1. This work demonstrates a sustainable electrochemical route for converting nitrate into ammonia using earth-abundant catalysts, enabling pollutant-to-value conversion while avoiding the chemical input and secondary waste associated with conventional biological and physicochemical treatments.
2. The system achieves up to 97% Faradaic efficiency for NH_3 production over a wide nitrate concentration range (10-250 mM) and maintains 86% Faradaic efficiency at environmentally relevant low concentration (1 mM) in neutral conditions, thereby reducing the reliance on strongly alkaline electrolytes and minimizing the need for downstream neutralization.
3. Further work will focus on coupling with renewable electricity and evaluating performance in complex wastewater to further assess practical environmental benefits, and exploring the simultaneous conversion of co-existing pollutants to enhance overall environmental impact.

Abstract: Widespread nitrate contamination in water challenges both aquatic ecosystems and drinking water safety, and the electrocatalytic nitrate reduction to ammonia (eNRA) presents a promising sustainable way to convert pollutants to value-added products. However, most existing eNRA systems operate efficiently only under highly alkaline and concentrated conditions that are incompatible with real wastewater. Here, we report a hollow heterostructured Co₃O₄/CuO catalyst which permits efficient eNRA in neutral aqueous media over a wide range of environmentally relevant nitrate concentrations (1–250 mM). The catalyst achieves NH₃ Faradaic efficiencies above 97% in the 10–250 mM nitrate range and maintains 86% even at 1 mM nitrate. Furthermore, the catalyst showed excellent stability over 100 hours of continuous operation. In situ Fourier transform infrared spectroscopy analysis suggests that the hollow architecture creates a spatially confined microenvironment that accelerates the hydrogenation of NO_x intermediates toward NH₃, and density functional theory calculations indicate the ensemble effect of Co₃O₄ and CuO in reducing the free-energy changes of key nitrate reduction steps. This work highlights a structure engineering strategy in electrocatalysts for efficient nitrate remediation and wastewater treatment.

Introduction

Nitrate accumulation in aquatic environments has become increasingly widespread.^{1–4} In environmental monitoring, nitrate concentrations above 50 mg/L (~0.8 mM) are commonly considered beyond drinking-water standards set by the World Health Organization.⁵ Conventional nitrate remediation strategies, such as biological denitrification and physicochemical separation, mainly focus on nitrate removal through reduction to N₂ or physical separation from water. While effective at controlling nitrate contamination, these approaches involve substantial energy consumption and provide limited capability for resource recovery.^{6–10} For example, biological denitrification generates substantial CO₂ emissions due to the oxidation of organic carbon sources, accompanied by additional N₂O emission and excess sludge production that require secondary treatment.¹¹ In parallel, physicochemical separation methods, such as ion exchange and reverse osmosis, require chemical inputs for resin regeneration or membrane cleaning and generate concentrated brine streams that create additional disposal challenges.^{12–15} In contrast, electrocatalytic nitrate reduction to ammonia (eNRA) has recently emerged as a promising strategy that simultaneously removes nitrate while producing ammonia, which serves as a fundamental chemical

feedstock.^{16–19} When driven by renewable electricity, eNRA provides a sustainable opportunity to couple water purification with green chemical synthesis.^{20–23} Compared with conventional treatment methods, eNRA can potentially reduce the environmental footprint of nitrate remediation. For example, recent studies have demonstrated that electrochemical denitrification systems can reduce CO₂ emissions up to 79.5% compared to biological denitrification, with energy consumption as low as 9.97 kWh kg⁻¹ N under optimized conditions.^{17,24} Moreover, theoretical analyses indicate that the minimum energy requirement for nitrate-to-ammonia conversion is approximately 6.5 kWh kg⁻¹ NH₃, which is lower than that of the Haber-Bosch method (10–13 kWh kg⁻¹) from N₂.^{25,26} suggesting its potential as a low-energy pathway for ammonia production. However, most existing eNRA systems are operated under highly alkaline and concentrated nitrate conditions (e.g., pH ≥ 13, nitrate concentration ≥ 0.1 M) that are very different from those in real wastewater matrices.^{27–31} First, nitrate concentrations can span a wide range and fluctuate over orders of magnitude from agricultural to industrial wastewater, while many catalysts used in eNRA are often optimized for a narrow concentration regime. At low nitrate concentrations, eNRA can lead to accumulation of nitrite intermediates, which lowers ammonia selectivity and introduces additional toxicity concerns.^{32,33} Second, the pH of most municipal wastewater is close to neutral (typically pH 6–8).^{34,35} Maintaining strongly alkaline electrolytes requires the continuous addition of base (e.g., KOH or NaOH). As a result, subsequent pH neutralization prior to discharge or reuse is needed to convert these chemicals into dissolved salts (e.g., K₂SO₄ or NaCl), which increases chemical consumption and generates salt-containing secondary waste streams. To address these challenges, an ideal eNRA catalyst should

satisfy several key requirements: maintaining high selectivity across a wide nitrate concentration range, rapidly consuming reaction intermediates to avoid toxic by-products, and remaining structurally stable during long-term operation under neutral electrolyte conditions.³⁶⁻⁴⁰ However, despite recent progress, achieving all these requirements within a single catalytic system remains difficult.⁴¹⁻⁴³

Hollow Heterostructured Catalysts

Fig. 1 Schematic diagram of hollow heterostructured $\text{Co}_3\text{O}_4/\text{CuO}$ catalysts for eNRA (yellow and blue colours stand for Co_3O_4 and CuO nanosized domains, respectively).

Herein, we report a hollow heterostructured $\text{Co}_3\text{O}_4/\text{CuO}$ catalyst that meets these requirements (Fig. 1). The hollow architecture creates a confined reaction environment for nitrate species within the catalyst interior, which mitigates performance loss under dilute conditions. Meanwhile, atomic ensemble effects at the $\text{Co}_3\text{O}_4/\text{CuO}$ interface facilitate nitrate reduction and subsequent hydrogenation, promoting rapid consumption of reactive nitrogen intermediates. As a result, the catalyst maintains high NH_3 selectivity over a wide nitrate concentration range above commonly accepted pollution thresholds, spanning 1-250 mM in neutral electrolyte, with stable performance over 100 h of continuous operation.

Experimental

Chemicals

All the reagents used were of analytical grade without further purification. Cobalt(II) nitrate hexahydrate ($\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$, 99%), glycerol ($\text{C}_3\text{H}_8\text{O}_3$, 99%), isopropanol ($\text{C}_3\text{H}_8\text{O}$, $\geq 99.5\%$), anhydrous ethanol ($\text{C}_2\text{H}_6\text{O}$), Sulfanilamide ($\text{C}_6\text{H}_8\text{N}_2\text{O}_2\text{S}$, 99%), ethylene glycol ($\text{C}_2\text{H}_6\text{O}_2$, $\geq 99.5\%$) and hydrochloric acid (HCl , AR) were purchased from Macklin. Copper(II) nitrate hemipentahydrate ($\text{Cu}(\text{NO}_3)_2 \cdot 2.5\text{H}_2\text{O}$, 98%) and potassium sulfate (K_2SO_4 , 99%) were obtained from Jiuding Chemical. Copper foam was supplied by Suzhou Keshenghe Metal Materials. Sodium citrate ($\text{C}_6\text{H}_5\text{Na}_3\text{O}_7$, 99%), salicylic acid ($\text{C}_7\text{H}_6\text{O}_3$, 99%), sodium hydroxide (NaOH , 98%), sodium hypochlorite (NaClO , 4%), Naphthyl-diethylenediamine hydrochloride ($\text{C}_{12}\text{H}_{14}\text{N}_2 \cdot 2\text{HCl}$, 99%), Nitric acid (HNO_3 , 65.0-68.0%), sodium nitroferricyanide dihydrate ($\text{Na}_2[\text{Fe}(\text{CN})_5\text{NO}] \cdot 2\text{H}_2\text{O}$, 99%), dimethyl sulfoxide (DMSO, 99%), Phosphoric acid (H_3PO_4 , $\geq 85.0\%$), deuterioxide (D_2O) and potassium nitrate (KNO_3 , 99%) were bought from Aladdin Biochemical Technology. Potassium nitrate- ^{15}N (K^{15}NO_3 , 99 atom% ^{15}N) was purchased from Meryer Biochemical

Technology Co., Ltd. (Shanghai, China). Aqueous solutions were prepared with Millipore water (18.2 $\text{M}\Omega \cdot \text{cm}$).

Material Synthesis

Hollow $\text{Co}_3\text{O}_4/\text{CuO}$ nanoparticles were synthesized by a hydrothermal method followed by annealing. Typically, 0.4 mmol $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ and 0.2 mmol $\text{Cu}(\text{NO}_3)_2 \cdot 2.5\text{H}_2\text{O}$ were dissolved in a mixed solvent of 16 mL $\text{C}_3\text{H}_8\text{O}_3$ and 60 mL $\text{C}_3\text{H}_8\text{O}$ under continuous stirring. The solution was then transferred to a 100 mL Teflon-lined stainless-steel autoclave and heated at 180 °C for 6 h. After cooling to room temperature, the Co/Cu-glycerate was collected by centrifugation, washed thoroughly with anhydrous ethanol, and freeze-dried. Finally, the precursor was annealed in air at 400 °C for 2 h with a ramp rate of 5 °C min^{-1} to obtain the hollow $\text{Co}_3\text{O}_4/\text{CuO}$ nanoparticles. $\text{Co}_3\text{O}_4/\text{CuO}$ nanoparticles with different Co/Cu molar ratios (total metal amount fixed at 0.6 mmol) and single-component CuO were synthesized under the same conditions. For the synthesis of solid $\text{Co}_3\text{O}_4/\text{CuO}$ nanoparticles, 4 mmol $\text{Cu}(\text{NO}_3)_2 \cdot 2.5\text{H}_2\text{O}$ and 4 mmol $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ were co-precipitated in aqueous solution using NaOH . After washed several times until $\text{pH}=7$, the suspension was transferred to a 100 mL PTFE-lined stainless-steel autoclave, where a hydrothermal reaction was performed at 200 °C for 12 h. The resulting precipitate was washed, collected, and annealed in air at 400 °C for 2 h, resulting in the formation of solid CoCu nanoparticles. Cu foam supported $\text{Co}_3\text{O}_4/\text{CuO}$ was synthesized using the same procedure, except a pre-cleaned copper foam was immersed in the precursor solution prior to the reaction.

Characterization and electrochemical measurements

Scanning electron microscopy (SEM) images were acquired using a JSM-7800F microscope. X-ray diffraction (XRD) patterns were collected on a Shimadzu XRD-6000 diffractometer. Transmission electron microscopy (TEM), high-resolution TEM (HRTEM), and energy-dispersive X-ray spectroscopy (EDS) analyses were performed on a JEM-2800 microscope. X-ray photoelectron spectroscopy (XPS) measurements were conducted on a PHI 5000 VersaProbe system. UV-visible absorption spectra were recorded using a Shimadzu UV-3600 spectrophotometer and an Agilent BioTek Synergy H1 microplate reader. Fourier transform infrared (FTIR) spectra were acquired using a Thermo Fisher Nicolet iS50 spectrometer. The elemental compositions of the catalysts were determined by inductively coupled plasma optical emission spectroscopy (ICP-OES, PerkinElmer 8300). Approximately 5 mg of each sample was dissolved in aqua regia in a Teflon-lined vessel and heated at 120 °C for 4 h to ensure complete dissolution. After cooling, the solution was diluted to 50 mL with deionized water. The resulting solution was further diluted by a factor of 20 prior to ICP-OES analysis. All measurements were performed in triplicate, and the average values were used to calculate the weight percentages of Cu and Co. The Brunauer-Emmett-Teller (BET) surface area of the nanoparticles was measured with a ASAP 2460 instrument at 77 K. Prior to measurement, the samples were degassed under vacuum at 150 °C for 12 h. Isotope labelling experiment liquid products were analysed by

^1H nuclear magnetic resonance (NMR) spectroscopy using a Bruker 400 MHz spectrometer.

Electrochemical tests were performed using an Autolab PGSTAT128N potentiostat/galvanostat in a standard three-electrode system. A Ag/AgCl electrode (CHI111, CH Instruments) and a platinum electrode were used as the reference and counter electrodes, respectively. The working electrode was the as-prepared catalyst loaded on copper foam (geometric area: 1 cm^2 , loading: 1.47 mg cm^{-2}). Nitrate reduction experiments were conducted in an H-type cell separated by a Nafion 117 membrane. The electrolyte (0.2 M K_2SO_4 with varying KNO_3 concentrations) was purged with argon for 30 min prior to each experiment. Chronoamperometry measurements were performed at different potentials to quantify the reaction products. All potentials reported vs. Ag/AgCl were converted to the reversible hydrogen electrode (RHE) scale using the formula: E (vs. RHE) = E (vs. Ag/AgCl) + 0.059 \times pH + 0.205 V. For long-term stability tests, electrolysis was conducted at a constant potential for 105 h. For comparison, flow cell tests were conducted using a custom-built flow cell, and the catholyte (50 mM KNO_3 in 0.2 M K_2SO_4) was circulated at 1 mL min^{-1} using a peristaltic pump.

In situ FTIR measurements were performed in a custom thin-layer electrochemical cell using a Thermo Nicolet iS50 spectrometer equipped with a liquid nitrogen-cooled MCT detector. A catalyst-coated glassy carbon disk was used as the working electrode. The electrolyte (0.2 M K_2SO_4 + 50 mM KNO_3) was purged with Ar for 30 min. Spectra were collected at different applied potentials with a resolution of 4 cm^{-1} .

Product analysis

The concentration of produced NH_3 in the catholyte was quantified by the indophenol blue method. Briefly, a diluted sample (2 mL) was mixed with 2.0 mL of an alkaline solution containing 5.0 wt% salicylic acid and 5.0 wt% sodium citrate. Subsequently, 1 mL of 0.05 M NaClO and 0.20 mL of 1.0 wt% sodium nitroprusside solution were added. After incubation in the dark at room temperature for 2 h, the absorbance at 655 nm was measured using a microplate reader. The concentration of NO_2^- was determined by the N-(1-naphthyl)ethylenediamine dihydrochloride colorimetric method, with the absorbance measured at 540 nm using a microplate reader.

The NH_3 yield rate and Faradaic efficiency (FE) were calculated using the following equations:

$$\text{Yield } (\mu\text{g h}^{-1} \text{cm}^{-2}) = (C \times V) / (t \times S)$$

$$\text{FE } (\%) = (n \times F \times C \times V \times 10^{-6}) / (M \times Q) \times 100\%$$

where C is the concentration of total ammonia quantified by the indophenol blue method and expressed as NH_3 equivalent ($\mu\text{g mL}^{-1}$), V is the electrolyte volume (mL), t is the electrolysis time (h), S is the geometric area of the electrode (cm^2), $n = 8$ is the number of electrons transferred for NO_3^- to NH_3 , F is Faraday's constant (96485 C mol^{-1}), $M = 17 \text{ g mol}^{-1}$ is the molar mass of NH_3 , and Q is the total charge passed (C). The factor 10^{-6} converts μg to g for unit consistency.⁴⁴

Energy-related metrics including nitrate conversion, energy efficiency, and specific energy consumption were calculated according to standard electrochemical equations, and the

detailed calculation procedures are provided in the Supporting Information.

DOI: 10.1039/D6GC00484A

Density functional theory (DFT) simulation

The projector augmented wave (PAW) method was employed to accurately describe the many-body interactions between ionic cores and valence electrons. Within the generalized gradient approximation (GGA) framework, the revised Perdew-Burke-Ernzerhof (RPBE) functional was adopted to model the exchange-correlation potential. A plane-wave basis set with a cutoff energy of 520 eV was used. For Brillouin-zone integration, a $3 \times 3 \times 1$ Monkhorst-Pack k-point mesh was applied, and electronic smearing was treated with the first-order Methfessel-Paxton scheme using a width of 0.1 eV. The convergence criteria were set as follows: energy change $\leq 1 \times 10^{-5}$ eV and atomic forces ≤ 0.02 eV/Å. Van der Waals interactions were accounted for using the Grimme-D3 method with zero damping. For model construction, a slab model of the (111) facet was built based on monoclinic CuO , with a 15 Å vacuum layer introduced along the surface normal direction to avoid interactions between periodic slabs; similarly, a (111) facet slab model was constructed using cubic Co_3O_4 , also with a 15 Å vacuum layer introduced on both sides to eliminate interference. Implicit solvation effects were considered in all calculations, and no additional potential ($U = 0$ V) was applied for the computation of the free energy diagram of the eNRA.

Results and Discussion

Hollow $\text{Co}_3\text{O}_4/\text{CuO}$ nanoparticles were synthesized via a template-free hydrothermal method followed by thermal annealing in air at 400 °C. The Co/Cu molar ratios were precisely tuned to 2:1, 1:1, and 1:2 by adjusting the initial precursor concentrations (denoted as H-Co2Cu1, H-Co1Cu1, and H-Co1Cu2, respectively). SEM images reveal that H-Co2Cu1 exhibit a uniform, quasi-spherical morphology with an average diameter of approximately 500 nm (Fig. 2a). TEM further confirms a well-defined hollow structure with a shell thickness of ~ 30 nm (Fig. 2b). While H-Co1Cu1 and H-Co1Cu2 also maintain hollow structures, an increase in Cu content leads to a decreasing in the internal void size and a corresponding increase in shell thickness (Fig. S1). To further evaluate the hollow structure, solid CoCu nanoparticles (denoted as S-CoCu) were synthesized for comparison (Fig. S2). Nitrogen adsorption-desorption measurements reveal a clear hysteresis loop, indicating the presence of mesoporous pores. The BET surface area of H-Co2Cu1 ($30.3 \text{ m}^2 \text{ g}^{-1}$) is higher than that of S-CoCu ($4.5 \text{ m}^2 \text{ g}^{-1}$, Fig. S3), suggesting a more developed porous structure. XRD analysis was used to identify the crystalline phases of the synthesized materials. As shown in Fig. 2c, H-Co2Cu1 exhibits characteristic diffraction peaks can be index to cubic Co_3O_4 (JCPDS No. 78-1969) and monoclinic CuO (JCPDS No. 48-1548). Similarly, all $\text{Co}_3\text{O}_4/\text{CuO}$ composites with different Co/Cu molar ratios exhibit diffraction features corresponding to both oxide phases.⁴⁵ Tuning Co/Cu ratio from 2:1 to 1:2 led to a decreasing of relative intensity of the Co_3O_4 peak at 36.8° , and an increasing

of the CuO peaks at 35.4° and 38.7° (Fig. S4). This compositional trend is further confirmed by ICP-OES results (Table S1).

XPS was conducted to explore the surface chemical states of the Co₃O₄/CuO hollow spheres. The Cu 2p spectrum (Fig. S5a) shows two main peaks at 933.9 and 953.5 eV, corresponding to Cu 2p_{3/2} and Cu 2p_{1/2}, respectively, confirming the presence of Cu²⁺ species in CuO.⁴⁶ The Co 2p spectrum (Fig. S5b) shows two main peaks at 779.7 and 794.6 eV, which can be assigned to Co 2p_{3/2} and Co 2p_{1/2} and indicative of mixed Co²⁺/Co³⁺ oxidation states characteristic of spinel Co₃O₄ structure. HRTEM reveals closely contacted nanosized domains with distinct lattice fringes corresponding to these different phases (Fig. 2d). Lattice spacings of 0.239 nm and 0.253 nm are consistent with the (311) plane of Co₃O₄ and the (002) plane of CuO, respectively. Furthermore, EDS elemental mapping (Fig. 2e) demonstrate the uniform distribution of Cu, Co, and O throughout the entire hollow structure. It should be noted that the uniform elemental distribution reflects the intimate integration of the nanosized grains of CuO and Co₃O₄ within the shell, suggesting the presence of abundant interfaces while maintaining their individual crystalline phases.

Fig. 2 (a) SEM and (b) TEM images of the uniform H-Co2Cu1 nanoparticles with a hollow structure. (c) XRD pattern confirming the coexistence of Co₃O₄ and CuO phases within H-Co2Cu1. (d) HRTEM image of a H-Co2Cu1 nanoparticles. (e) HRTEM image of a single H-Co2Cu1 nanoparticle with corresponding EDS elemental mapping of Cu, Co, and O.

The eNRA performance of the Co₃O₄/CuO catalysts was evaluated in 0.2 M K₂SO₄ electrolyte containing different concentrations of KNO₃ at room temperature.⁴⁷ Linear sweep voltammetry (LSV) was first conducted to assess electrocatalytic behaviour. As shown in Fig. 3a, the onset potential for nitrate reduction is about -0.4 V, and the current density increases monotonically as the potential becomes more negative.

Compared with the electrolyte without nitrate, the presence of NO₃⁻ significantly increases the cathodic current density of H-Co2Cu1, which also confirms its activity towards nitrate reduction. The NH₃ selectivity was then quantified over a wide nitrate concentration window (Fig. 3b-e). The NH₃ FE reaches a maximum at -0.9 V (86-99%) across the tested nitrate concentrations and declines at -1.0 V due to the onset of hydrogen evolution. The hollow Co₃O₄/CuO catalysts exhibit higher NH₃ FEs than S-CoCu across the whole tested nitrate concentration range, with enhancements of approximately 2-3 times. This performance gap highlights the benefit of the hollow architecture for eNRA. Among the hollow series, H-Co2Cu1 exhibits the best overall performance across all concentration regimes compared with H-Co1Cu1 and H-Co1Cu2. Specifically, at a low nitrate concentration of 1 mM KNO₃, the NH₃ FE reaches a maximum of 86.7% at -0.9 V, with a corresponding NH₃ yield rate of 74 μg h⁻¹ cm⁻² (Fig. 3b). At 10 mM KNO₃, the FE peaked at 97.3% at the same potential (Fig. 3c). With increasing nitrate concentration, the performance remained outstanding. At 50 mM and 250 mM KNO₃, the FE achieves remarkable values of 99.8% and 98.7% at -1.0 V, respectively (Fig. 3d and e). To further clarify the trade-off among activity, selectivity, and energy efficiency, additional experiments were carried out over a wider potential range (-0.6 to -1.3 V) using H-Co2Cu1 at a representative nitrate concentration of 50 mM (Fig. S6). As the potential becomes more negative, both the total and NH₃ partial current densities increase continuously, while the NH₃ Faradaic efficiency first increases and then slightly declines at more negative potentials. Meanwhile, the energy efficiency reaches a maximum of 43.99% at -0.8 V and gradually decreases at higher overpotentials, indicating that -0.8 to -1.0 V provides a balanced operating window with high NH₃ partial current density, high FE, and reasonably high energy efficiency, with a minimum energy consumption of 26.95 kWh kg⁻¹ NH₃ (Table S2).^{22, 48-55} In addition, analysis of the liquid products at 50 mM NO₃⁻ shows that the selectivity toward the intermediate NO₂⁻ remains below 2% across the tested potentials (Fig. S7), indicating negligible intermediate accumulation. Meanwhile, H-Co2Cu1 achieves efficient nitrate removal with over 95% NO₃⁻ conversion within 1 h at an initial concentration of 50 mM (Fig. S8). As summarized in Fig. 3f and Table S3, H-Co2Cu1 delivers a superior ammonia formation rate and maintains an FE comparable to or higher than state-of-the-art catalysts across the 1-250 mM concentration window in neutral solution.⁵⁶⁻⁷² These results demonstrate its broad concentration adaptability and practical potential for treating nitrate-contaminated waters with variable compositions.

ARTICLE

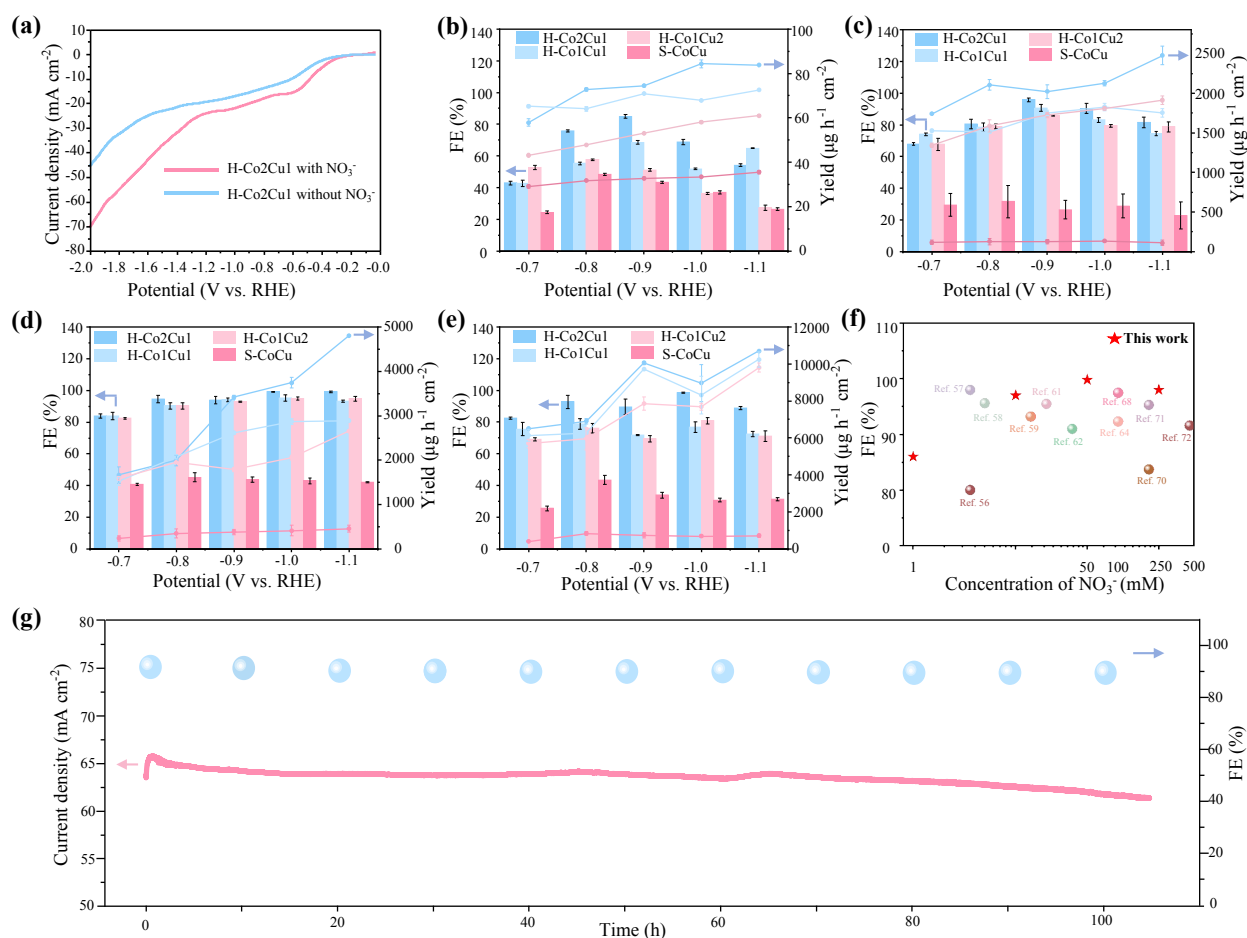

Fig. 3 eNRA performance of the H-Co2Cu1, H-Co1Cu1, H-Co1Cu2 catalysts and S-CoCu nanoparticles measured in an H-type electrolyzer. (a) LSV curves of H-Co2Cu1 in 0.2 M K₂SO₄ electrolyte with and without 10 mM NO₃⁻. (b-e) Faradaic efficiency (FE) for NH₃ and NH₃ yield rate at (b) 1 mM, (c) 10 mM, (d) 50 mM, and (e) 250 mM KNO₃ in 0.2 M K₂SO₄ electrolyte for the four catalysts (Bars denote NH₃ FE, and lines denote NH₃ yield rate). (f) Comparison of the electrocatalytic NRA performance of H-Co2Cu1 with recently reported electrocatalysts. (g) Chronoamperometric response and corresponding NH₃ FE for H-Co2Cu1 recorded at -1.0 V in 0.2 M K₂SO₄ with 50 mM KNO₃ electrolyte during consecutive recycling tests.

Control experiments confirmed that the detected NH₃ originated specifically from nitrate reduction, as negligible ammonia was produced in the absence of NO₃⁻ (Fig. S9). To further verify the nitrogen source of the produced ammonia, isotopic labeling experiments were conducted using K¹⁵NO₃ as the sole nitrate source under the operating conditions of -1.0 V, 50 mM nitrate. The resulting 1H NMR spectra clearly show the characteristic doublet of ¹⁵NH₄⁺, confirming that ammonia is exclusively derived from nitrate reduction (Fig. S10). Moreover, to exclude the contribution from the copper foam support, control experiments were performed using bare copper foam, which exhibited markedly inferior performance (Fig. S11). This result confirms that the outstanding electrochemical activity originates from the hollow heterostructured Co₃O₄/CuO

catalyst rather than the substrate. Importantly, a 105 h durability test of H-Co2Cu1 at -1.0 V (Fig. 3g) shows a stable current density of approximately 65 mA cm⁻² and a consistently high NH₃ FE of about 99%, with no observable morphological changes after long-term operation (Fig. S12). To evaluate the practical applicability, H-Co2Cu1 was tested in a flow cell with identical catalyst loading (1.47 mg cm⁻²) and electrode area (1 cm²). Compared with the H-cell configuration, the total current density increased by 3.4 times, leading to a 3-fold enhancement in the NH₃ yield, while maintaining an NH₃ FE of 79% at -1.0 V (Fig. S13). These results collectively demonstrate the robust long-term operational stability and practical applicability of the hollow heterostructured catalyst for eNRA.

The capability of the hollow $\text{Co}_3\text{O}_4/\text{CuO}$ catalyst to maintain high ammonia selectivity over a broad nitrate concentration range suggests efficient formation and consumption of reaction intermediates under both dilute and concentrated conditions. To gain insight into the underlying mechanisms responsible for this behaviour, we separately examine the roles of the hollow architecture and the ensemble effect of $\text{Co}_3\text{O}_4/\text{CuO}$ interface during eNRA. The effect of the hollow structure on intermediate formation and consumption was investigated using in situ FTIR spectroscopy to directly monitor nitrogen-containing species under reaction conditions. For H-Co2Cu1 (Fig. 4a), no obverse signals related to key reaction intermediates were observed at the open-circuit potential (OCP). Upon applying increasingly cathodic potentials, a negative absorption band at approximately 1331 cm^{-1} emerges, which can be attributed to the asymmetric N-O stretching vibration of adsorbed NO_3^- .⁷³⁻⁷⁵ Meanwhile, a band emerging at approximately 1110 cm^{-1} corresponds to the deoxygenated intermediate $^*\text{NO}$, indicating the onset of nitrate reduction on the catalyst surface.^{73, 76-78} At more negative potentials, additional vibrational features appear in the high-wavenumber region. Bands at $\sim 3730\text{ cm}^{-1}$ and $\sim 3625\text{ cm}^{-1}$ are associated with $-\text{NH}$ -related species, while the band at $\sim 1431\text{ cm}^{-1}$ corresponds to $\text{NH}_3/\text{NH}_4^+$, collectively evidencing the formation of reduced nitrogen products.^{76, 79, 80} Notably, a distinct band at $\sim 1168\text{ cm}^{-1}$ and $\sim 1650\text{ cm}^{-1}$, characteristic of adsorbed $^*\text{NH}_2\text{OH}$, is clearly observed, suggesting the presence of partially hydrogenated nitrogen intermediates during the reaction.^{76, 81} In contrast, S-CoCu exhibit substantially weaker infrared signals for these nitrogen-containing intermediates under identical conditions (Fig. 4b). The suppressed intermediate signatures are consistent with the lower nitrate reduction activity and ammonia selectivity observed, indicating less effective intermediate formation and conversion on the solid catalyst surface.

Fig. 4 Mechanistic investigation of NO_3^- electroreduction. In situ attenuated total reflection Fourier transform infrared (ATR-FTIR) spectra for (a) H-Co2Cu1 and (b) S-CoCu nanoparticles in a solution of 50 mM KNO_3 and 0.2 M K_2SO_4 under different applied potentials.

To explore the role of $\text{Co}_3\text{O}_4/\text{CuO}$ interface, hollow CuO nanoparticles were prepared and evaluated as a reference catalyst (Fig. S14). At both dilute (1 mM) and concentrated (250 mM) nitrate concentrations, the hollow CuO catalyst shows a lower NH_3 FE than the $\text{Co}_3\text{O}_4/\text{CuO}$ catalysts at the optimal potentials (Fig. S15). To gain mechanistic insight into this difference, DFT simulations were performed to explore the free energy profiles of eNRA on $\text{Co}_3\text{O}_4/\text{CuO}$ and CuO.^{80, 82-84} A Co-doped CuO model was constructed to represent the ensemble

effect of CuO domains adjacent to the Co_3O_4 domains in $\text{Co}_3\text{O}_4/\text{CuO}$ catalysts (denoted as Co-CuO), thereby capturing the local electronic perturbation in the interfacial vicinity while avoiding uncertainties associated with explicitly modeling interfaces between crystallographically distinct oxides. Prior studies suggested that the eNRA process is a multistep proton-coupled electron transfer pathway.⁸⁵ Accordingly, we calculated the free energy changes for each elementary step along the reaction sequence: $^*\text{NO}_3 \rightarrow ^*\text{NO}_2 \rightarrow ^*\text{NO} \rightarrow ^*\text{NHO} \rightarrow ^*\text{NH}_2\text{O} \rightarrow ^*\text{NH}_2\text{OH} \rightarrow ^*\text{NH}_2 \rightarrow ^*\text{NH}_3$ (Fig. 5a, Fig. S16 and S17). In the NO_3^- adsorption step, Co incorporation can decrease the adsorption energy of NO_3^- . To quantify this difference, charge density difference analyses were performed for both models (Fig. 5b and c). For Co-CuO, the electron gain of NO_3^- is 0.63 e^- , which is higher than that on the pure CuO (0.59 e^-). This enhanced charge transfer indicating stronger adsorption and facilitating NO_3^- activation.⁸³ In addition, the free energy diagram shows that the rate-determining step (RDS) of the reaction is the hydrogenation of $^*\text{NO}$ to $^*\text{NHO}$. In the presence of Co, the site exhibits a reduced energy uphill for RDS (0.36 eV) compared with pure CuO (0.60 eV). As a further reference, eNRA energetics were evaluated on a Co_3O_4 surface (Fig. S18), where the same RDS is observed but with a significantly higher uphill free-energy change (0.75 eV). Together, these results indicate that the ensemble effect arising from the $\text{Co}_3\text{O}_4/\text{CuO}$ interface more effectively lowers the energetic requirement of the potential-determining step than either single-phase CuO or Co_3O_4 alone.

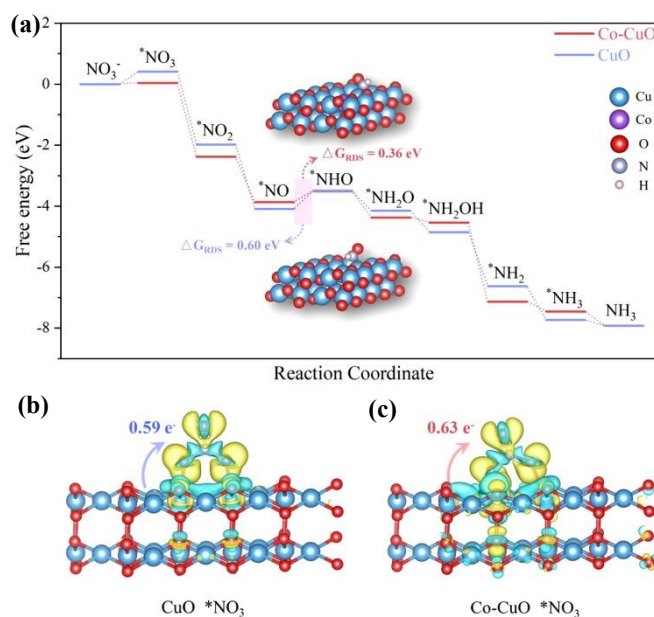

Fig. 5 DFT simulations of eNRA: (a) Calculated free energy diagrams and corresponding structural models for the reaction pathways of CuO and Co-CuO. Differential charge density maps for NO_3^* adsorption on (b) CuO and (c) Co-CuO (yellow and blue regions represent electron accumulation and depletion, respectively).

Conclusion

In summary, we have developed a hollow heterostructured $\text{Co}_3\text{O}_4/\text{CuO}$ catalyst that achieves highly selective and stable eNRA under neutral conditions across a broad nitrate concentration range. The catalyst shows an NH_3 FE exceeding 97% from 10 to 250 mM, and maintains 86% even in highly dilute (1 mM) solutions. The enhanced performance can be attributed to the combined effects of the hollow architecture and the ensemble effect of $\text{Co}_3\text{O}_4/\text{CuO}$ interface. The hollow structure promotes nitrate utilization within the catalyst interior, while the intimate integration of Co_3O_4 and CuO facilitates efficient conversion of nitrate intermediates. This structural engineering strategy of catalysts provides an approach for efficient electrochemical conversion and remediation processes involving dilute feeds, holding particular promise for adaptive wastewater treatment and sustainable nitrogen-recovery technologies.

Author contributions

Li Yao, Shao Ye, and Zhe Li contribute equally to this work. Li Yao performed materials synthesis, characterization and electrocatalytic analysis. Shao Ye performed DFT calculation. Bo Shen supervised the research. All authors participated in discussions and provided suggestions. Bo Shen and Wenlei Zhu contributed to the writing.

Conflicts of interest

The authors declare no conflict of interest.

Data availability

The data supporting the findings of this study are available within the article and its Supplementary Information. Additional data related to the electrochemical measurements and computational models are available from the corresponding author upon reasonable request.
