Heterometal doping and the introduction of surface ligands drastically alter the optical and photophysical properties of gold-based superatoms by modulating their electronic structures and the excited state dynamics. In this study, we investigate how the structures and the optical properties of an Ir@Au₁₂ superatom capped by a diphosphine ligand, bis[benzo[*b*]phosphindole]ethane (bbpe), in which the rotation of the phenyl groups is prohibited, differ from those capped by the conventional diphosphine ligands, such as 1,2-bis(diphenylphosphino)ethane (dppe) and bis(diphenylphosphino)methane (dppm). The co-reduction of Ir(III)- and Au(I)-precursors under mild reaction conditions yielded homoleptically capped [IrAu₁₂(bbpe)₆]³⁺ clusters (IrAu₁₂-b) as the primary product. Single crystal X-ray diffraction analysis of IrAu₁₂-b revealed the formation of a nearly perfect icosahedral Ir@Au₁₂ superatomic core, in which the central Ir atom is equidistant from each vertex Au atom. The energy gap between occupied 1P and unoccupied 1D superatomic orbitals of IrAu₁₂-b was larger than that of its dppm-capped counterpart, [IrAu₁₂(dppm)₆]³⁺ as evidenced by a blue shift (140 nm) of the photoluminescence (PL) wavelength and DFT calculations. IrAu₁₂-b exhibited PL at 596 nm with a high quantum yield of 87% in deaerated CH₂Cl₂ due to the expanded 1P–1D energy gap and the restricted molecular motions of the bbpe ligands.

Introduction

Atomically precise metal clusters possess size-specific electronic structures characterized by discrete energy levels, just like atoms and molecules. As a result, they exhibit novel physico-chemical properties that differ from their bulk and nanoparticle counterparts and have attracted attention not only for fundamental research but also for various applications.^{1–12} For example, gold clusters with clear energy gaps between the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO) have been demonstrated

to exhibit attractive photofunctions, including photoluminescence (PL), circularly polarized luminescence (CPL), triplet sensitization, and photocatalysis.^{13–20} The widely reported icosahedral Au₁₃ cluster has been considered a representative superatom.^{21–25} Direct stabilization of the Au₁₃ superatom with phosphines and *N*-heterocyclic carbenes (NHCs), without forming Au(I)-ligand staple motifs, often leads to pronounced PL in the red to near-infrared region.^{21,26–30} The heteroatom doping further perturbs the superatomic orbitals, resulting in the drastic modulation of the HOMO–LUMO energy gaps (HL gaps).^{30–38} The diphosphine-protected Au₁₃ clusters such as [Au₁₃(dppm)₆]¹⁵⁺ (dppm: bis(diphenylphosphino)methane) and [Au₁₃(dppe)₅Cl₂]³⁺ (dppe: 1,2-bis(diphenylphosphino)ethane) serve as a platform for the heteroatom doping.^{33–40} The latter has been further modified by the exchange reaction of the Cl ligands with other halogens, alkynyl and subsequently isocyanide ligands.^{41–43}

The ligand shell is not only involved in controlling the geometry of the superatomic cores, but also affects their electronic structures and photophysical processes.^{44–47} More specifically, the interactions of the ligand with the superatomic core and the adjacent ligands are crucial for controlling the HL gap and the excited state dynamics of the cores. For example, Lu *et al.* reported a ligand-induced contraction of the Au₁₃ core

Fig. 1 The molecular structures of the diphosphine ligands and the corresponding Ir@Au₁₂ clusters for (a) [IrAu₁₂(dppe)₅Cl₂]⁺ (**IrAu₁₂-e-Cl**), (b) [IrAu₁₂(dppm)₆]³⁺ (**IrAu₁₂-m**) and (c) [IrAu₁₂(bbpe)₆]³⁺ (**IrAu₁₂-b**).

leading to an expansion of the HL gap and a significant increase in the PL quantum yield (QY).⁴⁸ The use of *N,N'*-dibenzyl-substituted benzimidazolium NHC ligands rigidifies the Au₁₃ superatom through multiple CH- π and π - π interactions in the ligand layer, also resulting in high PLQYs.^{45,49} In contrast to the recent successful applications of various NHC ligands,^{50–53} less systematic studies have been conducted for the diphosphine molecules as capping ligands for the Au₁₃ superatoms.

Bis[benzo[*b*]phosphindole]ethane (bbpe) is a derivative of dppe in which the two phenyl rings are fused by a chemical bond (Fig. 1).⁴⁵ Since the benzo[*b*]phosphindole (bp) framework of bbpe rigidly links the phenyl rings into a planar structure, the degree of freedom of the aromatic units is significantly restricted. This simple chemical modification suppresses the vibrational and rotational modes that can have a significant impact on the relaxation process of the photoexcited state of the Au₁₃ superatoms. Motivated by our recent development of highly luminescent [IrAu₁₂(dppe)₅Cl₂]⁺ cluster (**IrAu₁₂-e-Cl**),³⁵ in this study, we used bbpe as a ligand to stabilize Ir@Au₁₂ superatoms with the intention of further enhancing their PL property (Fig. 1). The cluster synthesis with bbpe unexpectedly yielded a Cl-free cluster [IrAu₁₂(bbpe)₆]³⁺ (**IrAu₁₂-b**) as the main product. The homoleptic capping of the Ir@Au₁₂ core with six bbpe ligands resulted in an almost perfect icosahedral structure. Due to the expanded HL gap as well as the suppressed non-radiative relaxation pathways of the excited state, **IrAu₁₂-b** exhibited bright PL at 596 nm with PLQY as high as 0.87. The remarkable roles of the bbpe ligands on the PL properties of **IrAu₁₂-b** are discussed by comparing the geometry and optical properties of [IrAu₁₂(dppm)₆]³⁺ (**IrAu₁₂-m**) as a reference (Fig. 1).

Results and discussion

Synthesis and structure analysis

The detailed synthetic procedure of **IrAu₁₂-b** is given in the ESI.† The bbpe ligand and the corresponding gold complex, Au₂(-bbpe)Cl₂, were synthesized according to the literature procedure.⁵⁴ The mixture of Au₂(bbpe)Cl₂ and [Ir(COD)Cl]₂ (COD: 1,5-

cyclooctadiene) was co-reduced in CH₂Cl₂. While a typical reduction condition using NaBH₄ at room temperature did not produce any luminescent species, the milder condition using borane-*tert*-butylamine complex^{26,55,56} at 273 K yielded a luminescent solution. The larger agglomerates in the as-synthesized solution were removed by a reverse-phase column chromatography (Wakosil 100C18, Wako-Fuji Film) using a methanol solution containing 0.1 vol% trifluoroacetic acid (TFA) and 0.1 vol% diethylamine (DEA) as an eluent.⁵⁷ The pretreated sample was then analyzed by HPLC using a C₃₀ reverse-phase column (GL Sciences Inc.) as shown in Fig. S1a.† Five well-separated peaks were observed, and three fractions with retention times of 11, 25, and 29 min (peaks 1, 3, and 4 in Fig. S1a,† respectively) contained luminescent species. Electrospray ionization (ESI) mass spectrometry of the HPLC fractions (Fig. S1b†) showed that the major fraction (peak 1 in Fig. S1a†) contained the target cluster (**IrAu₁₂-b**) and that another minor fraction (peak 4 in Fig. S1†) was contaminated by other species such as [IrAu₁₂(bbpe)₅Cl₂]⁺ (Fig. S2†). The PL maxima for peaks 1, 3, and 4 were 598, 632, and 642 nm, respectively (Fig. S1c†). It should be noted that gold clusters with visible PL could not be obtained without [Ir(COD)Cl]₂ in the synthesis.

Since **IrAu₁₂-b** showed the brightest PL among the species obtained, the main fraction (peak 1) was subjected to isolation by a preparative HPLC cycle, followed by recrystallization after treating the solution with NaPF₆. The geometrical structure of **IrAu₁₂-b** was determined by single crystal X-ray diffraction (SCXRD) analysis (Fig. 2a). The Ir@Au₁₂ superatomic core was protected by six bbpe ligands with a coordination pattern, similar to that of **IrAu₁₂-m**.³⁴ However, the superatomic core of **IrAu₁₂-b** has a higher symmetry than that of **IrAu₁₂-m**. A singlet peak in the ³¹P{¹H} NMR spectrum of **IrAu₁₂-b** indicates that Ir atom is located at the center of the Ir@Au₁₂ core (Fig. S3†).³⁵ The symmetric coordination of bbpe ligands to the Ir@Au₁₂ core of **IrAu₁₂-b** was also suggested by a simple peak pattern in the ¹H NMR spectrum (Fig. S4†). The bond lengths in the Ir@Au₁₂ core were compared between **IrAu₁₂-b** and **IrAu₁₂-m** (Fig. 2b, c and Table 1). Surprisingly, all the Ir–Au distances in **IrAu₁₂-b** are identical (2.7397 ± 0.0003 Å), and the distribution of the Au–Au distances is remarkably narrower than that of **IrAu₁₂-m**. Since the average Ir–Au and Au–Au bond lengths of **IrAu₁₂-b** and **IrAu₁₂-m** are very similar (Table 1), the narrower

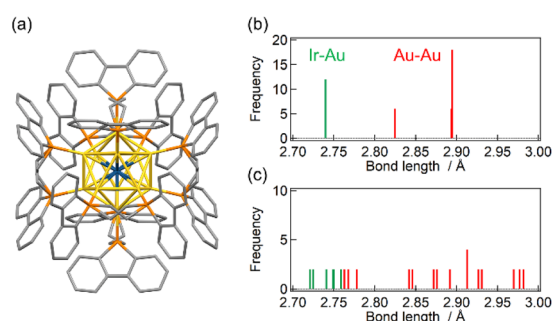

Fig. 2 (a) The structure of IrAu₁₂-b determined by SCXRD. (b and c) Bond length distributions in (b) IrAu₁₂-b and (c) IrAu₁₂-m. Color code: yellow, Au; dark blue, Ir; orange, P; gray, C.

Table 1 Structural Data of IrAu₁₂-b and IrAu₁₂-m Obtained by SCXRD Analysis

	Ir-Au (Å)	Au-Au (Å)	Au-P (Å)	CSM
IrAu₁₂-b	2.740 ± 0.000	2.881 ± 0.028	2.285 ± 0.002	0.014
IrAu₁₂-m (ref. 40)	2.741 ± 0.014	2.883 ± 0.072	2.301 ± 0.013	0.091

bond length distributions for IrAu₁₂-b indicate the formation of a higher symmetric icosahedron of Ir@Au₁₂ by the protection with bbpe. The formation of a nearly ideal icosahedral Ir@Au₁₂ core in IrAu₁₂-b was also confirmed by a much smaller continuous symmetry measure (CSM) value than that of IrAu₁₂-m (Table 1). To the best of our knowledge, the CSM value of 0.014 is comparable to the smallest one (0.013) for the Pd@Au₁₂ core of [PdAu₁₂(dppe)₅(C≡CPh)₂]²⁺ (PdAu₁₂-e-PA)⁴³ among the series of M@Au₁₂ superatoms reported to date (Table S1[†]). Nonetheless, the dopant Pd atom is not situated at the very center of icosahedron in PdAu₁₂-e-PA (Pd-Au: 2.731 ± 0.020 Å).⁴³ The ethylene bridge between the coordinative phosphorous atoms in bbpe may relax the structural strain observed in IrAu₁₂-m where the less flexible methylene bridge imposes constraints incompatible with the surface Au-Au bonds in the Ir@Au₁₂ core. In the case of bbpe, the more rigid bp unit may affect the ethylene bridge conformation, which further influences the distance and orientation of phosphorous atoms on the surface of the Ir@Au₁₂ core. The coordination of six bbpe forms a cuboidal (hexahedral) cage surrounding the icosahedral core (Fig. 2a).

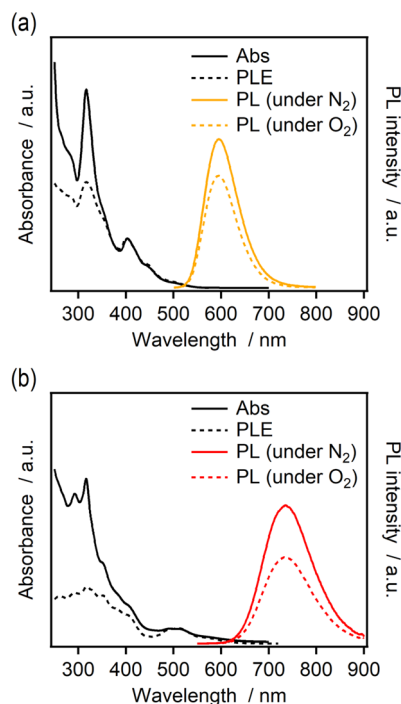

Fig. 3 UV-vis absorption, photoluminescence and excitation spectra of (a) IrAu₁₂-b and (b) IrAu₁₂-m in CH₂Cl₂.

Optical properties

The ligand effect on the electronic structure of the Ir@Au₁₂ core was investigated by UV-vis absorption and luminescence spectroscopy. Fig. 3 shows the absorption, PL, and excitation spectra of IrAu₁₂-b and IrAu₁₂-m in CH₂Cl₂. The absorption onset and PL peak (λ_{max}) of IrAu₁₂-b were blue-shifted by ~100 and ~139 nm, respectively, from those of IrAu₁₂-m.³⁴ These results indicate that the HL gap of IrAu₁₂-b is larger than that of IrAu₁₂-m. The PL was assigned to the excited triplet state-based phosphorescence since the PL intensity decreases in the presence of molecular oxygen. Notably, the slight modification of the ligand structure from dppe to bbpe drastically enhanced the PL efficiency. The PLQY of IrAu₁₂-b was 0.870 in deaerated CH₂Cl₂ determined by the absolute method (JASCO, ILF-135), while that of IrAu₁₂-m was reported to be 0.14.⁴⁰ This PLQY is among the highest reported for the icosahedral M@Au₁₂ clusters.³⁰ The PLQY did not show a clear dependence on the solvent polarity (Table S2 and Fig. S5[†]). The PL lifetime of IrAu₁₂-b in CH₂Cl₂ was determined to be 4.18 μs (Table 2 and Fig. S6[†]), which is slightly longer than that of IrAu₁₂-m (3.6 μs).⁴⁰ The rate constants for the PL (k_r) and the nonradiative process (k_{nr}) of IrAu₁₂-b were calculated to be 2.1×10^5 and 3.1×10^4 s⁻¹, respectively, by assuming that the intersystem crossing (ISC) efficiency is close to unity for a simpler estimation.^{40,58}

The non-radiative relaxation pathway of the excited state of IrAu₁₂-b is significantly suppressed compared to that of IrAu₁₂-m due to the rigid molecular structure of the bbpe ligand. The enlarged PL energy also contributes to the increase in k_r . The highly luminescent property of IrAu₁₂-b was achieved by both (1) accelerating the radiative process and (2) suppressing the non-radiative deactivation process. First, the acceleration of the radiative process is ascribed to the blue shift of the PL maximum, since the phosphorescence rate constant (k_p) is approximately proportional to the square of the radiation energy ($\bar{\nu}_0^2$) according to the relationship of $k_p \approx \bar{\nu}_0^2 f_T$, where f_T is the transition probability from T₁ to S₀. The f_T value depends on the transition probability from S₀ to S₁, the magnitude of spin-orbit coupling constant, and the S₁-T₁ splitting.^{59,60} The absorption probabilities for IrAu₁₂-b and IrAu₁₂-m were comparable, due to the similar absorbance (Fig. S7[†]). The f_T value for IrAu₁₂-b should be increased due to the negligible S₁-T₁ splitting. The more symmetrical Ir@Au₁₂ core of IrAu₁₂-b likely enhances the orthogonality between the 1D to 1P superatomic orbitals, thereby strengthening the spin-orbit coupling.⁶¹ The smaller S₁-T₁ splitting and the strengthened spin-orbit coupling thus contribute to the moderate increase in the k_r value.

Table 2 Photoluminescent properties and kinetic data of the deaerated solutions of IrAu₁₂-b and IrAu₁₂-m in CH₂Cl₂

	λ_{max} (nm)	τ (μs)	PLQY	k_r (s ⁻¹)	k_{nr} (s ⁻¹)
IrAu₁₂-b	596	4.18	0.870	2.1×10^5	3.1×10^4
IrAu₁₂-m (ref. 40)	736	3.6	0.135	3.7×10^4	2.4×10^5

Fig. 4 Configuration of aromatic rings on the surface of (a) $\text{IrAu}_{12}\text{-b}$ and (b) $\text{IrAu}_{12}\text{-m}$.

Second, the k_{nr} value of $\text{IrAu}_{12}\text{-b}$ was drastically reduced, although the spin-orbit coupling also promotes the non-radiative deactivation.⁶⁰ Considering the independence of PLQY on the solvent polarity (Table S1†), the electrostatic interaction between the cationic Ir@Au_{12} core and the counter anion (PF_6^-) has little effect on the PLQY. Therefore, specific interactions between the ligands are expected. Fig. 4 shows the orientation of the aromatic rings in the ligand layers for $\text{IrAu}_{12}\text{-b}$ and $\text{IrAu}_{12}\text{-m}$. The bbpe ligands are oriented so that each end faces the benzene ring of the adjacent one (Fig. 4a). The distances between the hydrogen atoms of a bbpe ligand and an aromatic ring of the adjacent one were estimated to be less than 3.1 Å, which is within the typical distance (2.7–3.2 Å) for the CH- π interaction of the edge-to-face aromatic conformation.⁶² The restricted rotation of phenyl rings fixes the orientation of the bp units, which is advantageous for the bp ring to serve as both a CH donor and π acceptor. As a result, all the bp rings participate in the CH- π interaction network found in the outermost of $\text{IrAu}_{12}\text{-b}$. Three bp units form a triangular CH- π interaction network in a complementary manner, and eight stable triangles are formed at all the corners of the cuboidal cluster. The formation of the CH- π interaction network was also confirmed in the solution state by the ^1H NMR spectral change. Two broad peaks at 6.67 and 7.11 ppm could be assigned to the protons at the 3- and 4-positions of bp-units in $\text{IrAu}_{12}\text{-b}$ (Fig. S4†). Those peaks were shifted upfield by more than 0.8 ppm relative to corresponding protons in the $\text{Au}_2(\text{bbpe})\text{Cl}_2$ precursor due to the ring current effect by the bp unit of the adjacent ligand whereas other two peaks remain unchanged. Thus, the packing of bbpe ligands is solidified, which may also rigidify the central Ir@Au_{12} core, contributing to the suppression of non-radiative pathways and excited state structural relaxations, and the similar geometries of S_1 and T_1 states. On the other hand, such regular network interactions are absent in $\text{IrAu}_{12}\text{-m}$. While both CH- π and π - π interactions between densely packed phenyl groups are occasionally found, the avoidance of steric repulsions between phenyl rings with their rotational freedom seems to be prioritized.

Electrochemistry and electronic structures

The electrochemical measurement was carried out to experimentally determine the energy levels of HOMO and LUMO. Differential pulse voltammetry (DPV) clarified the first

reduction (R1) and oxidation (O1) potentials (vs. Fc/Fc^+ , Fc : ferrocene) for $\text{IrAu}_{12}\text{-b}$ as -1.88 V and 0.76 V, and for $\text{IrAu}_{12}\text{-m}$ as -1.94 V and 0.34 V, respectively (Fig. S8†). Although doping with a low-valent metal atom has been shown to decrease the O1 potential of MAu_{12} clusters,^{35,40} the O1 potential of 0.76 V for $\text{IrAu}_{12}\text{-b}$ is higher than those (0.4 and 0.74 V vs. Fc/Fc^+ , respectively) of undoped $[\text{Au}_{13}(\text{dppm})_6]^{5+}$ and $[\text{Au}_{13}(\text{dppe})_5\text{Cl}_2]^{3+}$.^{35,39} The electrochemical HL gaps (HL_e) for $\text{IrAu}_{12}\text{-b}$ and $\text{IrAu}_{12}\text{-m}$ were estimated to be 2.29 and 2.05 eV, by considering the charging energies (0.35 and 0.24 eV, respectively) estimated from the potential gaps between O1 and O2.⁶³ The HL_e values are consistent with the optical gap (HL_o) as shown in Fig. S8 and S9.† Thus, the large increase in the oxidation potential for $\text{IrAu}_{12}\text{-b}$ results in the larger HL gap (2.29 eV). While the HL_o and PL energies are comparable with those of highly luminescent $\text{IrAu}_{12}\text{-e-Cl}$, the much larger O1 potential makes $\text{IrAu}_{12}\text{-b}$ more tolerant toward the chemical oxidation of the Ir@Au_{12} core.³⁵

The lowest singlet excited state (S_1) of most gold clusters undergoes rapid intersystem crossing to excited triplet states (T_n).⁶¹ The energy differences between the S_1 and T_1 states (ΔE_{ST}) of $\text{IrAu}_{12}\text{-m}$ and $\text{IrAu}_{12}\text{-Cl-e}$ have been reported to be smaller than those of the undoped counterparts, probably because of the small structural difference between the S_1 and T_1 states^{34,35} and the small exchange integral due to the presence of the heteroatom at the center of the superatom.⁶¹ The ΔE_{ST} values estimated by DFT calculations for $\text{IrAu}_{12}\text{-b}$ and $\text{IrAu}_{12}\text{-m}$ were 0.007 and 0.08 eV, respectively (Fig. S10†). The smaller ΔE_{ST} value of $\text{IrAu}_{12}\text{-b}$ should enhance the rate of the intersystem crossing,³⁵ further supporting our assumption of the quantitative ISC efficiency. The calculated T_1 - S_0 gaps of $\text{IrAu}_{12}\text{-b}$ and $\text{IrAu}_{12}\text{-m}$ were 2.11 and 1.54 eV, respectively, which well reproduced the experimental PL energies (2.08 and 1.68 eV, respectively). The large PL blue-shift of $\text{IrAu}_{12}\text{-b}$ is thus considered to originate from the expanded HL gap. The HOMO and LUMO of $\text{IrAu}_{12}\text{-b}$ can be assigned to the superatomic 1P and 1D orbitals, respectively (Fig. 5 and S11†). The electronic structures of the gold clusters have been qualitatively explained by a jellium model in which the energy levels of the superatomic orbitals vary depending on the potential width and depth formed by the metal core.⁶⁴ Fig. S12† shows the DFT-optimized structures and the natural charges of $\text{IrAu}_{12}\text{-b}$ and $\text{IrAu}_{12}\text{-m}$. The optimized structure of $\text{IrAu}_{12}\text{-b}$ is highly symmetric (T -symmetry), while the symmetry of $\text{IrAu}_{12}\text{-m}$ is reduced to S_6 -symmetry by Jahn-Teller distortion. The natural charges for whole Ir@Au_{12} cores of $\text{IrAu}_{12}\text{-b}$ and $\text{IrAu}_{12}\text{-m}$ were estimated to be $+0.53$ and $+0.57$, respectively (Fig. S12†). The similar natural charges between the cores of $\text{IrAu}_{12}\text{-b}$ and $\text{IrAu}_{12}\text{-m}$ suggest the similar depth of the jellium potentials, which, in turn, cannot explain the difference in their HOMO levels.

The 1P and 1D superatomic orbitals of $\text{IrAu}_{12}\text{-b}$ are more degenerated compared to those of $\text{IrAu}_{12}\text{-m}$ (Fig. 5b). This trend can be explained by the higher symmetry of the Ir@Au_{12} core of $\text{IrAu}_{12}\text{-b}$ (CSM = 0.032 for the optimized structure) and the higher symmetry of the phosphine coordination in $\text{IrAu}_{12}\text{-b}$, as described below. Five occupied orbitals below the 1P orbitals have the distinct contribution of the Ir 5d orbitals in a similar

Fig. 5 (a) The positions of Au, Ir, and P atoms in the optimized structures of IrAu₁₂-m (left) and IrAu₁₂-b (right). The top and bottom panels show the view from an edge and a vertex direction of icosahedron, respectively. Color code: yellow, Au; dark blue, Ir; orange, P. (b) Energy levels of the Kohn-Sham orbitals of IrAu₁₂-m and IrAu₁₂-b estimated by DFT calculation.

manner to the electronic structure of IrAu₁₂-Cl-e.³³ Fig. 5a shows the positions of Ir, Au, and P atoms in the DFT-optimized structures of IrAu₁₂-m and IrAu₁₂-b. The superimposed orange dotted lines are the extension of the Ir-Au radial bonds and can be used as a measure to estimate the symmetry of the phosphine ligation. Clearly, the ligation symmetry in IrAu₁₂-b is higher than that in IrAu₁₂-m, since the P atoms of the former are located closer to the guide lines than those of the latter. Indeed, the Au-Au-P angle in IrAu₁₂-b was 104.6°, close to that expected for a perfect *I_h* coordination (120°), while that in IrAu₁₂-m was 94.8° (Fig. 5a). In addition, the CSM value for the P₁₂ cage of IrAu₁₂-b (2.134) was smaller than that of IrAu₁₂-m (5.392), supporting that the phosphine ligands in IrAu₁₂-b coordinate more symmetrically to the Ir@Au₁₂ core. As a result, the ligand field in IrAu₁₂-b is more spherical compared to IrAu₁₂-m, leading to the less energy splitting of the occupied 1P and unoccupied 1D superatomic orbitals (Fig. 5b).^{48,65-67} Although further theoretical and experimental studies are needed to explain the change in the energy levels of the superatomic orbitals, we suggest that the higher *I_h* symmetry of the Ir@Au₁₂ core and the more uniform surface ligation contribute to the larger HL gap for IrAu₁₂-b.

Conclusions

We used bis[benzo[*b*]phosphindole]ethane (bbpe) with a rigid molecular framework to stabilize the Ir@Au₁₂ superatom. The use of bbpe ligands resulted in a hierarchically symmetric cluster: a nearly perfect Ir@Au₁₂ core is capped by eight units of three bbpe ligands, circularly linked by CH- π interactions, arranged at the vertices of a cuboid. We observed interesting PL properties, including a relatively large PL energy (*ca.* 2.1 eV) and large PLQY (0.87), due to the symmetric structure with the rigidified core. These results demonstrate that a slight modification of the ligand structure results in a remarkable improvement of the PL properties of gold superatoms. The [IrAu₁₂(bbpe)₆]³⁺ cluster with high T₁ energy together with the large oxidation potential, *i.e.* deep HOMO level, will find application as a photoredox catalyst.^{35,37}
