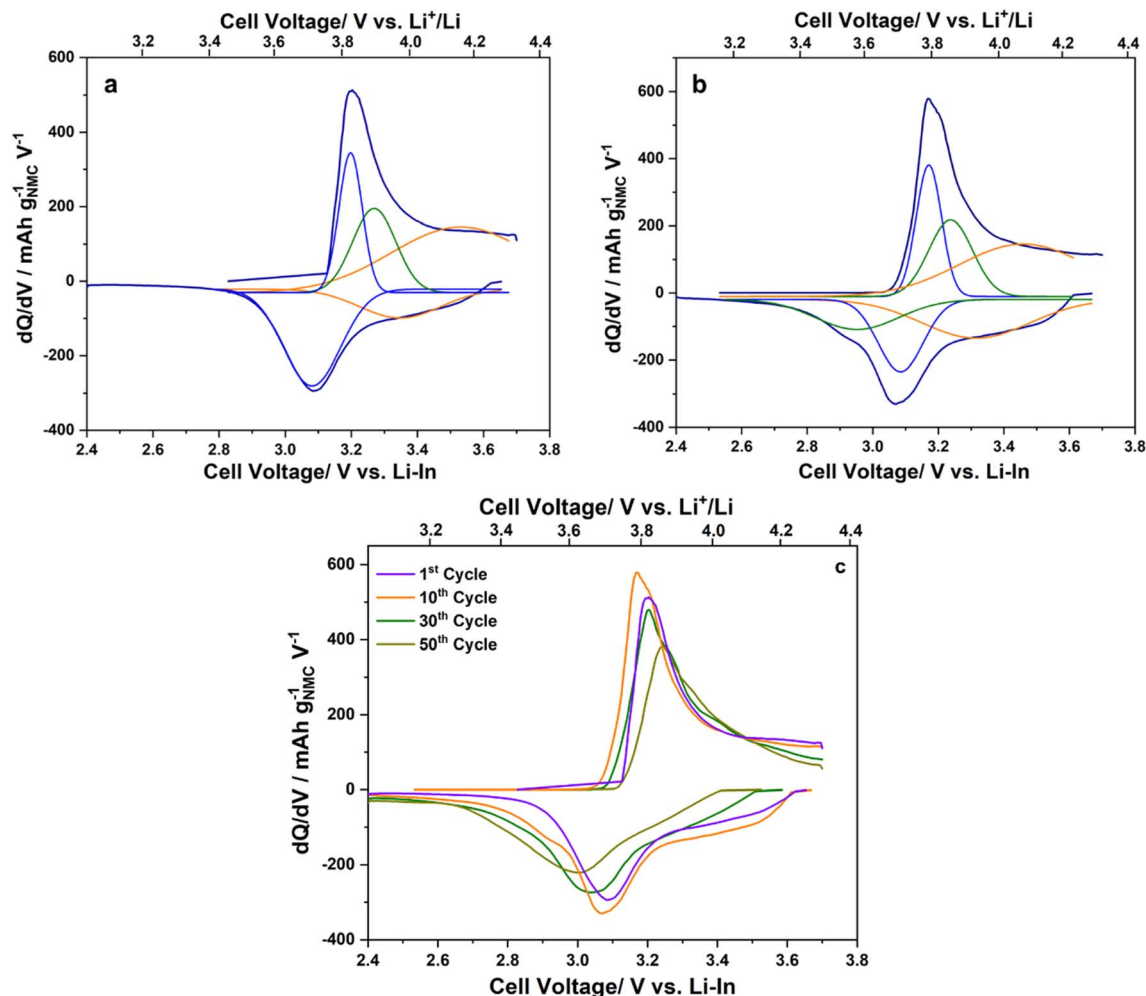

Fig. 8  $dQ/dV$  curves of the NMC111 cathode at different cycles: (a) 1st, (b) 10th, (c) 1st, 10th, 30th, and 50th.

with the discharge capacity of the 50th-cycle nearly identical to that of the 1st cycle, further confirming the stability of the cell. These results demonstrate that the prepared S-250 SE is a promising candidate for SSBs.

Fig. 8 shows the differential capacity curves ( $dQ/dV$ ) of the NMC111 cathode at different cycles to analyze the evolution of the voltage profile. In the 1st cycle (Fig. 8a), distinct redox peaks at 3.81/3.71 V vs.  $\text{Li}^+/\text{Li}$  were observed, attributed to  $\text{Ni}^{3+}/\text{Ni}^{4+}$  oxidation/reduction associated with Li de-insertion/insertion.<sup>37,38</sup> In the 10th cycle (Fig. 8b), these peaks shifted slightly to 3.80/3.70 V vs.  $\text{Li}^+/\text{Li}$ . Subsequently, the oxidation and reduction peaks shifted toward higher and lower voltage regions, respectively, indicating continuous capacity degradation (Fig. 8c). The redox peaks at 4.18/3.95 V vs.  $\text{Li}^+/\text{Li}$  in the 1st cycle are attributed to  $\text{Co}^{4+}/\text{Co}^{3+}$  oxidation/reduction.<sup>37,38</sup> These peaks shifted to the lower voltage region, which were again consistent with continuous capacity degradation. These results indicate that the electrode polarization increases with cycling. The redox peaks at about 3.84/3.55 V vs.  $\text{Li}^+/\text{Li}$  observed in the 10th cycle, which was gradually shifted to lower voltage region, is related to the oxidation/reduction of  $\text{Ni}^{3+}/\text{Ni}^{2+}$ .<sup>38,39</sup> These peaks were not clearly visible in the 1st cycle, and their

appearance correlates with the increase in capacity from the 1st to the 10th cycle.

## 4. Conclusion

This study demonstrates that  $\text{Li}_7\text{P}_3\text{S}_{11}$  SEs can be synthesized using EP to promote the reaction between  $\text{Li}_2\text{S}$  and  $\text{P}_2\text{S}_5$ . The residue obtained after solvent removal at 190 °C is amorphous to XRD, but Raman spectroscopy confirms the presence of  $\text{PS}_4^{3-}$  and  $\text{P}_2\text{S}_7^{4-}$  groups. Heating this residue at 230 °C, 240 °C, and 250 °C leads to the formation of  $\text{Li}_7\text{P}_3\text{S}_{11}$  SE.  $^{31}\text{P}$  NMR spectra results indicate that amorphous  $\text{Li}_4\text{P}_2\text{S}_7$  reacts with  $\beta\text{-Li}_3\text{PS}_4$  to yield  $\text{Li}_7\text{P}_3\text{S}_{11}$ . The prepared  $\text{Li}_7\text{P}_3\text{S}_{11}$  SE exhibited an ionic conductivity of  $1.5 \times 10^{-3} \text{ S cm}^{-1}$  at 25 °C with an activation energy of 0.27 eV. The electrochemical measurements show that the prepared SE is stable up to 5.0 V vs.  $\text{Li}^+/\text{Li}$ , demonstrating its suitability for SSB applications.
