Manipulating spin-state conversion to promote asymmetric d–p orbital hybridization for high-efficiency nitrate electroreduction to ammonia

Ke Wang,^{†a} Tong Zhao,^{†a} Hou Wang,^{†a} Shiyu Zhang,^a Rupeng Wang,^a Meng Wang,^a Zixiang He,^a Nan-Qi Ren^a and Shih-Hsin Ho^{*,a}

The electrochemical nitrate reduction reaction (eNO₃[−]RR) presents a sustainable solution for water pollutant management and green ammonia (NH₃) synthesis. However, hindered by the spin-forbidden barrier, the sluggish hydrogenation kinetics of the key intermediate *NO severely limits the production of NH₃. Here, we reported for the first time the realization of a controllable transition of the inner Co spin-state from a low spin to a high spin in CuCo₂O₄ through the Mn doping-driven oxygen vacancy strategy (Mn–CuCo₂O_{4–x}). The elevated Co spin-state enhanced Co 3d (d_{xz}/d_{yz}/d_{z²})*NO 2p asymmetrical orbital hybridization, facilitating *NO intermediate adsorption and the subsequent hydrogenation. Thanks to the Cu–Co synergistic effect enhanced via spin-state modulation, the Mn–CuCo₂O_{4–x}/graphene oxide aerogels (GAs) exhibited an attractive NH₃ yield rate of 2.14 mg h^{−1} cm^{−2} with a dramatic NH₃ faradaic efficiency of 98.37% at an environmentally relevant NO₃[−] level (10 mM NO₃[−]-N), far superior to that of Co₃O₄/GAs, CuCo₂O₄/GAs and as-reported catalysts. Moreover, the strong interfacial interaction between GAs and Mn–CuCo₂O_{4–x} suppresses structural reconstruction of Mn–CuCo₂O_{4–x}, endowing the hybrid with robust stability. Herein, we confirm that spin-state modulation can enhance the Cu–Co synergistic effect and reveal a universal strategy to optimize intermediate adsorption/conversion through the spin-state, opening up a new avenue for deep purification of water pollutants based on spin optimization and providing general principles for the rational design of catalytic materials.

1. Introduction

Increasingly serious problems of nitrogen cycle disruption and environmental contamination pose significant threats to the global ecosystem and public health.^{1–3} Nitrate (NO₃[−]), a predominant contaminant in industrial effluents and agricultural runoff, is identified as a critical contributor to eutrophication, drinking water pollution and ecosystem disruption.^{4,5} Concurrently, ammonia (NH₃) serves as the core raw material for agricultural fertilizers and clean hydrogen energy carriers. The conventional NH₃ production method depends on the energy-consuming Haber–Bosch process, generating a considerable carbon footprint.^{6,7} The electrochemical nitrate reduction reaction (eNO₃[−]RR) can convert NO₃[−] into value-added NH₃ under mild conditions, providing a sustainable solution to the above dual challenges.^{8–10} Despite

its promise, the practical implementation of the eNO₃[−]RR is fundamentally throttled by the kinetically sluggish hydrogenation of a critical intermediate (*NO), where a spin-forbidden barrier imposes severe limitations on reaction rates and faradaic efficiency (FE).

The hydrogenation of *NO constitutes the rate-determining step (RDS) in the eNO₃[−]RR, as its spin-polarized triplet ground state inherently resists forming singlet *HNO intermediates—a classic manifestation of spin selection rules. The Cu–Co bimetallic system in the eNO₃[−]RR partially mitigates this kinetic barrier through functional decoupling, in which the Cu site preferentially adsorbs NO₃[−] and drives the initial deoxygenation reaction and the Co site is responsible for the subsequent *NO hydrogenation conversion.^{11–13} However, current design paradigms predominantly focus on macro/meso-structure engineering (*e.g.*, alloying, defect modulation, and reconstruction).^{14–16} These approaches fail to deeply modulate the essential electronic structure determinants. As a core feature of the d-orbital electron arrangement of transition metals, the spin-state can significantly change the orbital adsorption strength and hybridization mode of metal intermediates, thereby impacting the reaction process.¹⁷ Spinel-type CuCo₂O₄ is an ideal platform for resolving the Co spin-state effect due to its unique structural tunability. Co³⁺ occupies

[†] These authors contributed equally to this work.

the octahedral site in CuCo_2O_4 , and its spin-state is significantly affected by the local coordination environment and lattice stresses.¹⁸ Some studies have shown that by introducing heteroatoms for doping in Co-based materials to induce lattice distortions, the ligand field strength of Co^{3+} can be effectively tuned, consequently enabling controllable switching of the spin-state.^{19–21}

The spin-state of Co sites critically determines the d-orbital energy level configuration, where the HS state exhibits stronger ligand field splitting effects and higher occupancy in the e_g orbitals.^{22,23} This electronic configuration enhances the adsorption and activation of reaction intermediates through optimized orbital interactions, thereby facilitating the RDS in catalytic processes.²⁴ Notably, compelling theoretical and experimental validation for such spin-dependent electronic modulation effects exists in analogous spin-sensitive electrochemical processes, such as the oxygen reduction and evolution reactions, yet this potent strategy remains conspicuously unexplored and underutilized within the eNO_3^-/RR framework.^{25,26} Consequently, it is imperative to elucidate whether HS Co sites can indeed enhance $^*\text{NO}$ adsorption and accelerate its hydrogenation kinetics through changing the orbital hybridization pattern with the $^*\text{NO}$ intermediate and to unravel the interplay between the Co spin-state and the established Cu–Co synergistic effect. These interesting validations will unlock unprecedented activity and selectivity for next generation NO_3^- reduction electrocatalysts.

Here, we utilized CuCo_2O_4 as a model catalytic system and proposed a Mn doping-driven oxygen vacancy strategy to precisely modulate the spin-state of Co. Experimental studies demonstrate that the HS state Co can greatly optimize the adsorption of $^*\text{NO}$ and solve the problem of slow hydrogenation kinetics in the RDS ($^*\text{NO} \rightarrow ^*\text{HNO}$) *via* enhancing the asymmetric hybridization of the Co 3d ($d_{xz}/d_{yz}/d_{z^2}$)– $^*\text{NO}$ 2p orbitals. This spin state-optimized bimetallic synergistic effect endowed Mn– CuCo_2O_4 –x/GAS with excellent catalytic performance (Faradaic Efficiency (FE): 98.37%, yield rate: $2.14 \text{ mg h}^{-1} \text{ cm}^{-2}$ at -0.6 V vs. RHE , and $10 \text{ mM NO}_3^-/\text{N}$), exceeding that of $\text{Co}_3\text{O}_4/\text{GAS}$, $\text{CuCo}_2\text{O}_4/\text{GAS}$ and as-reported catalysts. This work provides a theoretical paradigm for extending the spin-engineering strategy to bimetallic synergistic catalytic systems, while also inaugurating a new dimension of electronic structure modulation for designing efficient NO_3^- conversion catalysts.

2. Experimental section

2.1 Chemicals

All chemical reagents are depicted in Text S1.

2.2 Catalyst preparation

2.2.1 Preparation of GASs. Graphene aerogels (GASs) were synthesized by a hydrothermal combined calcination method. A standard synthesis protocol involved homogenizing 60 mg carboxymethyl cellulose (CMC) with 30 mL graphene oxide (GO) (2 mg mL^{-1}) under ultrasonic processing for 60 min. This precursor solution underwent hydrothermal treatment at 180°C

for 12 h. The synthesized hydrogels were purified using deionized water, freeze-dried, and then thermally treated at 900°C for 2 h under N_2 flow to generate GASs. Finally, the GASs were functionalized with 0.2 mL aminopropyltriethoxysilane (APTES) to impart a positive surface charge.

2.2.2 Preparation of Mn– CuCo_2O_4 –x yolk-shell spheres. A blend of $\text{Cu}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$ (0.1 mmol), $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ (0.2 mmol), a certain amount of $\text{Mn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$, and 8 mL glycerol was introduced into 40 mL isopropanol and stirred to obtain homogeneous solution. This solution was moved into a 100 mL solvothermal reaction vessel lined with Teflon and maintained at a temperature of 180°C over 6 h. The resulting precursor from the solvothermal reaction was subjected to a dual centrifugal rinse using deionized water and ethanol before undergoing a 12 h drying phase at 80°C . The Mn– CuCo_2O_4 –x yolk-shell spheres were then generated by placing the dried precursor in a tube furnace set at 400°C and sustained for 1 h under O_2 conditions. Co_3O_4 and CuCo_2O_4 were prepared similarly to Mn– CuCo_2O_4 –x except that the corresponding metal salts were not added.

2.2.3 Preparation of Mn– CuCo_2O_4 –x/GASs. The Mn– CuCo_2O_4 –x/GAS composite was self-assembled from GASs and CuCo_2O_4 . More specifically, an initial step involves dispersing 0.1 g Mn– CuCo_2O_4 –x yolk-shell spheres in an isopropanol solution loaded with poly(sodium 4-styrenesulfonate) (PSS) (concentration: 0.2 mL PSS and 20 mL isopropanol), yielding PSS-treated Mn– CuCo_2O_4 –x yolk-shell spheres. These spheres were subsequently cleaned twice by centrifugation using alcohol and deionized water. The cleaned product was then dispersed in deionized water and gently added to a GA suspension (60 mL , 0.5 mg mL^{-1}) and stirred for 180 min to achieve a dispersion of Mn– CuCo_2O_4 –x/GAS composite material. The Mn– CuCo_2O_4 –x/GAS composite material was isolated *via* vacuum filtration and sequentially purified with ethanol-aqueous solution under ambient conditions. $\text{Co}_3\text{O}_4/\text{GAS}$ and $\text{CuCo}_2\text{O}_4/\text{GAS}$ were prepared by the same procedure as that of Mn– CuCo_2O_4 –x/GASs.

2.2.4 The preparation of the working electrode. 10 mg of the catalysts were re-dispersed into $470 \mu\text{L}$ of ethanol and $470 \mu\text{L}$ of deionized water, followed by adding $60 \mu\text{L}$ of Nafion solution to make a homogeneous solution. Subsequently, it was ultrasonicated for about 1 h to enable the good dispersion of catalyst inks. Afterwards, $100 \mu\text{L}$ of catalyst inks were dropped onto the carbon paper with an area of 1 cm^2 ($1 \text{ cm} \times 1 \text{ cm}$).

2.3 Characterization

More details on the characterization methods are provided in the SI (Text S2).

2.4 Electrochemical measurements

Electrochemical tests were performed using a three-electrode system connected to a CHI 760E electrochemical workstation in a typical H-cell. The H-cell was separated using a Nafion 117 membrane (Dupont) that was pretreated following reported procedures. The catalysts were used as the working electrode, while an Ag/AgCl electrode and platinum mesh were used as the

reference and counter electrodes, respectively. The electrolytes were Ar-saturated 0.1 M Na₂SO₄ containing 10 mM NO₃⁻-N. All potentials were calibrated to the reversible hydrogen electrode (RHE) scale using the Nernst equation ($E_{\text{RHE}} = E_{\text{Ag/AgCl}} + 0.197 \text{ V} + 0.059 \text{ V} \times \text{pH}$). The current density was normalized to the geometric electrode area ($\sim 1 \text{ cm}^2$). The linear sweep voltammetry (LSV) test was carried out in a three-electrode system at scanning rates of 10 mV s^{-1} . Electrochemical impedance spectroscopy (EIS) measurements were conducted in a frequency range from 10^5 to 0.01 Hz with 5 mV amplitude. Cyclic voltammetry (CV) curves were obtained in the non-faradaic region with different scan rates ($20, 40, 60, 80,$ and 100 mV s^{-1}).

2.5 Analytical methods

Detailed information of nitrogen species concentration determination and the calculation of the eNO₃⁻RR parameters are provided in Text S3 and S4, respectively. Detailed steps of *in situ* Fourier transform infrared spectroscopy (FT-IR), online differential electrochemical mass spectrometry (DEMS), and electron spin resonance (ESR) measurements are described in Text S5–S7, respectively. Density functional theory (DFT) calculations are presented in Text S8.

3. Results and discussion

3.1 Catalyst characterization

The preparation process of the Mn–CuCo₂O_{4–x}/GAs composite framework is shown in Fig. 1a. First, Mn–CuCo₂O_{4–x} yolk-shell nanospheres were prepared *via* solvothermal combined high-

temperature calcination. Subsequently, Mn–CuCo₂O_{4–x}/GAs was synthesized *via* a charge neutralization process. A thorough examination of the microstructure of Mn–CuCo₂O_{4–x} was conducted using scanning electron microscopy (SEM) and transmission electron microscopy (TEM). Mn–CuCo₂O_{4–x} possessed a well-defined yolk-shell architecture, as clearly observed in Fig. 1b and c, characterized by an average particle diameter of approximately 400 nm and distinct surface roughness. Selected area electron diffraction (SAED) analysis confirmed the polycrystalline characteristics of Mn–CuCo₂O_{4–x} (Fig. 1d). Elemental mapping *via* energy-dispersive spectroscopy (EDS) confirmed homogeneous spatial distribution of Mn, Cu, Co, and O constituents throughout the yolk-shell spheres (Fig. 1e–i). Inductively coupled plasma mass spectrometry (ICP-MS) quantified Mn content at 9.36 wt\% (Table S1). The combined results from EDS and ICP-MS analysis conclusively verified the successful incorporation of Mn within the composite structure. The Mn–CuCo glycerate precursors underwent structural evolution into yolk-shell architectures *via* the Ostwald maturation mechanism, as also supported *via* comparative TEM analyses of Co₃O₄ and CuCo₂O₄ phases (Fig. S1–S4).²⁷ To impart Mn–CuCo₂O_{4–x} with negative electrical properties, we utilized PSS for its modification *via* electrostatic self-assembly. During the PSS modification process, the sulfonic acid group (SO₃⁻) of PSS was adsorbed on the surface of Mn–CuCo₂O_{4–x} through electrostatic interaction, forming a stable negatively charged layer (Fig. S5).²⁸ Simultaneously, the amino group (–NH₂) of the APTES molecule underwent a protonation reaction with protons in solution to form positively charged ammonium ions (–NH₃⁺), and –NH₃⁺ was stably anchored to the surface of the GAs *via* covalent bonds, thus conferring a positively charged character.²⁹ Then, the oppositely charged Mn–CuCo₂O_{4–x} and GAs were mixed to form the Mn–CuCo₂O_{4–x}/GAs composites *in situ* through a charge neutralization process. As illustrated in Fig. 1j and k, Mn–CuCo₂O_{4–x} was embedded into the 3D porous skeleton of GAs to form a stable Mn–CuCo₂O_{4–x}/GAs composite framework. The introduction of GAs promoted rapid electron transport while effectively maintaining the stability of the structure, as will be detailed in the subsequent stability characterization section. High-resolution TEM (HRTEM) images demonstrated clear lattice streaks and GA layers, and the measured crystal plane spacing of 0.245 nm corresponded to the (311) crystal plane of CuCo₂O₄, confirming that the spinel structural features were maintained after Mn doping (Fig. 1l). TEM images of Co₃O₄/GAs and CuCo₂O₄/GAs composites suggested that Co₃O₄ and CuCo₂O₄ were also tightly coupled to the GA scaffolds, thus confirming the general applicability of the charge neutralization strategy in constructing metal oxide/GAs composites (Fig. S6 and S7).

The successful synthesis of the CuCo₂O₄ spinel-type framework was confirmed by the X-ray diffraction (XRD) analysis showing consistent crystallographic diffraction peaks at (220), (311), (400), (422), (440), and (533) with the standard card (PDF#78-2177) (Fig. 2a).³⁰ After Mn doping, the diffraction peaks all exhibited a systematic shift to the low angle direction, among which the displacement of the (311) crystal plane was the most significant, originating from the lattice expansion

(f) Mn K-edge WT-EXAFS contour plots for $\text{Mn-CuCo}_2\text{O}_{4-x}/\text{GAS}$, Mn foil, MnO, Mn_2O_3 and MnO_2 . (g) Co K-edge XANES spectra of $\text{CuCo}_2\text{O}_4/\text{GAS}$ and $\text{Mn-CuCo}_2\text{O}_{4-x}/\text{GAS}$ and the standard reference materials, and (h) their corresponding FT-EXAFS spectra. (i) EPR images of $\text{CuCo}_2\text{O}_4/\text{GAS}$ and $\text{Mn-CuCo}_2\text{O}_{4-x}/\text{GAS}$; (j) the influence of Ov on the electron occupancy of Co 3d orbitals. (k) Magnetic hysteresis loops of $\text{CuCo}_2\text{O}_4/\text{GAS}$ and $\text{Mn-CuCo}_2\text{O}_{4-x}/\text{GAS}$.

triggered by the difference in ionic radii between Mn and Co. A weakening of the diffraction peak intensity and a slight broadening of the half height width were also observed, suggesting that the doping process may lead to a decrease in crystallinity. The Raman analysis of CuCo_2O_4 exhibited characteristic peaks at about 475, 521, 627, and 684 cm^{-1} attributed to the E_{2g} , F_{2g} , and A_{1g} vibrational modes of the CoO_6 octahedron (Fig. 2b).³¹ Since there is a spectral overlap between the F_{2g} vibrational mode of the CuO_4 tetrahedron (190 cm^{-1}) and the F_{2g} vibrational mode of the tetrahedral CoO_4 tetrahedron (195 cm^{-1}), the characteristic signals of the CuO_4 tetrahedron were not effectively recognized.^{32,33} The Raman peak of A_{1g} in CuCo_2O_4 was shifted toward the low wave number direction, which originated from the lattice substitution effect of the CoO_6 octahedron by the MnO_6 octahedron with a larger radius. The larger ionic radius can induce local lattice distortion, leading to an increase in metal–oxygen bond length and structural stress, which is consistent with the theoretical model of cation substitution-induced bond length rearrangement.³⁴ Meanwhile, the characteristic vibrational modes of the D and G bands of the graphitic carbon layer of GASs were detected in Raman spectra, confirming the effective coupling of CuCo_2O_4 to GASs.

The chemical valence and coordination environments of the elements were characterized using X-ray photoelectron spectroscopy (XPS) analysis. The XPS full spectra revealed characteristic peaks associated with $\text{Mn-CuCo}_2\text{O}_{4-x}$ and GASs, indicating the successful construction of CuCo_2O_4 and GAS composites (Fig. S8). The high-resolution XPS spectra of the Cu 2p orbital presented characteristic double peaks at 933.9 eV ($2p_{3/2}$) and 954.0 eV ($2p_{1/2}$), confirming that the Cu element exists in the +2-valence state in CuCo_2O_4 and $\text{Mn-CuCo}_2\text{O}_{4-x}$ (Fig. S9).³² Remarkably, the doping of Mn did not change the chemical state of Cu since the binding energy positions and ratios of the two orbitals were not changed. The high-resolution XPS spectra of the Mn 2p orbital were divided into Mn $2p_{3/2}$ and Mn $2p_{1/2}$, and the predominant oxidation state of Mn in the samples was Mn^{4+} (Fig. 2c).³⁵ The Co 2p orbital of CuCo_2O_4 exhibited double state features at 779.7/781.5 eV ($2p_{3/2}$) and 796.6/794.7 eV ($2p_{1/2}$), confirming that Co^{2+} and Co^{3+} coexist in the material, and Co^{3+} occupies the main component (Fig. S10).^{32,36} Notably, the decrease in the $\text{Co}^{3+}/\text{Co}^{2+}$ ratio in $\text{Mn-CuCo}_2\text{O}_{4-x}$ confirmed the preferential occupation of CoO_6 octahedral sites by Mn^{4+} . The O 1s orbitals presented peaks at 529.6, 531.1, and 532.6 eV, corresponding to metal–oxygen (M–O), Ov, and H_2O , respectively, and the Ov concentration of $\text{Mn-CuCo}_2\text{O}_{4-x}$ was higher than that of CuCo_2O_4 (Fig. S11).³⁷ X-ray absorption spectroscopy (XAS) elucidated the electronic state and local coordination of metal elements. Based on the linear combination fitting of the absorption edge positions (Fig. 2d and S12a), the oxidation state of Mn in $\text{Mn-CuCo}_2\text{O}_{4-x}$ was found to be +3.8, which is consistent with the XPS results. Extended X-ray absorption fine structure (EXAFS) analysis of the Mn K-edge (Fig. 2e and S13) revealed no evidence of the Mn–Mn bond, confirming the atomic dispersion of Mn and absence of clusters. The wavelet transform (WT) spectroscopy in R -space (Fig. 2f) of Mn foil, MnO, Mn_2O_3 , MnO_2 , and $\text{Mn-CuCo}_2\text{O}_{4-x}$ demonstrated spectral similarity between $\text{Mn-CuCo}_2\text{O}_{4-x}$ and octahedrally coordinated MnO_2 . These results confirm an octahedral coordination environment for Mn, supporting its primary substitution at octahedral Co sites. The normalized Co K-edge X-ray absorption near-edge structure (XANES) spectra (Fig. 2g and S12b) of CuCo_2O_4 was located between Co_3O_4 and Co_2O_3 , but closer to Co_2O_3 , indicating that Co was predominantly +3 valence in CuCo_2O_4 . In contrast, the Co K-edge XANES spectra of $\text{Mn-CuCo}_2\text{O}_{4-x}$ were shifted towards lower energy, suggesting that the substitution of Co^{3+} by Mn^{4+} leads to an increase in the Co^{2+} ratio. Co K-edge EXAFS analysis (Fig. 2g) revealed a significant reduction in oscillation amplitude for $\text{Mn-CuCo}_2\text{O}_{4-x}$ compared to pristine CuCo_2O_4 , indicative of increased local structural disorder around Co atoms induced by the incorporation of high-valent Mn^{4+} ions. Both the Co K-edge EXAFS spectra of CuCo_2O_4 and $\text{Mn-CuCo}_2\text{O}_{4-x}$ and their corresponding R -space WT spectra (Fig. S14 and S15) show no evidence of Co–Co bonding contributions. Moreover, the EXAFS fitting result (Table S2) of the first-shell peak for CuCo_2O_4 and $\text{Mn-CuCo}_2\text{O}_{4-x}$ revealed that the introduction of Ov reduces the average coordination number of Co.

Prior research has indicated that the addition of metal doping can create lattice distortions and reduce the strength of

the metal–oxygen bond, thereby promoting the creation of oxygen vacancies (Ov).³⁸ Consequently, we analyzed the variations in the Ov concentration in the samples using electron paramagnetic resonance (EPR) tests. Compared with $\text{CuCo}_2\text{O}_4/\text{GAs}$, $\text{Mn-CuCo}_2\text{O}_4\text{-x}/\text{GAs}$ exhibited significantly enhanced signal intensity in EPR spectra, confirming the elevated Ov concentration (Fig. 2i). Since Ov are positively charged defects, they would release free electrons into the surroundings to maintain electrical neutrality. These electrons can be trapped by neighboring Co^{3+} to form transient Co^{2+} , enhancing the spin-state of Co^{3+} . In the pristine CuCo_2O_4 , Co^{3+} is usually in a LS state ($t_{2g}^6 e_g^0$) with a high octahedral coordination field splitting energy, and the electrons preferentially populate the t_{2g} orbitals in the lower energy levels (Fig. 2j). The introduction of Ov induces localized lattice distortion. This structural alteration further modifies the coordination environment of transition metal ions, causing their coordination field splitting energy to fall below the critical threshold. At this point, Co^{3+} transitions from the LS state to the HS state ($t_{2g}^4 e_g^2$), and the number of unpaired electrons increases to four. To validate the proposed introduction of Ov altering the Co^{3+} spin-state, we measured sample magnetism *via* vibrating sample magnetometry. As displayed in Fig. 2k, original CuCo_2O_4 exhibited a weak saturation magnetization intensity whereas the saturation magnetization intensity was significantly increased by the introduction of Ov. This phenomenon indicated that Ov may induce the transition of Co^{3+} from the LS to the HS state through modulation of the localized crystal field and electron occupation, leading to a larger number of spin electrons. In summary, Ov can significantly enhance the number of spin-polarized electrons *via* triggering the HS state transition of Co^{3+} , promoting a more effective “spin promoter” for the orbital interaction between the catalyst and the *NO intermediate.

3.2 Electrocatalytic performance for the NO_3^- RR

The electrocatalytic activities of $\text{Co}_3\text{O}_4/\text{GAs}$, $\text{CuCo}_2\text{O}_4/\text{GAs}$, and $\text{Mn-CuCo}_2\text{O}_4\text{-x}/\text{GAs}$ were assessed in an H-type cell. NO_3^- , NO_2^- , and NH_4^+ concentrations during the eNO_3^- RR were quantified *via* UV-Vis spectrophotometry (Fig. S16–S18). The linear sweep voltammetry (LSV) curves revealed enhanced current densities for $\text{Co}_3\text{O}_4/\text{GAs}$, $\text{CuCo}_2\text{O}_4/\text{GAs}$, and $\text{Mn-CuCo}_2\text{O}_4\text{-x}/\text{GAs}$ versus NO_3^- -free systems, confirming their intrinsic NO_3^- reduction activity (Fig. 3a). Notably, $\text{CuCo}_2\text{O}_4/\text{GAs}$ exhibited higher current density than $\text{Co}_3\text{O}_4/\text{GAs}$, implicating synergistic advantages of Cu–Co bimetallic sites in the eNO_3^- RR. Additionally, $\text{Mn-CuCo}_2\text{O}_4\text{-x}/\text{GAs}$ possessed higher current density and more positive starting reduction potential compared with $\text{CuCo}_2\text{O}_4/\text{GAs}$, suggesting that Mn doping further can enhance the catalytic activity of the eNO_3^- RR. Electrochemical impedance spectrum (EIS)-based analysis of electron transport kinetics showed that $\text{Mn-CuCo}_2\text{O}_4\text{-x}/\text{GAs}$ possessed the smallest capacitive arc radius in the Nyquist plot (Fig. 3b). Moreover, the R_{ct} values showed a dramatic and conclusive trend: $\text{Co}_3\text{O}_4/\text{GAs}$ (66.17 Ω) > $\text{CuCo}_2\text{O}_4/\text{GAs}$ (26.69 Ω) > $\text{Mn-CuCo}_2\text{O}_4\text{-x}/\text{GAs}$ (15.64 Ω), which was in excellent agreement with the observed catalytic activity (Table S3). This

Fig. 3 (a) LSV curves, (b) EIS curves, (c) FE, and (d) $\text{NH}_3\text{-N}$ yield rates of $\text{Co}_3\text{O}_4/\text{GAs}$, $\text{CuCo}_2\text{O}_4/\text{GAs}$, and $\text{Mn-CuCo}_2\text{O}_4\text{-x}/\text{GAs}$. (e) ^1H NMR spectra for $^{14}\text{NO}_3^-$ and $^{15}\text{NO}_3^-$ electrolyte after 1 h of electrolysis. (f) Comparison of eNO_3^- RR performance of $\text{Mn-CuCo}_2\text{O}_4\text{-x}/\text{GAs}$ with that of reported electrocatalysts. (g) *In situ* Raman spectra of $\text{Mn-CuCo}_2\text{O}_4\text{-x}/\text{GAs}$ at different voltages. (h) The cycling stability tests of $\text{Mn-CuCo}_2\text{O}_4\text{-x}/\text{GAs}$.

decrease in R_{ct} unequivocally demonstrated that the charge transfer kinetics for the eNO_3^- RR was significantly enhanced upon introducing Cu, indicating that the bimetallic synergy drastically facilitated the electron transfer process. Most impressively, $\text{Mn-CuCo}_2\text{O}_4\text{-x}/\text{GAs}$ achieved the lowest R_{ct} value, which provided direct electrochemical evidence that the Mn doping and the induced Ov created a more favorable electronic structure, further accelerating the rate-determining electron transfer steps in the eNO_3^- RR. Electrochemical active surface area (ECSA) was quantified by electrochemical double-layer capacitance (C_{dl}) measurements from cyclic voltammetry (CV) in non-faradaic windows (Fig. S19). A higher C_{dl} value was obtained for $\text{Mn-CuCo}_2\text{O}_4\text{-x}/\text{GAs}$ (5.20 mF cm^{-2}) versus $\text{Co}_3\text{O}_4/\text{GAs}$ (1.62 mF cm^{-2}) and $\text{CuCo}_2\text{O}_4/\text{GAs}$ (2.22 mF cm^{-2}), confirming that Cu–Co bimetallic synergism together with Mn doping can increase the active site density, thus enhancing the intrinsic activity of the eNO_3^- RR. Based on the LSV results, -0.4 to -0.8 V vs. RHE was identified as the characteristic potential window. The chronoamperometry quantified the FE and $\text{NH}_3\text{-N}$ yield rates of catalysts (Fig. S20). The trend of volcanic distribution of FE for each catalyst confirmed the existence of a critical starting overpotential for the eNO_3^- RR (Fig. 3c). Excessively negative potentials attenuated FE due to the competing hydrogen evolution reaction (HER). $\text{Mn-CuCo}_2\text{O}_4\text{-x}/\text{GAs}$ exhibited higher FE than both counterparts across tested potentials, achieving a maximum of 98.37% at -0.6 V vs. RHE. $\text{Mn-CuCo}_2\text{O}_4\text{-x}/\text{GAs}$ presented the highest $\text{NH}_3\text{-N}$ yield rate at all potentials; especially at the voltage corresponding to the optimal FE, the $\text{NH}_3\text{-N}$ yield rate was $2.14 \text{ mg h}^{-1} \text{ cm}^{-2}$ (Fig. 3d). Additionally, the selectivity of the catalysts was further evaluated based on the yield rate and FE of the intermediate NO_2^- (Fig. S21). As the applied voltage increased, both the NO_2^- yield rate and corresponding FE of the three catalysts exhibited

a gradual decrease. Among them, Mn-CuCo₂O_{4-x}/GAs maintained the lowest values for both metrics, indicating its greater ability to promote the further conversion of the intermediate NO₂⁻. This highlights the outstanding selectivity of this catalyst in the NO₃⁻ reduction process.

The properties of the nitrogen source in NH₃-N were verified through a blank control. The results revealed almost negligible ammonia production in the blank control, clearly confirming that the nitrogen in the product originated from NO₃⁻ rather than from environmental pollutants (Fig. S22). ¹H-nuclear magnetic resonance (¹H-NMR) was used to monitor the dynamics of the nitrogen conversion pathways. When ¹⁵NO₃⁻ and ¹⁴NO₃⁻ were employed as nitrogen sources, the corresponding ¹⁵NH₄⁺ and ¹⁴NH₄⁺ showed characteristic double-peak and triple-peak splitting patterns, providing direct evidence for the directional conversion of NO₃⁻ to NH₃ (Fig. 3e). Although Mn-CuCo₂O_{4-x}/GAs had excellent catalytic activity, the performance comparison between this material and similar advanced catalysts still needs to be clarified. To this end, we systematically summarized the recent literature for the low-concentration NO₃⁻ system (Fig. 3e and Table S4). Both the FE and NH₃-N yield rate of Mn-CuCo₂O_{4-x}/GAs were significantly better than those of other reported systems, fully demonstrating the leading position of this catalyst in the eNO₃⁻RR. The structural evolution of the Mn-CuCo₂O_{4-x}/GAs electrocatalyst during the eNO₃⁻RR was dynamically tracked using *in situ* Raman spectroscopy. In the absence of GAs, the characteristic Raman peak corresponding to the A_{1g} vibrational mode of Mn-CuCo₂O_{4-x} exhibited a rapid decrease in intensity as the applied potential shifted negatively, indicating insufficient structural stability under operating conditions (Fig. S23). In contrast, after the introduction of GAs, the same characteristic Raman mode remained clearly detectable even at highly negative potentials up to -0.7 V vs. RHE, demonstrating significantly enhanced structural integrity (Fig. 3g). This pronounced contrast underscores the critical role of GAs in stabilizing the active material through strong interfacial interactions, which effectively anchor Mn-CuCo₂O_{4-x}, prevent agglomeration or dissolution, and thus maintain the structural and catalytic durability of the Mn-CuCo₂O_{4-x}/GAs composite throughout the reaction. The FE and NH₃-N yield rate of the system exhibited only minor fluctuations during the continuous electrolysis test for up to 20 h, demonstrating excellent cycling stability (Fig. 3h). The catalysts before and after the reaction were systematically characterized by XRD and TEM, and neither the crystal structure nor the microscopic morphology significantly changed, further verifying the excellent structural stability of Mn-CuCo₂O_{4-x}/GAs at the microscopic level (Fig. S24 and S25).

3.3 Reaction pathways and mechanisms

Time-resolved electrochemical mass spectrometry (DEMS) identified key eNO₃⁻RR intermediates on CuCo₂O₄/GAs and Mn-CuCo₂O_{4-x}/GAs (Fig. 4a, b and S26). *m/z* signals at 15, 16, 17, 30, and 31 revealed *NH, *NH₂, *NO, HNO, and NH₃ intermediate generation. Notably, the characteristic signal peak

(d) EPR spectra of CuCo₂O₄/GAs and Mn-CuCo₂O_{4-x}/GAs in electrolytes without/with NO₃⁻. Gibbs free energy profiles for (e) eNO₃⁻RR and (f) HER on CuCo₂O₄ and Mn-CuCo₂O_{4-x}. (g) DOS of *NO and *HNO species. (h) Differential charge density of critical intermediates adsorbed on CuCo₂O₄ and Mn-CuCo₂O_{4-x} interfaces. (i) PDOS analyses of *NO intermediates adsorbed on CuCo₂O₄ and Mn-CuCo₂O_{4-x}. (j) Schematic illustration of orbital hybridization of Co and *NO in different spin states. (k) Spin charge density of CuCo₂O₄ and Mn-CuCo₂O_{4-x}.

intensity of the relevant intermediates on Mn-CuCo₂O_{4-x}/GAs was significantly higher than that on CuCo₂O₄/GAs, suggesting that the introduction of Ov can significantly enhance the generation capacity of the key intermediates. *Operando* Fourier transform infrared spectroscopy (FT-IR) tracked real-time evolution of surface intermediates during the reaction (Fig. 4c and S27). The vibrational peaks at 1650 cm⁻¹ (δH-O-H) and 3300 cm⁻¹ (νH-O-H) corresponded to interfacial water adsorption and cleavage.^{39,40} The progressive intensification of vibrational signatures at 1460 cm⁻¹ and 3200 cm⁻¹ can be unambiguously assigned to the stretching vibrations of N-H bonds in NH₃ molecules.^{41,42} Based on the key intermediate species and their dynamic evolution patterns monitored online in this study, combined with the mechanistic models reported in the literature, we systematically deduced and constructed the reaction pathway dominated by the stepwise hydrogenation of *NO (Fig. S28). The dynamic evolutionary behavior of active hydrogen species (*H) during the eNO₃⁻RR process was systematically investigated by the *in situ* EPR technique (Fig. 4d). The 5,5-dimethyl-1-pyrroline-N-oxide (DMPO)-*H spin adduct signal intensity for Mn-CuCo₂O_{4-x}/GAs doubled that of CuCo₂O₄/GAs in 0.1 M Na₂SO₄ electrolyte lacking NO₃⁻, confirming that Mn doping effectively promoted hydrolytic dissociation to generate *H. Intriguingly, upon introducing 10 mM NO₃⁻ into the electrolyte, the characteristic signal intensity

corresponding to the *H on Mn-CuCo₂O_{4-x}/GAs exhibited significant attenuation during the electrocatalytic process. This apparent inhibitory effect may stem from the rapid depletion caused by *H and NO₃⁻ reactions. These findings demonstrate that NO₃⁻ reduction on Mn-CuCo₂O_{4-x}/GAs proceeded *via* an *H -mediated indirect pathway and the Ov promoted the hydrogenation process of nitrogen-containing intermediates. To further evaluate the interfacial H₂O dissociation capability of the prepared catalysts, kinetic isotope effect (KIE) tests were conducted by replacing H₂O with D₂O. The KIE value was calculated by comparing the current densities measured in H₂O and D₂O, thereby revealing the dynamic process of *H transfer during H₂O dissociation (Fig. S29). The results indicated that Mn-CuCo₂O_{4-x}/GAs exhibits an average KIE value of 1.24, significantly lower than that of other reference electrocatalysts, demonstrating that the introduction of Ov effectively promotes interfacial H₂O dissociation. Concurrently, it also demonstrated that Ov possesses a significant interface water regulation behavior. Gibbs free energy change (ΔG) plots for CuCo₂O₄ and Mn-CuCo₂O_{4-x} in the eNO₃⁻RR are shown in Fig. 4e. Both CuCo₂O₄ and Mn-CuCo₂O_{4-x} synthesize NH₃ *via* the 8-electron reduction pathway (NO₃⁻ → *NO_3 → *HNO_3 → *NO_2 → *NO → *HNO → *NH → *NH_2 → *NH_3 → NH₃) (Fig. S30 and S31). The ΔG profile identified *NO hydrogenation to *HNO as the rate-determining step (RDS), exhibiting the highest energy barrier. Apparently, Ov lowered the RDS energy barrier from 1.39 eV to 0.41 eV, thereby enhancing eNO₃⁻RR kinetics. Promoting the dissociation of H₂O to produce *H and inhibiting the coupling of *H to produce H₂ are essential to enhance the performance of the eNO₃⁻RR. As illustrated in Fig. 4f, S32 and S33, the H₂O adsorption energy of Mn-CuCo₂O_{4-x} (-0.41 eV) was significantly negatively shifted compared with that of CuCo₂O₄ (-0.19 eV), indicating that its activation of H₂O was largely enhanced. The H₂O dissociation energy barrier was reduced from 0.32 eV to 0.14 eV, effectively promoting the generation of *H active species. Meanwhile, the ΔG of H₂ generation on the surface of Mn-CuCo₂O_{4-x} ($\Delta G = 0.38$ eV) showed a significant positive shift compared with that of CuCo₂O₄ ($\Delta G = 0.07$ eV), suggesting that Ov significantly inhibited the generation of H₂ by the coupling of *H . In conclusion, Ov can lower the hydrogenation barrier of $^*NO \rightarrow ^*HNO$, accelerating the H₂O dissociation and inhibiting the HER side reaction, thereby enhancing selective NO₃⁻-to-NH₃ conversion.

After identifying $^*NO \rightarrow ^*HNO$ as the RDS, density functional theory (DFT) deciphered orbital interaction mechanisms between CuCo₂O₄/Mn-CuCo₂O_{4-x} and reaction intermediates. Density of states analysis of *NO and *HNO intermediates revealed pronounced spin asymmetry in *NO across spin-up/down channels, contrasting with spin symmetry in *HNO (Fig. 4g). This shift in spin configuration revealed a spin rearrangement phenomenon occurring during the reaction, which essentially stems from the pairing process of unpaired electrons. Differential charge density analysis revealed that *NO adsorbed on the surface of Mn-CuCo₂O_{4-x} (0.28|e|) had a higher electron transfer number compared with CuCo₂O₄ (0.16|e|), suggesting that Ov intensified the interfacial electron

transfer process and the bonding tendency to the *NO intermediates was stronger (Fig. 4h).⁴³ Meanwhile, enhanced *NO adsorption was observed on Mn-CuCo₂O_{4-x} (-1.96 eV) relative to CuCo₂O₄ (-1.32 eV). Thus, the spin-state transition promoted *NO adsorption on catalysts, corroborated by projected density of states (PDOS) analysis. Fig. 4i reveals a significant overlap region between the hybridization of the Co-3d orbitals in Mn-CuCo₂O_{4-x} and the N-2p orbitals of *NO and the hybridization energy intervals skewed towards the Fermi energy level, suggesting the existence of a stronger orbital interaction in Mn-CuCo₂O_{4-x} and *NO .⁴³ Furthermore, Mn-CuCo₂O_{4-x} enhanced *NO hydrogenation by stabilizing critical *HNO intermediates, which can be illustrated by the fact that *HNO adsorbed on Mn-CuCo₂O_{4-x} exhibited a larger electron transfer number and a more negative adsorption energy than CuCo₂O_{4-x}.⁴⁴ Based on the previous analysis of the orbital configuration of the Co high spin-state ($t_{2g}^4e_g^2$), its $d_{xz}/d_{yz}/d_{z^2}$ orbitals can form directional hybridization with the σ/π^* antibonding orbitals of *NO , whereas the d_{xy} and $d_{x^2-y^2}$ orbitals are excluded from the effective coupling regime due to symmetry mismatch.^{43,45} In this hybridization, the d_{z^2} orbitals of Co can accept electron occupation from the σ orbitals while the d_{xz}/d_{yz} orbitals feed electrons back to the π^* orbitals. This Co 3d ($d_{xz}/d_{yz}/d_{z^2}$)- *NO 2p asymmetrical orbital hybridization enhanced the adsorption of *NO intermediates and weakened the N-O bond, thereby facilitating *NO hydrogenation to *HNO (Fig. 4j). The unique catalytic properties of CuCo₂O₄ and Mn-CuCo₂O_{4-x} can also be illustrated by the magnetic moment of Co orbitals. The magnetic moment of Co increased from 1.356 μ_B to 1.661 μ_B after the introduction of Ov (Fig. 4k). The elevated magnetic moment is directly associated with the elevated occupancy of the HS state of Co, and the increase in the number of its unpaired electrons facilitates electron exchange between the active site and *NO , accelerating the kinetics of *NO hydrogenation. To summarize, by combining experimental characterization with DFT calculations, we revealed that the elevation of the internal Co spin state in the Cu-Co bimetallic active sites can further enhance the Cu-Co synergistic catalysis through the role of orbital hybridization.

4. Conclusions

In summary, the spin-state of Co³⁺ in spinel CuCo₂O₄ was modulated by an Mn doping-driven Ov strategy, and the controllable transition from the LS state to the HS state was successfully realized, significantly enhancing the Cu-Co bimetallic synergistic catalysis. Experiments and DFT revealed that the HS state Co³⁺ can optimize the adsorption of the key intermediate *NO and hydrogenation step *via* enhancing the asymmetric hybridization of the Co 3d ($d_{xz}/d_{yz}/d_{z^2}$)- *NO 2p orbitals, thus accelerating the eNO₃⁻RR kinetic process. Mn-CuCo₂O_{4-x}/GAs demonstrated superior electrocatalytic performance, achieving an NH₃ yield rate of 2.14 mg h⁻¹ cm⁻² and a faradaic efficiency of 98.37% at -0.6 V vs. RHE, outperforming both Co₃O₄/GAs and CuCo₂O₄/GAs, as well as previously reported catalysts. This work proposes the first theoretical correlation between spin-state modulation and bimetallic synergistic

catalysis, offering a new avenue for the design of high-performance catalytic systems for the deep purification of water pollutants and resource recovery.
