Influence of C3'- and C4'-substitutions on fluorescence, crystal packing, and physicochemical properties of flavonol

Oleksii O. Demidov,^a Ludmila V. Chepeleva,^a Svitlana V. Shishkina,^{bc} Eugene S. Gladkov,^{ab} Alexander Kyrychenko,^{*ab} Rostyslav P. Linnik^d and Alexander D. Roshal^a

Natural flavonols exhibit a wide range of pharmacological activities and possess unique dual ESIPT (Excited-State Intramolecular Proton Transfer) fluorescence, making them sensitive to microenvironments. This sensitivity allows for the detection of metal ions, anions, small ligands, and biomacromolecules. However, the diversity in their structure, including the number and position of hydroxyl groups and potential chemical modifications, complicates the relationship between structure and fluorescence, posing challenges for their practical use as fluorescent probes. In this study, we focus on fine-tuning the ESIPT fluorescence, crystal packing, physicochemical properties, and ADMET (Absorption, Distribution, Metabolism, Excretion, and Toxicity) characteristics of a series of flavonols. We achieve this by introducing hydroxy, methoxy and benzyl groups at the C3' and C4' positions of the 2-phenyl side ring. The photophysical properties of the synthesized flavonols were systematically examined by UV-vis and fluorescence measurements in terms of their structure–property relationship. Our findings indicate that the nature and position of the substituent groups in flavonols can significantly influence their crystal packing in the solid state, tuning contributions of intra- and intermolecular hydrogen bonding and the ESIPT behavior. Lastly, through fluorescence titration and molecular docking calculations, we explored how the introduction of a bulky benzyl moiety and its alteration between C3' and C4' positions can influence the binding interactions of flavonols with β -glucosidases. We believe our findings shed light on the structure–fluorescence relationship in flavonols and open up new opportunities for the design of innovative flavonol-based probes.

Introduction

Flavonols are widely distributed compounds found in nature, primarily as secondary metabolites of plants and fungi.¹ These substances possess a variety of biological effects, making them of great interest to pharmaceutical researchers.² They are known for their strong antioxidant and cancerostatic properties, and their P-vitamin activity.^{1,2} Additionally, flavonols serve as effective models for studying intramolecular excited-state proton transfer (ESIPT) processes.^{3–8} The phototautomerization of flavonols leads to the formation of two distinct emission bands in fluorescence spectra. The intensity ratio of these bands—corresponding to the initial excited form

and the phototautomer — depends not only on the structure of the flavonol compounds but also on external factors like the polarity of the surrounding environment and specific interactions with solvent molecules.^{3,9–14} Due to their properties, flavonols can serve as sensors in biochemical and medicobiological studies.^{9,15,16} The 7-hydroxy group in flavones can undergo photodissociation, resulting in fluorescent anions when the corresponding flavones are in an excited state.^{17,18} In the case of 7-hydroxyflavonols, photodissociation occurs alongside excited-state intramolecular proton transfer (ESIPT), leading to the formation of more complex protolytic forms known as anion-tautomers.¹⁹ The fluorescence of mentioned flavonol molecules is utilized to study micelles and cell membranes.^{20–22} Additionally, flavonols possess one to four complexation centers, enabling them to function as fluorescent indicators for detecting metal ions.^{21,23,24} They also may act as ligands that enhance the efficient extraction of metal ions into the organic phase.²⁵

All the manifestations of flavonols' reactivity share common characteristics in terms of their spectral and pharmacological effects. These changes in flavonol structures, such as photodissociation, photoisomerization, complex formation, and

interactions with surrounding molecules, typically involve the chromone fragment of the molecule.²⁴ The effects of the side phenyl ring and its substituents on the reactivity, spectral, and pharmacological properties have not been thoroughly studied.

The introduction of strong electron-donating and electron-accepting groups, such as alkylamino substituents or nitro groups, into the side ring can result in significant interfragment charge transfer (ICT) between the phenyl and chromone fragments. This transfer leads to the appearance of new long-wavelength absorption bands in the spectra, attributed to the charge-transfer transition, along with changes in the fluorescence characteristics. Natural and many synthetic flavonols typically contain less effective electron-donating substituents, such as hydroxy or various alkoxy groups.⁸ Their impact on the spectral properties of flavonols, as previously noted, has not been thoroughly studied. Additionally, our recent studies indicate that flavonols with lipophilic alkoxy substituents on the side phenyl ring can effectively bind to hydrolase enzymes, such as glucosidases, and inhibit their catalytic activity.^{21,26}

Physicochemical and pharmacological properties of flavonols have complex interplay on the position and number of hydroxyl groups, as well as their chemical modifications.² Therefore, in this study, we focus on some flavonols with various combinations of substituents in the C3' and C4' positions of the side benzene ring. The introduction of methoxy and benzyl groups and altering their positions aimed to establish the relationship between the structure and fluorescent properties of flavonols. Our study demonstrates how the nature and position of substituents in the side ring affect the structure of flavonol molecules in both gas and crystalline phases. It also discusses how these factors influence the position of bands in absorption spectra, as well as the position and intensity ratio of emission bands for both the original and photo-tautomeric forms in fluorescence spectra. Finally, we consider how peripheral phenyl ring substitutions can tune the binding interactions with proteins.

Experimental section

Chemistry

To study the effect of the C3' and C4' substitutions in the flavonol's side benzene ring on fluorescence, crystal packing,

physicochemical and ADMET properties the following flavonols were considered (Scheme 1).

Structure of unsubstituted flavonol **3** and synthesized flavonol derivatives **3a–m** are summarized in Scheme 1. Unsaturated ketones (**2a–c**, **g–m**), used as precursors, were obtained by a modified known methods (Scheme 2).^{27,28} Preliminary spectral analysis was provided by Enamine Ltd (Ukraine). All solvents and reagents were commercial grade and, if required, purified in accordance with the standard procedures.

General procedure of synthesis of chalcones (**2a–c**, **g–m**)

To a suspension of NaH (5.2 mmol, 60% dispersion in mineral oil) in DMF (20 mL), under a nitrogen atmosphere at 0 °C added drop wisely 2'-hydroxyacetophenone (4 mmol). The resulting mixture stirred at 0 °C for 10 min. A solution of corresponding benzaldehyde (4 mmol) in DMF (10 mL) was added drop wisely in the mixture and stirred at room temperature for 2 hours. Therefore, the mixture was acidified drop wisely with glacial acetic acid until pH 4. After filtration the precipitate washed with MeOH (10 mL). The resulting solid was concentrated under vacuum to obtain a crud product with uses in next stage without purification.

General procedure of synthesis of flavonols (**3a–c**, **g–m**)

To a suspension of chalcone **2a–c**, **g–m** (6 mmol) in MeOH (30 mL) was added KOH (15 mmol), the reaction mixture stirred at –15 °C for 10 min. Then 30% H₂O₂ (18 mmol) was drop wisely added in the mixture and stirred at rt for 2.5 hours. Therefore, the mixture was acidified drop wisely with glacial acetic acid until pH 2. After filtration the precipitate washed with MeOH (10 mL). The resulting solid was concentrated under vacuum to obtain a pure product. The synthesis scheme is summarized in Scheme 2 and Table 1.

General procedure of synthesis of flavonols (**3d–f**)

The flavonols **3k–m** (3 mmol) was dissolved in THF (40 mL) and 300 mg of Pd/C 10% was added. The mixture was stirred for 12 h at room temperature under hydrogen atmosphere. The Pd/C was filtered off. After the solvent was evaporated, the precipitate washed with MeOH (10 mL) and filtered. The resulting solid was concentrated under vacuum to obtain a pure product.

4'-Hydroxyflavonol (3-hydroxy-2-(4-hydroxyphenyl)-4H-chromen-4-one) (3a).²⁹ ¹H NMR (500 MHz, DMSO-*d*₆), δ , ppm: 10.08 (s, 1H), 9.33 (s, 1H), 8.10 (t, *J* = 7.7 Hz, 3H), 7.79–7.72 (m, 2H), 7.44 (s, 1H), 6.93 (d, *J* = 8.3 Hz, 2H). ¹³C NMR (126 MHz, DMSO-*d*₆), δ , ppm: 172.5, 159.1, 154.4, 146.1, 137.8, 133.3, 129.5, 124.7, 124.4, 122.0, 121.3, 118.2, 115.4 (SI Fig. S1). Mass spectrum, *m/z* (*I*_{rel}, %): 253.0 [*M* – H]–(100) (SI Fig. S14).

4'-Methoxyflavonol (3-hydroxy-2-(4-methoxyphenyl)-4H-chromen-4-one) (3b).²⁹ ¹H NMR (500 MHz, DMSO-*d*₆), δ , ppm: 9.46 (s, 1H), 8.20 (d, *J* = 8.6 Hz, 2H), 8.10 (d, *J* = 8.0 Hz, 1H), 7.82–7.72 (m, 2H), 7.45 (t, *J* = 7.4 Hz, 1H), 7.13 (d, *J* = 8.6 Hz, 2H), 3.84 (s, 3H). ¹³C NMR (126 MHz, DMSO-*d*₆), δ , ppm: 172.6, 160.4, 154.4, 145.5, 138.1, 133.4, 129.4, 124.7, 124.4, 123.5, 121.3, 118.3, 114.0, 55.3 (Fig. S2). Mass spectrum, *m/z* (*I*_{rel}, %): 157.0 (100), 269.0 [*M* + 1]⁺ (55) (Fig. S15).

4'-Benzyloxyflavonol (2-(4-(benzyloxy)phenyl)-3-hydroxy-4H-chromen-4-one) (3c).²⁶ ¹H NMR (500 MHz, DMSO-*d*₆), δ , ppm: 9.31 (s, 1H), 8.18 (d, 2H), 8.09 (d, *J* = 8.2 Hz, 1H), 7.79–7.68 (m, 2H), 7.49–7.29 (m, 6H), 7.18 (d, *J* = 8.0 Hz, 2H), 5.18 (d, *J* = 2.5 Hz, 2H). ¹³C NMR (126 MHz, DMSO-*d*₆), δ , ppm: 172.6, 159.5, 154.4, 145.5, 138.2, 136.6, 133.4, 129.3, 128.4, 127.9, 127.7, 124.7, 124.4, 123.8, 121.3, 118.3, 114.8, 69.4 (Fig. S3). Mass spectrum, *m/z* (*I*_{rel}, %): 345.2 [*M* + 1]⁺ (92), 367.2(8) (Fig. S16).

3'-Hydroxyflavonol (3-hydroxy-2-(3-hydroxy-4-methoxyphenyl)-4H-chromen-4-one) (3d).²⁹ ¹H NMR (400 MHz, DMSO-*d*₆), δ , ppm: 9.29–9.21 (m, 2H), 8.11 (dd, *J* = 8.0, 1.6 Hz, 1H), 7.82–7.67 (m, 4H), 7.45 (t, *J* = 7.4 Hz, 1H), 7.10 (d, *J* = 8.6 Hz, 1H), 3.86 (s, 3H). ¹³C NMR (101 MHz, DMSO-*d*₆), δ , ppm: 172.5, 154.4, 149.3, 146.2, 145.6, 138.2, 133.4, 124.7, 124.4, 123.7, 121.3, 119.7, 118.2, 114.8, 111.8, 55.6 (Fig. S4). Mass spectrum, *m/z* (*I*_{rel}, %): 157.0 (100), 239.2 (23), 255.0 [*M* + 1]⁺ (55) (Fig. S17).

3',4'-Dihydroxyflavonol (2-(3,4-dihydroxyphenyl)-3-hydroxy-4H-chromen-4-one) (3e).³⁰ ¹H NMR (400 MHz, DMSO-*d*₆), δ , ppm: 9.39 (s, 3H), 8.09 (dd, *J* = 7.9, 1.7 Hz, 1H), 7.80–7.66 (m, 3H), 7.61 (dd, *J* = 8.4, 2.2 Hz, 1H), 7.43 (t, *J* = 7.4 Hz, 1H), 6.91 (d, *J* = 8.4 Hz, 1H). ¹³C NMR (101 MHz, DMSO-*d*₆), δ , ppm: 172.9, 154.8, 148.1, 146.6, 145.6, 138.4, 133.8, 125.2, 124.8,

122.8, 121.8, 120.5, 118.6, 116.1, 115.8 (Fig. S5). Mass spectrum, *m/z* (*I*_{rel}, %): 271.0 [*M* + 1]⁺ (88), 272.0 (8) (Fig. S18).

3'-Hydroxy-4'-methoxyflavonol (3-hydroxy-2-(3-hydroxy-4-methoxyphenyl)-4H-chromen-4-one) (3f).³¹ ¹H NMR (400 MHz, DMSO-*d*₆), δ , ppm: 9.29–9.21 (m, 2H), 8.11 (dd, *J* = 8.0, 1.6 Hz, 1H), 7.82–7.67 (m, 4H), 7.45 (t, *J* = 7.4 Hz, 1H), 7.10 (d, *J* = 8.6 Hz, 1H), 3.86 (s, 3H). ¹³C NMR (101 MHz, DMSO-*d*₆), δ , ppm: 172.5, 154.4, 149.3, 146.2, 145.6, 138.2, 133.4, 124.6, 124.4, 123.7, 121.3, 119.7, 118.2, 114.8, 111.8, 55.6 (Fig. S6). Mass spectrum, *m/z* (*I*_{rel}, %): 285.2 [*M* + 1]⁺ (94), 286.2 (6) (Fig. S19).

3'-Methoxyflavonol (3-hydroxy-2-(3-methoxyphenyl)-4H-chromen-4-one) (3g).²⁹ ¹H NMR (400 MHz, DMSO-*d*₆), δ , ppm: 9.66 (s, 1H), 8.12 (d, *J* = 7.6 Hz, 1H), 7.86–7.75 (m, 5H), 7.53–7.43 (m, 3H), 7.10 (dd, *J* = 8.2, 2.6 Hz, 1H), 3.83 (s, 4H). ¹³C NMR (126 MHz, DMSO-*d*₆), δ , ppm: 173.5, 159.7, 155.0, 145.3, 139.7, 134.3, 133.0, 130.2, 125.3, 125.1, 121.7, 120.5, 119.0, 115.7, 113.9, 55.7 (Fig. S7). Mass spectrum, *m/z* (*I*_{rel}, %): 269.0 [*M* + 1]⁺ (93), 270.0 (7) (Fig. S20).

4'-Hydroxy-3'-methoxyflavonol (3-hydroxy-2-(4-hydroxy-3-methoxyphenyl)-4H-chromen-4-one) (3h).³² ¹H NMR (500 MHz, DMSO-*d*₆), δ , ppm: 9.55 (s, 2H), 8.09 (d, *J* = 7.9 Hz, 1H), 7.83 (s, 1H), 7.80–7.73 (m, 3H), 7.50–7.40 (m, 1H), 6.96 (dd, *J* = 8.5, 3.7 Hz, 1H), 3.86 (s, 3H). ¹³C NMR (126 MHz, DMSO-*d*₆), δ , ppm: 172.5, 154.3, 148.7, 147.4, 145.9, 138.0, 133.3, 124.6, 124.4, 122.2, 121.8, 121.2, 118.3, 115.5, 111.7, 55.7 (Fig. S8). Mass spectrum, *m/z* (*I*_{rel}, %): 285.0 [*M* + 1]⁺ (96), 285.0(3) (Fig. S21).

3',4'-Dimethoxyflavonol (2-(3,4-dimethoxyphenyl)-3-hydroxy-4H-chromen-4-one) (3i).³³ ¹H NMR (500 MHz, DMSO-*d*₆), δ , ppm: 9.47 (s, 1H), 8.09 (d, *J* = 7.9 Hz, 1H), 7.86 (d, *J* = 8.6 Hz, 1H), 7.83–7.75 (m, 3H), 7.48–7.42 (m, 1H), 7.14 (d, *J* = 8.6 Hz, 1H), 3.84 (s, 6H). ¹³C NMR (151 MHz, DMSO-*d*₆), δ , ppm: 173.1, 154.9, 150.8, 148.9, 145.9, 138.7, 133.9, 125.2, 124.9, 124.1, 122.0, 121.7, 118.9, 112.0, 111.5, 56.1, 56.1 (Fig. S9). Mass spectrum, *m/z* (*I*_{rel}, %): 299.2 [*M* + 1]⁺ (91), 300.2 (15) (Fig. S22).

3'-Methoxy-4'-benzyloxyflavonol (2-(4-(benzyloxy)-3-methoxyphenyl)-3-hydroxy-4H-chromen-4-one) (3j).³⁴ ¹H NMR (500 MHz, DMSO-*d*₆), δ , ppm: 9.48 (s, 1H), 8.09 (d, *J* = 7.3 Hz, 1H), 7.86–7.72 (m, 4H), 7.50–7.30 (m, 6H), 7.22 (d, *J* = 8.8 Hz, 1H), 5.17 (s, 2H), 3.85 (s, 3H). ¹³C NMR (126 MHz, DMSO-*d*₆), δ , ppm: 172.6, 154.4, 149.3, 148.7, 145.3, 138.3, 136.7, 133.4, 128.4, 127.9, 127.9, 124.7, 124.4, 123.9, 121.3, 121.2, 118.3, 113.0, 111.3, 69.8, 55.7 (Fig. S10). Mass spectrum, *m/z* (*I*_{rel}, %): 375.2 [*M* + 1]⁺ (97), 397.2 (3) (Fig. S23).

3'-Benzyloxyflavonol (2-(3-(benzyloxy)phenyl)-3-hydroxy-4H-chromen-4-one) (3k). ¹H NMR (400 MHz, DMSO-*d*₆), δ , ppm: 9.69 (s, 1H), 8.11 (d, *J* = 8.0 Hz, 1H), 7.89–7.71 (m, 4H), 7.53–7.29 (m, 7H), 7.15 (dd, *J* = 8.4, 2.7 Hz, 1H), 5.17 (s, 2H). ¹³C NMR (126 MHz, DMSO-*d*₆), δ , ppm: 173.0, 158.2, 154.5, 144.7, 139.2, 136.8, 133.7, 132.5, 129.6, 128.4, 127.9, 127.8, 124.7, 124.5, 121.2, 120.2, 118.4, 115.9, 114.3, 69.4 (Fig. S11). White solid with a yellowish tint, mp 137–138 °C. Mass spectrum, *m/z* (*I*_{rel}, %): [*M* + H]⁺ = 345.0 [*M* + 1]⁺ (97), 346 (20) (Fig. S24).

3'-Benzyloxy-4'-methoxyflavonol (2-(3-(benzyloxy)-4-methoxyphenyl)-3-hydroxy-4H-chromen-4-one) (3l).³¹ ¹H NMR (400 MHz, DMSO-*d*₆), δ , ppm: 9.50 (s, 1H), 8.10 (dd, *J* = 8.0, 1.6 Hz, 1H), 7.94–7.87 (m, 2H), 7.84–7.72 (m, 2H), 7.55–7.30 (m, 6H), 7.21–7.14 (m, 1H), 5.18 (s, 2H), 3.86 (s, 3H). ¹³C NMR (126 MHz,

DMSO- d_6), δ , ppm: 172.6, 154.3, 150.6, 147.4, 145.3, 138.3, 136.9, 133.4, 128.4, 128.1, 127.9, 124.7, 124.5, 123.5, 121.9, 121.2, 118.3, 112.7, 111.7, 70.2, 55.6 (Fig. S12). Mass spectrum, m/z (I_{rel} , %): 375.0 $[M + 1]^+$ (88), 376.0 (12) (Fig. S25).

3',4'-Dibenzoylflavonol (2-(3,4-bis(benzoyloxy)phenyl)-3-hydroxy-4H-chromen-4-one) (3m).²⁶ ^1H NMR (500 MHz, DMSO- d_6), δ , ppm: 9.52 (s, 1H), 8.09 (d, $J = 8.0$ Hz, 1H), 7.94 (s, 1H), 7.87 (d, $J = 8.6$ Hz, 1H), 7.83–7.70 (m, 2H), 7.54–7.28 (m, 11H), 7.25 (d, $J = 8.7$ Hz, 1H), 5.22 (d, $J = 7.3$ Hz, 4H). ^{13}C NMR (126 MHz, DMSO- d_6), δ , ppm: 172.6, 154.3, 149.8, 147.7, 145.2, 138.4, 137.0, 136.8, 133.4, 128.4, 127.9, 127.8, 127.6, 124.7, 124.4, 123.9, 121.9, 121.2, 118.3, 113.7, 70.4, 69.9 (Fig. S13). Mass spectrum, m/z (I_{rel} , %): 451.0 $[M + 1]^+$ (74), 452.0 (16) (Fig. S26).

Quantum-chemical calculations

Unconstrained and constrained geometry optimizations of isolated molecules of flavonols in the ground electronic state and analysis of rotation barriers were carried out at the DFT levels of theory using the B3LYP functional³⁵ and cc-pVDZ basis set³⁶ implemented in the GAUSSIAN 16 program package.³⁷ The solvent (dichloromethane and acetonitrile) effect at 298.14 K and standard pressure was estimated at the level of the Polarized Continuum Model (PCM).³⁸

Spectroscopic measurements

NMR spectra. ^1H NMR spectra were recorded using Unity Inova 400, Bruker Avance DRX 500, and Bruker Avance III 400 MHz spectrometers in DMSO- d_6 . ^{13}C NMR spectra were recorded on Bruker Avance DRX 500 and Agilent ProPulse 500 MHz spectrometers at a resonance frequency of 126 MHz in DMSO- d_6 . Chemical shifts are reported in the δ scale (ppm). Mass spectra were recorded on an Agilent 1100 high-performance liquid chromatograph (HPLC) equipped with a diode matrix and an Agilent LC/MSD SL mass-selective detector, a SUPELCO Ascentis Express C18 chromatographic column 2.7 μm 4.6 mm \times 15 cm. Control over the course of the reaction and the individuality of the obtained substances was carried out by TLC method on silica gel-coated "Polychrom SI F254" plates with a fluorescent detector in the hexane–ethyl acetate 2 : 1 system, the developer was an ultraviolet lamp. If necessary, additional purification of the obtained compounds was carried out using flash chromatography (UPFP) on a PuriFlash XS520 Plus device using gradient elution. The melting points of all synthesized compounds were determined using a Hanon Instruments MP450 open capillary tube automatic melting point apparatus.

UV-vis and fluorescence spectra. Absorption and fluorescence spectra of flavonols in liquid media were registered in dichloromethane and acetonitrile solutions. Commercial solvents were additionally rectified and dried before use. The flavonols' concentrations in investigated solutions ranged from 1.0×10^{-5} to $5.0 \times 10^{-5} \text{ M l}^{-1}$. Absorption and fluorescence spectra were recorded on a PerkinElmer LS55 spectrofluorimeter and a Shimadzu UV-2401PC spectrophotometer. The latter was also used to record the excitation and fluorescence spectra of flavonols in the solid state.

Fluorescence titrations. The interaction between flavonols and protein molecules was studied using β -glucosidase (β -D-glucoside glucohydrolase) from Almonds purchased from Sigma-Aldrich as a lyophilized powder with > 98% purity. Stock solutions of flavonols were prepared by dissolving their samples in DMSO. A stock solution of β -glucosidase was prepared by dissolving a sample of the enzyme in an aqueous phosphate buffer with pH 6.86. The fluorescence was excited at 380 nm and the emission spectra were recorded in the range of 400–700 nm using a Hitachi 850 spectrofluorimeter. The experimental details are described elsewhere.³⁹

X-ray diffraction study. X-Ray diffraction studies were performed on an automatic "Bruker APEX II" diffractometer (graphite monochromated MoK α radiation, CCD-detector, ϕ - and ω -scanning). The structures were solved by direct method using OLEX2 ref. 40 package with SHELXT⁴¹ and SHELXL modules.⁴² The phenyl ring of the benzyl group in structure 3k is disordered over two positions (A and B) due to rotation around the C_{sp³}–C_{ar} bond. The restrictions on the bond lengths in the disordered fragment were applied (C_{ar}–C_{ar} = 1.39 Å). The hydrogen atoms were placed in their ideal positions and refined by "riding" model with $U_{\text{iso}} = nU_{\text{eq}}$ of the carrier atom ($n = 1.5$ for methyl groups and $n = 1.2$ for other hydrogen atoms). The crystallographic data and experimental parameters are listed in Table S1 in Supplementary section. Deposition Numbers CCDC 2416411 for structure 3b and CCDC 2416347 for structure 3k contain the supplementary crystallographic data for this paper. These data can be obtained free of charge by the joint Cambridge Crystallographic Data Centre and Fachinformationszentrum Karlsruhe Access Structures service <http://www.ccdc.cam.ac.uk/structures>.

Molecular docking setup

The molecular docking setting up was carried out with the AutoDock Tools (ADT) software, version 1.5.7.⁴³ The addition of hydrogen, the calculation of the Gasteiger charges of the receptor, and ligands were also performed using the ADT software. Molecular docking calculations were performed with the AutoDock Vina 1.1.2 software.^{43,44} The 3D X-ray structure of *Paenibacillus polymyxa* β -glucosidase B (BglB, PDB 2O9R),⁴⁵ *Raucaffricine* β -glucosidase (rBG, PDB 4A3Y),⁴⁶ *Thermotoga maritima* β -glucosidase (TmGH1, PDB 1OD0),⁴⁷ and human cytosolic β -glucosidase (hCBG, PDB 2JFE)⁴⁸ were downloaded from the RCSB Protein Data Bank. The calculations details were described in details elsewhere.^{26,39}

Results and discussion

Absorption and fluorescence spectra in solutions

Research into the electronic transitions of flavonol molecules, conducted using both semi-empirical methods and density functional theory (DFT), has revealed that broad absorption bands in the 340–380 nm and 240–270 nm ranges result from intense electronic transitions occurring primarily between molecular orbitals located on the chromone fragment of these molecules.⁴⁹ In this case, the side benzene ring can affect the

^a λ_{abs} , ν_{abs} – wavelength and wave number of the electronic transition, f – transition oscillator strength, C.I. – configuration composition of the transition, types of transitions – CHR – local, located predominantly on the chromone fragment, CT – transition with interfragment charge transfer, FL – transition localized on the molecule as a whole, $n \rightarrow \pi^*$ – forbidden $n\pi^*$ transition. ICT – value of interfragment charge transfer during the $S_0 \rightarrow S_1$ transition.

electron density distribution within the chromone fragment, which may result in a shift in the absorption bands. Therefore, according to chromophore theory, the side benzene ring operates as an auxochrome of a complex structure. Electronic transitions involving inter-fragmental charge transfer between the side benzene ring and the chromone part of the molecule typically occur in the short-wavelength region of the spectrum. However, when a strong electron donor, such as $-\text{N}(\text{CH}_3)_2$, or a strong electron acceptor, such as $-\text{NO}_2$, is present in the side ring, the electronic transition shifts to the long-wavelength region. This transition can occur either from the molecular orbitals localized on the benzene ring to the orbitals of the chromone fragment, or *vice versa*. The presence of a charge transfer transition is manifested by the appearance of a new long-wavelength absorption band in the range of 400–430 nm.¹² Table 2 summarizes the calculated absorption and fluorescence parameters of flavonols 3a–f in water.

The molecular orbitals of unsubstituted flavonol, as well as its monosubstituted derivatives that have hydroxyl groups in the C3' and C4' positions, are illustrated in Fig. 1. Meanwhile, the disubstituted derivative, 3',4'-dihydroxyflavonol, is also included in this analysis. Fig. 2 presents a diagram showing the relative energies of these molecular orbitals. Additionally, Table 2 provides details on the theoretical parameters of long-wavelength transitions observed in the spectra of these compounds. The analysis of configurational interaction reveals that the long-wavelength intense transitions of all flavonols can be characterized by a transition between the highest occupied molecular orbital (MO) ϕ_1 and the lowest vacant molecular orbital ϕ_1' . The MO ϕ_1 is delocalized between the chromone and the side phenyl fragment. However, as the torsion angle between these fragments increases, the localization of MO ϕ_1 increasingly favors the chromone fragment. In contrast, the vacant MO ϕ_1' is primarily localized on the chromone fragment.

Therefore, it can be concluded that the long-wavelength electronic transition generally exhibits a “chromone” nature (CHR).

This conclusion is supported by the relatively low values of interfragment charge transfer during the transition from the ground state to the Frank–Condon excited state S_1 , which are approximately 0.1–0.2 electronic charges (e^-) only. These low values suggest that the side phenyl ring does not significantly participate in the excitation process.

The Table 2 illustrates that increasing the number of substituents in the phenyl side ring results in a decrease in $S_0 \rightarrow S_1$ transition energy, *i.e.* to a bathochromic shift of the corresponding absorption band from 350 nm to 370 nm approximately. Adding a substituent at position C4' enhances the transition oscillator strength f , which in turn increases the intensity of the associated absorption band. Conversely, introducing a substituent at position C3' has the opposite effect, reducing the intensity of the absorption band.

DFT calculations of the electronic spectrum for the compound featuring an OH group at the C3' position reveal an additional long-wavelength band in the ~ 330 nm range. This band results from an electronic transition between the ϕ_2 orbital, which is localized on the side phenyl ring, and the ϕ_1' orbital, which is localized on the chromone fragment. This transition is associated with significant inter-fragment charge transfer (ICT). In the spectra of other compounds, similar transitions are observed in the shorter wavelength region of 285–290 nm (see Table 2). This phenomenon occurs due to an increase in the energy of the corresponding occupied molecular orbital when a substituent is introduced at the C3' position. In Fig. 2, the energies of the molecular orbitals localized on the side phenyl ring are highlighted in red. In the 305–310 nm spectrum range, all compounds have a forbidden $n\pi^*$ transition from the n -orbital ϕ_4 to the orbital ϕ_1' . The short-wave intense band ranging from 280 to 315 nm in all spectra is

Fig. 1 Frontier molecular orbitals of flavonol, and substituted flavonol with 3'-OH, 4'-OH, and 3',4'-OH.

attributed to the electronic transition $\phi_2 \rightarrow \phi_1'$ (with $\phi_3 \rightarrow \phi_1'$ occurring in the compound substituted at the C3' position). As illustrated in Fig. 1, the ϕ_2 orbital is delocalized across both fragments of the flavonol molecule. Therefore, the transition from ϕ_2 to ϕ_1' is not localized and can be understood as the excitation of the molecule as a whole. It should be noted that

the results from the DFT method correlate well with semi-empirical methods.⁴⁹

The impact of the side phenyl ring on the chromone fragment arises from both the electronic effects of its substituents and the extent of their electronic conjugation governed by the torsion angle between the planes of the both fragments. The

Fig. 2 Influence of substituents' positions on MO energies in flavonols obtained using the b3lyp/cc-pVDZ level of theory (see Table 2 for more details).

conformations of flavonol molecules in the gas phase, as well as in dichloromethane and acetonitrile, were investigated by modeling the potential energy curves associated with the rotation of the side ring relative to the plane of the chromone fragment. This rotation was analyzed over an angle range from -30° to 150° for 3'-hydroxy-, 4'-hydroxy-, and 3',4'-dihydroxyflavonols. As illustrated in Fig. 3, regardless of the substituent's position, the minimum potential energy occurs at angles between -10° and 10° . This observation indicates that over 97% of flavonol molecules are planar in both solutions and the gas phase. Furthermore, the calculations reveal that an increase in the polarity of the medium results in a decrease in the rotation barrier by approximately 0.6 to 0.7 kcal mol $^{-1}$.

The influence of electronic effects from substituents is quantified by the Hammett constants σ_{para} and σ_{meta} . However, since multiple substituents can simultaneously occupy the para and meta positions in the side ring, and considering the

^a σ_{para} – Hammett constants for R-oxyphenyl fragments, λ_{abs} – absorption band maxima in nm scale, ν_{abs} – absorption band maxima in cm $^{-1}$ scale, $\Delta\nu_{\text{abs}}$ – shifts of absorption band maxima on going from dichloromethane to acetonitrile. ^b Spectral data for unsubstituted flavonol **3** were taken from ref. 50. The data for nonpolar medium are shown for chloroform.

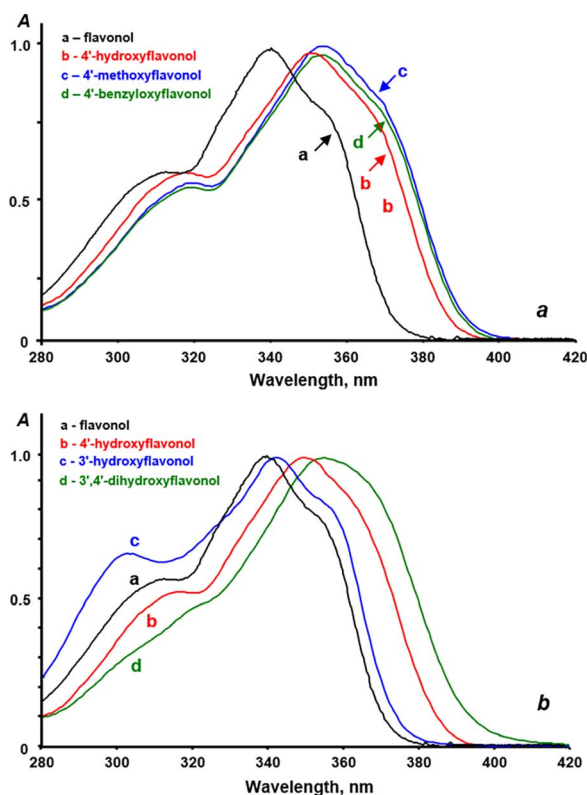

Fig. 4 Normalized absorption spectra of the studied flavonols in dichloromethane. a – different substituents in the same position of the side benzene ring, b – the same substituents in different positions of the side benzene ring. Concentrations of flavonols were in a range of $1\text{--}5 \cdot 10^{-5}$ M.

dampening effect of the aromatic π -system, we calculated the overall σ_{para} constants for various RO-phenyl substituents using the web tool outlined in the article.⁵¹ The calculated σ_{para} values are presented in Table 3. It is important to note that these σ_{para} values are notably low, indicating a very weak influence of the substituents in the side benzene ring on the electronic structure of the chromone moiety of the molecules.

A comparison of the σ_{para} constants with the positions of the long-wavelength absorption bands in the experimental spectra of flavonols revealed no correlation between them.

This indicates that substituents do not have a significant impact on the spectral parameters of flavonols. For example, substituting a hydroxy group with either a methoxy group or a benzyloxy group in the same position on the aromatic ring does not cause any shift in the absorption band (see Table 3 and Fig. 4a). Additionally, no shifts in the band position were observed with any combinations of substituents in 3',4'-disubstituted flavonols.

More significant differences in the absorption band parameters are observed depending on the positions of the substituents in the benzene ring (see Fig. 4b). For 3'-R-hydroxyflavonols in dichloromethane, regardless of the type of substituents, the absorption maximum falls within the range of 345–346 nm ($28\,900\text{--}28\,985\text{ cm}^{-1}$). The σ_{para} constants for these compounds have positive values of +0.01 to +0.03, indicating a very weak

electron-withdrawing effect of the benzene ring on the chromone fragment. In contrast, 4'-R-oxyflavonols and 3',4'-di-R-hydroxyflavonols exhibit long-wavelength band maxima in approximately similar range: at 351–355 nm ($28\,170\text{--}28\,490\text{ cm}^{-1}$) and 353–361 nm ($27\,700\text{--}28\,330\text{ cm}^{-1}$), respectively. The corresponding σ_{para} constants for these compounds range from -0.01 to -0.05 , suggesting that the benzene ring demonstrates weakly expressed electron-releasing properties. When going to a more polar environment, such as acetonitrile, a slight hypsochromic shift of the absorption bands from 80 to 500 cm^{-1} is observed (see Table 3). Additionally, the effect of substituent position is even less pronounced in acetonitrile.

The σ_{para} values indicate that substituents on the side benzene ring have a very weak effect on the spectral properties of flavonols. In contrast, the introduction of 4'-diethylamino- and 4'-nitro substituents into the side ring results in significant changes to the absorption spectra. In these latter cases, the σ_{para} values are tens of times greater, measuring -0.146 and $+0.372$, respectively. Natural flavonols commonly contain hydroxy and various alkoxy groups, which typically have low σ_{para} values. Therefore, it can be assumed that natural flavonols with a similar structure in the chromone moiety of their molecules will exhibit approximately the same absorption spectra, regardless of the type or location of substituents in the side phenolic ring.

Due to the ESIPT process, the fluorescence spectra of flavonols can exhibit two distinct fluorescence bands. The first is a short-wavelength emission band corresponding to the excited form of the original flavonol (N^*), and the second is a long-wavelength emission band from the phototautomer (T^*), which is formed by the transfer of a proton from the 3-hydroxy group to the carbonyl group of the chromone fragment. Proton transfer is typically a very rapid and irreversible process, resulting in the fluorescence spectrum usually displaying only

^a λ_{fl} , ν_{fl} – these designations are given in Table 2, $\Delta\nu_{\text{St}}$ – Stokes shifts of fluorescence, cm^{-1} . ^b Spectral data for unsubstituted flavonol were taken from ref. 50 data for nonpolar medium are shown for chloroform.

one long-wavelength band of the phototautomer (T^*). However, as the polarity of the medium increases, the activation barrier for the proton transfer reaction also increases. Consequently, a band corresponding to the N^* form may appear in the fluorescence spectra. In proton-donating solvents or when proton-donating impurities are present, flavonols can form intermolecular hydrogen bonds. This leads to suppressing the excited-state intramolecular proton transfer (ESIPT) and results in the fluorescence of the N^* form. Additionally, substituents on the side ring of flavonols can influence the dynamics of phototautomerization. Specifically, introducing an electron-releasing group at the C4' position may decrease the acidity of the 3-hydroxy group in the chromone ring and slow down ESIPT, which can lead to the emergence of two-band fluorescence.

The experimental fluorescence spectra of all the studied flavonols exhibited a single emission band. This observed emission band is attributed to the T^* phototautomer, as indicated by the high Stokes shift values in the range of 8900–10500 cm^{-1} (see Table 4). A trace amount of fluorescence from the N^* form can be detected in the short-wavelength region of the spectra. However, this may be attributed to water impurities that were adsorbed by acetonitrile during the experiment, as well as the formation of trace amounts of flavonol hydrates, which may not undergo proton phototransfer. Considering the low σ_{para} values and the spectral parameters outlined in Table 3, we can conclude that the fluorescence spectra of natural flavonols in aprotic solvents will be single-band, regardless of the nature and position of the substituents in the side benzene ring.

The effects of the nature and position of these substituents are illustrated in Fig. 5a and b, while the quantitative parameters of the emission bands are provided in Table 3.

The analysis of the data in Table 3 indicates that the nature and position of the substituents in the side benzene ring have a lesser impact on the position of the T^* emission band compared to the position of the absorption bands. Specifically, the average emission band maxima for 3'-R-oxy-, 4'-R-oxy-, and 3',4'-R-dioxyflavonols are 525 ± 2 nm, 529 ± 1 nm, and 533 ± 4 nm, respectively. The shifts of the bands when changing the position of the substituent range from 135 to 145 cm^{-1} on the energy scale, which indicates that these shifts are relatively insignificant.

The energy costs involved in rearranging the geometry of molecules and their solvate shell is characterized by the Stokes shifts of fluorescence ($\Delta\nu_{\text{St}}$). For the flavonols studied in dichloromethane, the values of $\Delta\nu_{\text{St}}$ range from 9850 to 9925 cm^{-1} for 3'-R-hydroxyflavonols, 9265 to 9550 cm^{-1} for 4'-R-hydroxyflavonols, and 8940 to 9425 cm^{-1} for 3',4'-R-dihydroxyflavonols. Notably, the lowest Stokes shift values are observed in flavonols that lack hydroxyl groups. Considering the similar mechanism and kinetics of excited-state intramolecular proton transfer (ESIPT), as well as the larger $\Delta\nu_{\text{St}}$ values for hydroxyl-containing flavonols and the planar geometry of molecules in both the initial and phototautomeric forms (T^*), we can conclude that the differences in Stokes shifts arise from the structural characteristics of the solvation shell in the ground state and its subsequent rearrangement during phototautomerization.

The changes in solvent polarity on going from dichloromethane to acetonitrile do not significantly affect the position of the phototautomer emission bands. The observed shifts in the bands are multidirectional, do not exceed a few nanometers, and are statistically insignificant. The Stokes shifts of fluorescence for 3'-R-hydroxyflavonols, 4'-R-hydroxyflavonols, and 3',4'-R-dihydroxyflavonols in acetonitrile are within the ranges of 10 190–10500 cm^{-1} , 9775–10290 cm^{-1} , and 9150–9665 cm^{-1} , respectively. Thus, $\Delta\nu_{\text{St}}$ values of flavonols in more polar acetonitrile are correspondingly 460, 625, and 225 cm^{-1} higher than those in less polar dichloromethane. A comparison of the spectral characteristics of the absorption and fluorescence bands indicates that the increase in $\Delta\nu_{\text{St}}$ is due to a hypsochromic shift of the absorption bands when going from dichloromethane to acetonitrile solutions. This suggests additional energy costs are associated with the relaxation of the solvate shell of flavonols upon excitation in polar media.

Fluorescence spectra in the solid state

To investigate the spectral properties of flavonols in the solid phase, we grew crystals of the compounds we were studying and recorded their fluorescence spectra. Since recording the absorption spectra of the crystals was not possible, we obtained fluorescence excitation spectra for each compound instead. The shape of these fluorescence excitation spectra closely resembles that of the corresponding absorption spectra, enabling us to

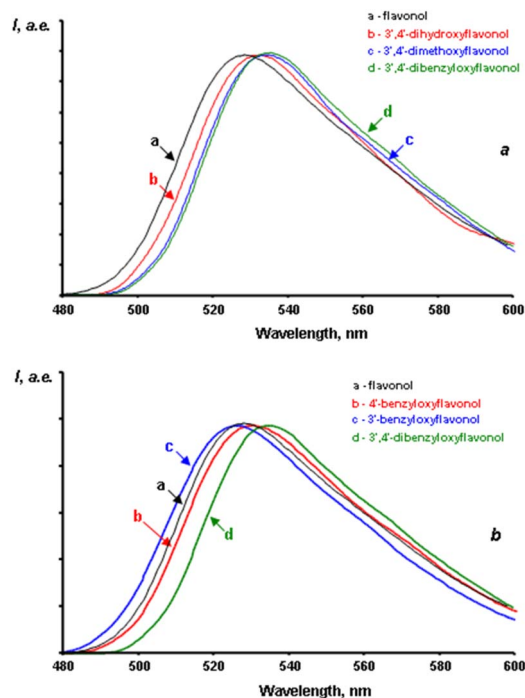

Fig. 5 Fluorescence spectra of studied flavonols in dichloromethane. a – different substituents in the same position of the side benzene ring, b – the same substituents in different positions of the side benzene ring. Concentrations of flavonols were in a range of $1\text{--}5 \cdot 10^{-5}$ M.

^a λ_{ex} , ν_{ex} – positions of long-wavelength excitation bands in nm and cm^{-1} ; λ_{N} , ν_{N} , λ_{T} , ν_{T} – positions of emission bands of N* and T* forms in nm and cm^{-1} ; $\Delta\nu_{\text{St,N}}$ and $\Delta\nu_{\text{St,T}}$ – Stokes shifts of fluorescence of N* and T* forms in cm^{-1} calculated relatively long-wavelength excitation bands: $\Delta\nu_{\text{St,N}} = \nu_{\text{exc}} - \nu_{\text{N}}$ and $\Delta\nu_{\text{St,T}} = \nu_{\text{exc}} - \nu_{\text{T}}$; $I_{\text{N}}/I_{\text{T}}$ – ratio of intensities of forms N* and T*. ^b Spectral data for unsubstituted flavonol were taken from ref. 50 data for nonpolar medium are shown for chloroform.

assess the light absorption characteristics of flavonols in their solid state.

Fluorescence excitation spectra were measured by assessing the luminescence intensity at 450 nm and 550 nm, corresponding to the emission regions of the N* and T* forms, respectively. The refined positions of the maxima of the long-wavelength band in the excitation spectra ($\lambda_{\text{max}}^{\text{ex}}/\nu_{\text{max}}^{\text{ex}}$) were determined through double differentiation of the spectral curves. The differences in maxima positions in the spectra measured at 450 nm and 550 nm did not exceed 3 nm; therefore, averaged values of $\lambda_{\text{max}}^{\text{ex}}/\nu_{\text{max}}^{\text{ex}}$ were utilized for further

analysis of the obtained data. The spectral characteristics of flavonols in the solid state are presented in Table 5.

The data presented in the Table 5 indicate that the positions of the fluorescence excitation bands in the solid phase do not correspond with the positions of the absorption bands in flavonol solutions, nor do they align with the Hammett constants of the side ring. When going from the less polar solvent dichloromethane to the more polar solvent acetonitrile, the positions of absorption band maxima shift hypsochromically by an average of 415 cm^{-1} . In contrast, moving to the crystalline phase results in a bathochromic shift of the bands by

Fig. 6 Molecular structure of compounds 3b (on the left) and 3k (on the right) according to the X-ray diffraction data. Thermal ellipsoids are shown at 50% probability level.

an average of 730 cm^{-1} , which suggests a decrease in the environmental polarity. Additionally, flavonols in the crystalline state exhibit a smaller variation in the bands' positions.

To understand how substituents on the side benzene ring of flavonols influence their spectral properties, X-ray structural analysis was conducted on compounds **3b** and **3k**. The structures and geometries of the substances studied, as obtained from X-ray diffraction, are illustrated in Fig. 6. It is important to note that the "crystallographic" numbering of atoms, assigned during structure resolution using the OLEX2 package, does not align with the atom numbering typically used for flavonols. Therefore, when referencing the "crystallographic" atom numbers below, an asterisk will be used to indicate them.

The presence of a phenyl substituent at the C9* atom in molecules **3b** and **3k** (Fig. 6) suggests conjugation between the π -systems of the chromone fragment and the side benzene ring. The X-ray analysis revealed that, in contrast to their geometry in solution or the gas phase, flavonols in a crystalline state are non-planar molecules. Thus, in molecules **3b** and **3k**, these fragments are rotated relative to each other (torsion angle C8*-C9*-C10*-C11* in Fig. 6) by $12.3(3)^\circ$ in molecule **3b** and by $-17.3(4)^\circ$ in molecule **3k**, and the length of the C9*-C10* bond ($1.468(2)\text{ \AA}$ in molecule **3b** and $1.463(3)\text{ \AA}$ in molecule **3k**) is comparable to the average length of the $C_{sp^2}-C_{ar}$ bond in conjugated systems 1.470 \AA .⁵²

The non-planarity of flavonol molecules in the solid state, *i.e.* the presence of some non-zero dihedral angles between the molecular fragments additionally diminishes the influence of substituents on the side ring regarding the electron density distribution in the chromone part of the molecule. Thus, the effect of substituents on the spectral properties of flavonols occurs only indirectly, mediated by conformational effects and the polarity of the surrounding environment. The latter is influenced by the parameters of the crystal lattice, which can in turn be affected by the volumetric characteristics and positions of the substituents.

Unlike the fluorescence spectra of flavonol solutions, which show only one emission band from the T* phototautomer, the spectra of flavonols in the solid state exhibit two emission bands (Fig. 7).

Fig. 7 Fluorescence spectra of flavonols in the solid state.

The short-wavelength fluorescence bands of the N* form in most flavonols typically range from 450 to 460 nm (approximately $22\,200\text{--}21\,700\text{ cm}^{-1}$). However, in compounds **3d**, **3e**, and **3j**, these bands are slightly shifted toward the long-wavelength region. It is important to note the large Stokes shifts of fluorescence, which range from 4800 to 6900 cm^{-1} . This range is approximately 1500 to 2500 cm^{-1} greater than that observed in most fluorophores. This discrepancy likely results from significant energy costs associated with the structural relaxation of the excited molecule within a rigid crystal lattice.

The fluorescence bands of the T* form are centered between 540 and 560 nm (corresponding to $18\,550\text{--}17\,850\text{ cm}^{-1}$). These bands are shifted by 20 to 30 nm toward the long-wavelength region of the spectrum compared to the fluorescence bands of the same form in the solutions. In the solid state, the Stokes shifts of the fluorescence of the flavonol phototautomer are smaller than those in the solutions, measuring between 8800 and 9730 cm^{-1} . This suggests the absence of a significant structural relaxation of the phototautomer in the excited state.

No dependence was found between the positions of the N* and T* bands in the fluorescence spectra of crystalline flavonols and the nature or position of the substituents in the side ring.

The appearance of the short-wavelength N* emission band evidences that the intramolecular proton transfer is partially suppressed. The side ring substituents have weak electronic effects, and the non-planar geometry of the molecules suggests that the side rings have a minimal impact on proton transfer kinetics. Another factor contributing to the reduced efficiency of the excited-state intramolecular proton transfer is the weakening of the intramolecular hydrogen bond necessary for the proton transfer between the carbonyl group and the 3-hydroxy group of chromone.

As illustrated in Fig. 8, the hydrogen atoms of the 3-hydroxy group form bifurcated hydrogen bonds. According to Etter's rules,^{53,54} the formation of intramolecular hydrogen bonds is preferred over intermolecular hydrogen bonds. However, the hydrogen bond that closes the five-membered ring is not sufficiently effective. This likely leads to the hydroxyl group in all three structures acting as a proton donor in two hydrogen bonds simultaneously: the intramolecular $O_3^*-\text{H}\cdots O_2^*$ and the intermolecular $O_3^*-\text{H}\cdots O_2^*$. The O_2^* atom, in turn, serves as a proton acceptor in both hydrogen bonds.

The nature of the primary structural motif formed by the intermolecular hydrogen bonds varies. In structure **3b**, hydrogen-bonded chains are formed, while in structures **3c** and **3k**, centrosymmetric hydrogen-bonded dimers are established (see Fig. 8). It is important to note that the formation of bifurcated hydrogen bonds weakens each bond, as demonstrated by their characteristics (refer to Table 6).

Since the formation of multi-center hydrogen bonds weakens the intramolecular hydrogen-bond component, it leads to a decrease in the rate of phototautomerization. Consequently, the rate of the proton transfer becomes comparable to the rate of emission of the original form N*, which results in the appearance of the corresponding short-wavelength band N* in the spectra.

Fig. 8 Crystalline structure of 4'-methoxy (**3b**) and 3'-benzyloxy (**3k**) flavonols. Intramolecular and intermolecular hydrogen bonds are shown with green dashed lines.

Table 6 Geometric characteristics of hydrogen bonds in structures **3b** and **3k**

		Geometric characteristics		
Hydrogen bond	Symmetry operation	H⋯O, Å	O⋯O, Å	O–H⋯O, deg
Structure 3b				
O3*–H⋯O2*		2.23	2.677(2)	113.30
O3*–H⋯O2'*	1 – x, 0.5 + y, 0.5 – z	1.98	2.753(2)	153.6
Structure 3k				
O3*–H⋯O2*		2.27	2.712(3)	113.5
O3*–H⋯O2'*	–x, –y, 1 – z	2.01	2.751(3)	146.0

The fluorescence intensity ratio of the initial form (N*) to the phototautomer (T*), represented as I_N/I_T , indicates that for most compounds, the emission intensity of form N* is greater than that of form T*. In several flavonols, the intensity I_N can exceed I_T by 10–20%. However, most compounds show low ESIPT efficiency with the luminescence intensity of form N* surpassing that of form T* by 1.5 to 2.5 times. An analysis of the I_N/I_T values reveals that the ratio of forms N* and T* in the excited state does not depend on the position and nature of the substituents. Nonetheless, a significant slowdown in ESIPT is primarily observed in flavonols with bulky benzyl substituents. This suggests that the spectral properties of these compounds must be determined by the characteristics of their crystal.

Binding interactions of flavonols with β -glucosidase

Fluorescent flavonols serve as promising molecular probes for investigating protein-ligand interactions, with the goal of understanding the mechanisms of enzyme action.^{55,56} They also provide a theoretical foundation for the design and discovery of new regulators of enzymatic activity.^{55,57,58} Recently, we demonstrated that the ESIPT fluorescence of flavonols is highly sensitive to binding interactions with proteins, making it an

effective tool for probing protein structure and their hydrophobic pockets.^{59,60} Furthermore, incorporating bulky alkyl and benzoyl groups into the 2-phenyl ring of flavonols increases their hydrophobicity and enhances the binding affinity to β -glucosidase, allowing for the inhibition of the enzyme's activity.²⁶

In this study, we aimed to investigate the influence of C3'- and C4'-substitutions in flavonols on their protein binding affinity and selectivity. We examined the fluorescence properties of flavonols when interacting with β -glucosidase. Fig. 9 displays the results of fluorescence titration of flavonols **3k** and **3l** by varying concentrations of β -glucosidase in a phosphate buffer at pH 6.86. Despite their common use in biomedical applications, flavonols have low solubility in water.⁶¹ To address this issue, we dissolved them in the buffer by adding small aliquots of their DMSO stock solution. To explore the interaction between flavonols and the enzyme, we followed a fluorescence titration protocol similar to the one used in our recent study.²⁶ In summary, during the titration, we maintained the concentration of flavonols at approximately $1\text{--}2 \times 10^{-5}$ M, while gradually varying the concentration of glucosidase from 0 to 9.5×10^{-4} M.

As shown in Fig. 9, the fluorescence intensity of both flavonols **3k** and **3l** increases with higher concentrations of β -glucosidase. This phenomenon, which has also been observed with other flavonols, is attributed to a protein-induced "turn-on" effect.^{26,39,58,59,62} The increase in fluorescence can be explained by the reduction of water-induced fluorescence quenching, which occurs as the probes bind to and penetrate deeper into the water-free hydrophobic regions of biomacromolecules.^{6,63} In addition to the significant "turn-on" effect observed, there is also a noticeable redistribution of the normal-to-phototautomer emission intensity. Specifically, the contribution of the normal form, represented by the short-wavelength band around 450 nm, gradually increases. This dual-band redistribution is more prominent in the case of

Fig. 9 Fluorescence titration of flavonols **3k** (a) and **3l** (b) with β -glucosidase. The flavonol fluorescence was measured in the phosphate buffer pH 6.86 at 298 K after excitation at 380 nm. The arrows indicate the flavonol spectra: (1) in the absence of β -glucosidase, (2) after adding the first β -glucosidase aliquot, (3) in the presence of maximal concentration of β -glucosidase. The flavonol concentration of $2.3 \cdot 10^{-5}$ M (a, b) was constant, whereas the β -glucosidase concentration was varied in a range from $1.1 \cdot 10^{-5}$ up to $9.5 \cdot 10^{-4}$ M (a) and from $2.2 \cdot 10^{-5}$ up to $8.8 \cdot 10^{-4}$ M (b).

flavonol **3l**, indicating a possible alteration in its binding mode to the β -glucosidase protein (see Fig. 9b).

The strong fluorescence of the normal form suggests that the ESIPT process is somewhat inhibited in the protein-bound state of flavonols **3k** and **3l**. Several factors could explain this, including: (i) the formation of intermolecular hydrogen bonds with protein residues, or (ii) the disruption of the intramolecular hydrogen bond between the 3-OH group and the 4O carbonyl oxygen due to steric constraints within the protein-binding pocket. Additionally, it is possible that both mechanisms contribute to the ESIPT-sensitive behavior of the flavonols. This implies that even small modifications in the peripheral side ring of the chromone moiety could significantly influence ligand-protein interactions, including their strength and selectivity.

ADMET properties

The physicochemical properties of molecular probes influence their water solubility, lipophilicity, and binding affinity to organized hydrophobic environments, such as micelles, lipid membranes, plasma proteins and other biomacromolecules. In the context of *in vitro* and in-cell studies, a proper balance of these properties is crucial for governing the adsorption, distribution, metabolism, and pharmacokinetics of flavonols used as ESIPT probes. Therefore, a thorough understanding of these properties, referred to as ADMET (Absorption, Distribution, Metabolism, Excretion, and Toxicity), along with their measurement and prediction, is essential for successful probe design and development.⁶⁴

Probe's lipophilicity affects its permeability across cell membranes, the partitioning and distribution of a drug-like molecule, as well as its metabolism and renal excretion.⁶⁵ Our fluorescence titration experiments shown in Fig. 9 demonstrated that flavonol binding to the protein was primarily driven by the hydrophobic effect because of their high lipophilicity. Therefore, we first tried to see if there is some correlations

between spectral changes seen in Fig. 9 and lipophilicity of the studied flavonols.

Lipophilicity is defined as the logarithm of the octanol–water partition coefficient ($\log P_{o/w}$) that reflects the ability of a molecule to dissolve in the lipophilic environment, such as a lipid membrane.

Table 7 summarizes calculated consensus $\log P$ for model flavonol **3** and studied flavonols **3a–m**. Table 7 illustrates that the gradual introduction of methoxy and benzoyl groups into the 2-phenyl ring increases the $\log P_{o/w}$ value from 2.84 for the unsubstituted flavonol to as high as 5.87 for the compound **3m**. It is also noteworthy that empirical *in silico* predictions of $\log P_{o/w}$ parameters are not sensitive to the specific positions of substitutions. For instance, both **3j** and **3l** were predicted to have the same $\log P_{o/w}$ value of 4.33. To thoroughly investigate the molecular-level details of how variations in the C3' and C4'-substituents fine-tune protein-ligand binding interactions, computational tools, such as molecular docking, that account for the implicit structure of proteins should be utilized.

Molecular docking calculations

Due to the unavailability of the high-resolution 3D structure of the β -glucosidase from commercial almonds used in our experimental studies,⁶⁶ we turned to X-ray structures of β -glucosidases from other sources. The β -glucosidase family includes a variety of enzymes that exhibit different activities and are widely distributed across many living organisms.⁶⁷ These enzymes share the common ability to hydrolyze β -glucosidic linkages found in disaccharides, oligosaccharides, and conjugated saccharides.

Fig. 10 illustrates the X-ray structure of the β -glucosidase from *Thermotoga maritima* (TmGH1). Although there are some variations in the primary structure at the peripheral regions of the protein, all enzymes within the glucosidase family exhibit a high sequence identity of over 90%. The main common features of these enzymes include: (i) the presence of a deep

hydrophobic pocket that can accommodate substrate molecules during cellulolytic hydrolysis (Fig. 10a), and (ii) a catalytic active site composed of two glutamate (Glu) residues situated in close proximity to each other (see Fig. 10a and b).

For our molecular docking analysis of flavonol–glucosidase interactions, we selected β-glucosidases from four different sources: *Paenibacillus polymyxa* β-glucosidase B (BglB),⁴⁵ *Raucaffricine* β-glucosidase (rBG),⁴⁶ *Thermotoga maritima* β-glucosidase (TmGH1),⁴⁷ and human cytosolic β-glucosidase (hCBG).⁴⁸ The X-ray 3D structures of these proteins have been well resolved, so that some of them already used as receptor models for molecular docking calculations.^{26,39,62,68–70}

The structural and energetic characteristics of the interactions between flavonols **3k** and **3l**, and β-glucosidases were

analyzed using molecular docking calculations, which are summarized in Table 8.

The results indicate that all examined flavonols exhibit strong binding affinities, with values exceeding −8.5 kcal mol⁻¹. Furthermore, flavonols can penetrate deeply into the central cavity of β-glucosidase and bind closely to the catalytic glutamic acid (Glu) residues.

Examples of binding modes for flavonols are illustrated in Fig. 11, specifically for β-glucosidase TmGH1. Molecular docking studies indicate that the binding affinity of compounds **3k** and **3l** to β-glucosidase depends on the specific characteristics of the peripheral substituents located at the C3'- and C4'-positions of the flavonol's phenyl ring.

In the case of flavonol **3k**, it binds deeper into the enzyme pocket, with the 3OH-chromone moiety favoring a position

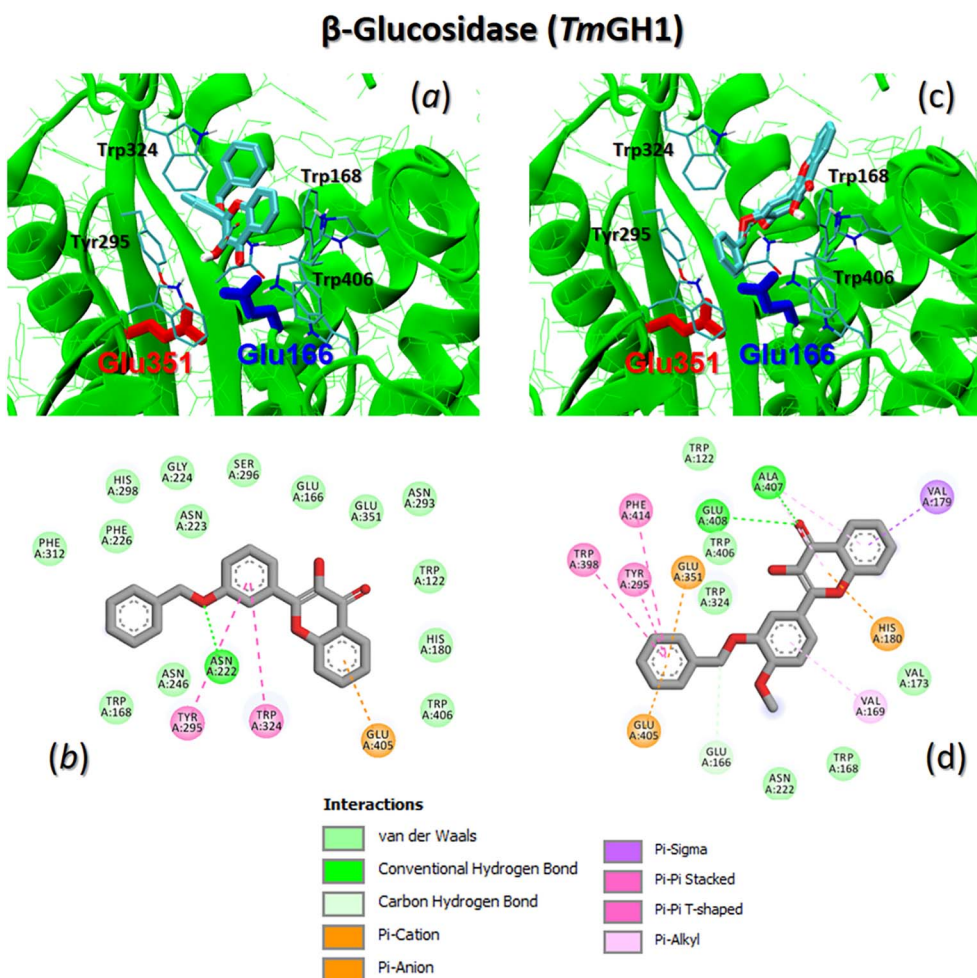

Fig. 11 The best binding mode of flavonols **3k** (a and b) and **3l** (c and d) to β -glucosidase TmGH1 (PDB 1OD0). The catalytic residues Glu166 and Glu351 are shown as color-coded sticks. Some key enzyme interacting residues are also shown. (b and d) 2D interaction maps of selected flavonols with key protein residues.

close to the catalytic residue Glu166. The bulky 3'-benzyl ring protrudes outward from the enzyme pocket (see Fig. 11a). In contrast, the introduction of an additional 4'-methoxy group results in a reversal of the binding mode. For flavonol 3l, the 2-phenyl ring, featuring the bulky 3'-benzyl and 4'-methoxy groups, occupies the catalytic pocket, displacing the 3OH-chromone moiety outwards (see Fig. 11c).

Fig. 11b and d illustrate 2D interaction maps of flavonols with β -glucosidase TmGH1. Flavonol **3k** binds to TmGH1 through non-covalent interactions, including π - π stacking of the 2-phenyl ring with TYR295 and TRP324. It also involves short-range π -anion interactions between the aromatic ring of the chromone and GLU405, as well as hydrogen bonding between the 3'-benzyl oxygen atom and ASN222 (Fig. 11b). In contrast, flavonol 3l exhibits much more complex interaction patterns. The major contributions to its binding include classical π - π stacking or π - π T-shaped stacking of the 3'-benzyl ring with TYR295, TRP298, and PHE414. Additionally, there are π -anion interactions of the 3'-benzyl ring with GLU405 and catalytic GLU351, along with hydrogen bonding of the 2O carbonyl oxygen atom with ALA407 and GLU408 (Fig. 11d).

Summary and perspectives

Natural flavonols, including compounds like quercetin, morin, fisetin, and galangin, are among the most abundant classes of metabolic polyphenols. They exhibit a wide range of pharmacological activities beneficial to human health.^{1,2} Many flavonols also display unique dual ESIPT-emission fluorescence, which makes them sensitive to changes in their microenvironment.^{6,7} This property offers exciting opportunities for sensing and detecting metal ions, anions, small ligands, and biomacromolecules.^{3,24,58,71} However, the diverse structures of flavonols—characterized by variations in the number and position of hydroxyl groups, as well as various chemical modifications—complicate the relationship between their structure and fluorescence.^{23,72} As a result, using them as fluorescent probes can often be challenging.⁵⁸

This study aims to clarify the influence of hydroxy, methoxy, and benzyl groups at the C3' and C4' positions of the 2-phenyl side ring of flavonols. We focus on examining their ESIPT fluorescence, crystal packing, physicochemical properties, and ADMET characteristics. A series of flavonols were synthesized, and their structures were characterized using NMR and MS analysis. We systematically investigated the fluorescence properties of the synthesized flavonols in aprotic solvents, analyzing the relationships between their structures and properties. Our main findings suggest that the nature and position of substituent groups in flavonols significantly influence their crystal packing in the solid state. We discovered that the molecular arrangement in the crystal lattice could be affected by intra- and intermolecular hydrogen bonding ratio, which in turn affects the ESIPT dual-band ratio. Furthermore, by employing fluorescence titration and molecular docking calculations, we explored how the introduction of a bulky benzyl moiety and the alteration of its position between C3'- and C4'- can impact the binding interactions of flavonols with β -glucosidases. We

believe our findings shed light on the structure–fluorescence relationship in flavonols and open up new possibilities for the design of innovative flavonol-based probes.
