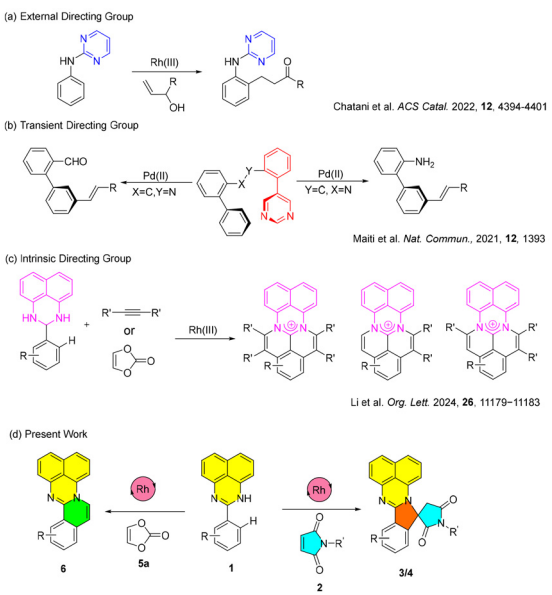
We report a novel Rh(III)-catalyzed perimidine-directed C–H activation strategy for the synthesis of perimidine-fused heterocycles using various types of alkenes. The reaction of 2-aryl perimidines with maleimides in the presence of the $[RhCp^*Cl_2]_2$ catalyst facilitates a cascade [4 + 1] spiro-annulation, affording perimidine-linked isoindoles spiro-fused with succinimides. Conversely, vinylene carbonates provided a fused six-membered ring *via* a [4 + 2] cyclization, yielding perimidine-fused isoquinolines. This methodology is useful for synthesizing a library of polycyclic perimidine-fused heterocycles.

Introduction

In modern organic synthesis, site-selective C–H activation is considered an efficient strategy for the synthesis of complex molecules. Utilizing biologically relevant scaffolds as intrinsic directing groups has gained considerable interest as it circumvents the need for installing and removing external auxiliaries, thereby providing an efficient synthetic route.[1]

Perimidine, a unique fused pyrimidine derivative, holds significant promise across diverse fields including medicine, life sciences, and industrial chemistry.[2] Perimidine derivatives demonstrate a wide spectrum of biological activities, exhibiting antimicrobial,[3] antibacterial,[4] anticancer,[5] antitumor,[6] and anti-inflammatory[7] properties, as well as being useful chemosensors[8] and coloring agents.[9] Perimidine exhibits distinctive electronic features arising from delocalization of the nitrogen lone pair into the naphthalene ring, imparting a unique combination of π-rich and π-deficient character that enhances its reactivity in diverse transformations.[2] This characteristic electronic structure enables perimidine to coordinate with metals by accepting electrons into its low-lying vacant π-orbitals. This coordination also enhances the electropositive character of the metal centre, thereby promoting the coordination of alkenes.[10]

In recent years, pyrimidine has been extensively utilized as a removable auxiliary and transient directing group for directed C–H activation.[10–13] In 2022, Chatani and co-workers reported the activation of the *ortho*-C–H bond of pyrimidine-protected aniline for the oxidative *ortho*-alkylation with secondary allyl alcohols to synthesize β-aryl ketones (eqn (a), Scheme 1).[12] Similarly, in 2021, Maiti and co-workers reported *meta*-olefination of complex biaryls using a palladium catalyst and pyrimidine as a transient directing group *via* reversible imine formation (eqn (b), Scheme 1).[13] Despite the enormous applications in drugs and the synthetic utility of pyrimidines, using it as an intrinsic directing group is still limited. On the other hand, to the best of our knowledge, perimidine-directed C–H activation remains largely unexplored. The only related studies were reported by Li and co-workers, in which 2-aryl-2,3-dihydro-1*H*-perimidines underwent Rh(III)-catalyzed annulation to furnish cationic azaperylene derivatives (eqn (c), Scheme 1).[14]



Scheme 1 Comparison of the present work with some previously reported methods.

Furthermore, intrinsic group directed C–H annulation and spiro-annulation have gathered considerable attention recently.[15–20] Motivated by the directing properties of pyrimidine and the growing interest in intrinsic group-directed annulation and spiro-annulation, and in continuation of our work on C–H functionalization of heterocycles,[21] we turned our attention towards C–H activation using perimidine as an intrinsic directing group (eqn (d), Scheme 1). Herein, we report for the first time an efficient Rh(III)-catalyzed C–H activation strategy utilizing 2-aryl-*1H*-perimidine as an intrinsic directing group for the synthesis of structurally diverse polycyclic spiro-succinimides and isoquinoline-fused perimidines.

Results and discussion

We initiated our study with the reaction between 2-phenyl-1*H*-perimidine (**1a**) and *N*-phenylmaleimide (**2a**) in the presence of $[RhCp^*Cl_2]_2$ (5 mol%), NaOAc (1 equiv.), and AcOH (2 equiv.) in 1 mL of MeOH at 80 °C, which afforded the desired product **3a** in 84% yield (Table 1, entry 1). Notably, alternative C–H activation catalysts such as $[Ru(p\text{-cymene})Cl_2]_2$, $Pd(OAc)_2$, and $[CoCp^*(CO)I_2]$ failed to afford the desired product (Table 1, entries 2–4). Other additives such as AgOAc and $Cu(OAc)_2{\cdot}H_2O$ were ineffective, with no improvement in yield (Table 1, entry 5). Subsequently, various solvents (*e.g.*, 1,2-DCE, ACN, THF, and acetone) were screened to optimize the yield (Table 1, entry 6). These results established MeOH as the most suitable solvent. Substituting AcOH with Na_2CO_3 resulted in a decreased yield of **3a** (52%) (Table 1, entry 7). Similarly, altering the acid source was ineffective, affording a comparable yield (Table 1, entry 8). Conducting the reaction under a N_2 atmosphere resulted in no improvement in yield, with 24% of the starting material remaining, suggesting that air serves as a key oxidant (Table 1, entry 9). No product formation was observed without $[RhCp^*Cl_2]_2$ or NaOAc, while omission of AcOH led to a moderate 47% yield (Table 1, entries 10–12).

With the optimized reaction conditions established, we next explored the substrate scope by varying perimidine derivatives while keeping *N*-phenylmaleimide (**2a**) constant (Scheme 2). Under standard conditions, unsubstituted 2-phenyl-1*H*-perimidine (**1a**) reacted with *N*-phenylmaleimide (**2a**) to afford polycyclic fused succinimide **3a** in 84% yield. We then examined the effect of *para*-substitution on the phenyl ring of perimidine. Electron-donating (**1b**, **1f**) and halogen-substituted (**1c**, **1d**) compounds reacted efficiently with **2a**, affording the corresponding products in yields of 80–88%. In contrast, the fluoro-substituted derivative (**1e**) gave a reduced yield of 62%, while the strongly electron-withdrawing cyano-

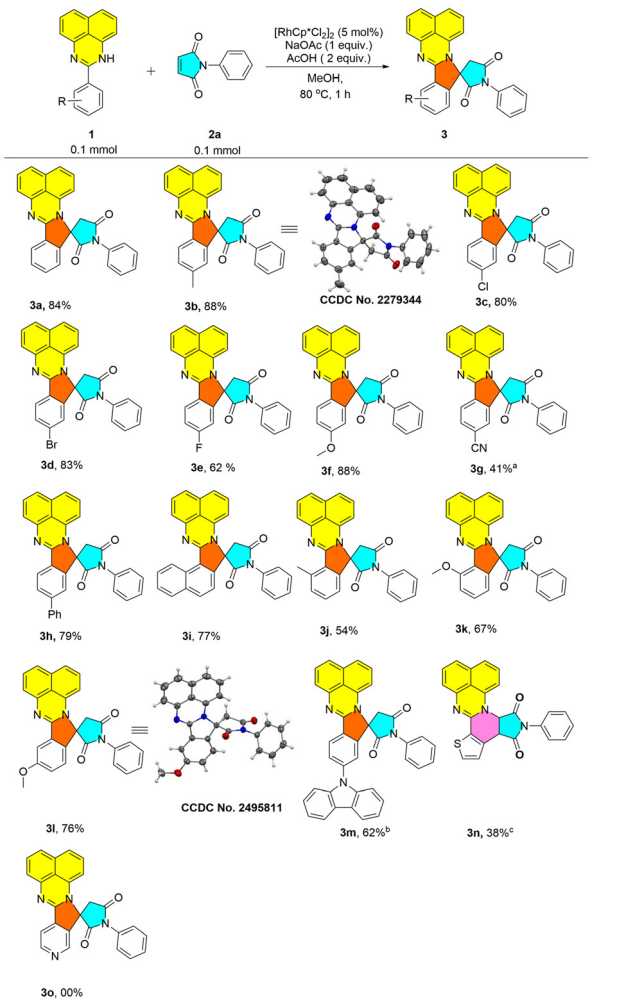
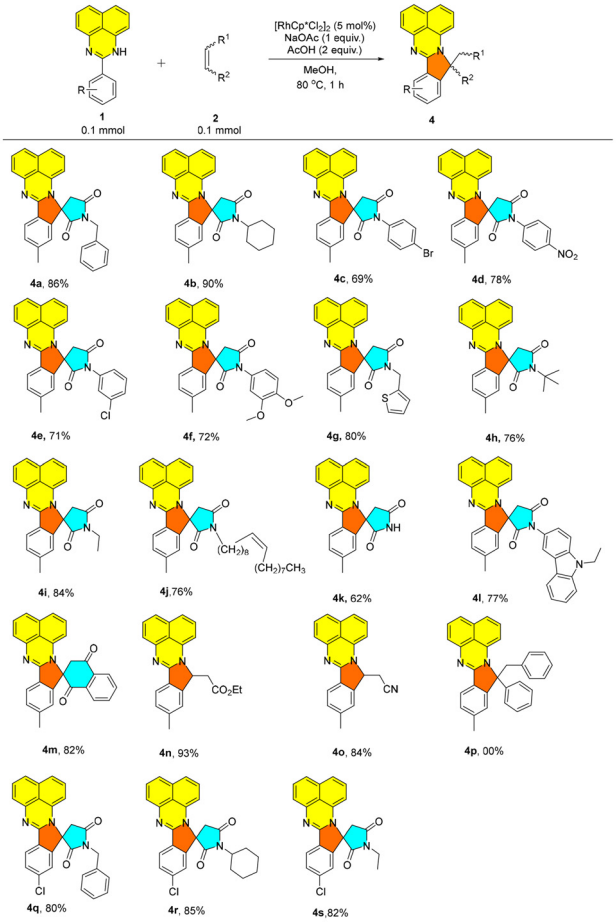
[a] Reaction conditions: **1a** (0.1 mmol), **2a** (0.1 mmol), catalyst (5 mol%), additive 1 (1.0 equiv.), and additive 2 (2.0 equiv.) in solvent (1.0 mL) at 80 °C for 1 h. [b] Isolated yield. [c] Under a N_2 atmosphere; 24% of **1a** was recovered; NR = no reaction.



Scheme 2 Substrate scope for 2-aryl-1*H*-perimidines. Reaction conditions: **1** (0.1 mmol), **2a** (0.1 mmol), 5 mol% (3 mg) $[RhCp^*Cl_2]_2$, 1.0 equiv. (8 mg) NaOAc, and 2.0 equiv. (11 μL) AcOH in 1.0 mL MeOH at 80 °C for 1 h; isolated yield; [a] 20 mol% (3 mg) AgOAc instead of 1 equiv. NaOAc for 24 h; [b] 6 h; [c] 3 h.

substituted perimidine (**1g**), *i.e.*, 4-(2,3-dihydro-1*H*-perimidin-2-yl) benzonitrile, failed to produce the desired product. So, we performed the reaction under the modified conditions using 20 mol% AgOAc instead of NaOAc; the reaction proceeded slowly to provide a low yield of the product **3g** in 24 h. The 4-phenyl-substituted perimidine (**1h**) afforded spirocyclic product **3h** in 79% yield, while naphthyl perimidine (**1i**) delivered **3i** in 77% yield. Notably, *ortho*-substituted derivatives (**1j** and **1k**) were also tolerated, furnishing **3j** and **3k** in moderate yields. All the products were fully characterized by recording ^{1}H, ^{13}C NMR and HRMS spectra. For unambiguous confirmation of the structures, the single crystal X-ray structure of the product **3b** (CCDC no. 2279344) was obtained. The crystal was grown in EtOAc as a solvent by a slow evaporation method. The details of the XRD structure of **3b** are available in the SI. In the case of *meta*-substituted perimidine **1l**, selective activation of the less hindered *ortho* C–H bond afforded product **3l** in 76% yield.[15,17] The structure was further confirmed by performing single crystal-XRD of **3l** (CCDC no. 2495811). The crystal was grown in EtOAc as a solvent by a slow evaporation method (for crystal details, please see the SI). The carbazole-linked perimidine **1m** also underwent smooth transformation with **2a**, delivering **3m** in 62% yield, demonstrating the protocol's compatibility with heterocycle-linked frameworks. Next, we performed the reaction with 2-(thiophen-2-yl)-1*H*-perimidine **1n** with *N*-phenylmaleimide **2a** under the standard reaction conditions. Interestingly, this reaction did not provide the desired spiro-succinimides, instead it provided the [4 + 2] annulated product **3n** in only 38% yield even after a longer reaction time (3 h), and the structure was confirmed by recording ^{1}H, ^{13}C NMR and HRMS spectra. This could be due to the slow reactivity of the 2-(thiophen-2-yl)-1*H*-perimidine **1n** towards the aza-Michael addition step. On the other hand, 2-(pyridin-4-yl)-1*H*-perimidine **1o** was found to be not suitable for this reaction and the corresponding expected product **3o** could not be prepared using this methodology.



Scheme 3 Substrate scope for maleimides/alkenes. Reaction condition: **1** (0.1 mmol), **2** (0.1 mmol), 5 mol% (3 mg) [RhCp*Cl$_2$]$_2$, 1.0 equiv. (8 mg) NaOAc, and 2.0 equiv. (11 μL) AcOH in 1.0 mL MeOH at 80 °C for 1 h; Isolated Yield.

Encouraged by these results, next, we explored the substrate scope with diverse maleimides and alkenes as summarized in Scheme 3. Perimidine **1b** reacted with *N*-benzyl (**2b**) and *N*-cyclohexyl maleimide (**2c**) to afford spirocycles **4a** and **4b** in excellent yields (86% and 90%, respectively). The 4-bromo-substituted maleimide **2d** provided **4c** in 69% yield, while the strongly electron-withdrawing 4-nitro derivative **2e** gave **4d** in a good yield of 78%. The *meta*-substituted maleimide **2f** reacted efficiently with perimidine **1b** to afford spirocycle **4e** in a good yield of 71%. Similarly, 3,4-dimethoxy-substituted maleimide **2g** gave **4f** in 72% yield. Notably, the heteroaryl-linked *N*-methyl thiophene maleimide **2h** also reacted smoothly, furnishing **4g** in 80% yield. The applicability of this methodology was further demonstrated with *N*-alkyl-substituted maleimides **2i** and **2j**, which reacted efficiently with perimidine **1b** to afford **4h** and **4i** in 76% and 84% yields, respectively. Likewise, *N*-oleyl maleimide **2k** reacted with perimidine **1b** to afford the spirocyclized product **4j** in 76% yield. The unsubstituted maleimide **2l** also reacted with **1b**, furnishing **4k** in a moderate yield of 62%. Reaction of **1b** with carbazole-linked maleimide **2m** provided product **4l** in 77% yield. Naphthoquinone **2n**, a cyclic electron-deficient alkene, also afforded the [4 + 1] spirocyclized product **4m** in 82% yield. Acyclic electron-deficient alkenes like ethyl acrylate **2o** and acrylonitrile **2p** reacted with **1b** to provide [4 + 1] annulated perimidines **4n** and **4o** in excellent yields of 93% and 84%, respectively. In contrast, symmetric alkene *trans*-stilbene **2q** remained unreactive under the optimized conditions. Subsequently, 4-chlorophenyl perimidine **1c** was reacted with various maleimides, including *N*-benzyl **2b**, *N*-cyclohexyl **2c**, and *N*-ethyl **2i**. In all instances, the reaction proceeded efficiently, demonstrating the broad scope of this methodology.

After obtaining these encouraging results, we next explored vinylene carbonate as a reaction partner, replacing maleimide. Under the optimized conditions, no reaction occurred. Consequently, we optimized reaction conditions for the reaction of 2-phenyl-1*H*-perimidine **1a** with vinylene carbonate **5a**. After a series of reactions (summarized in Table 2), we found that vinylene carbonates can be reacted with **1a**. Interestingly, the resulting product is a fused six-membered ring formed *via*

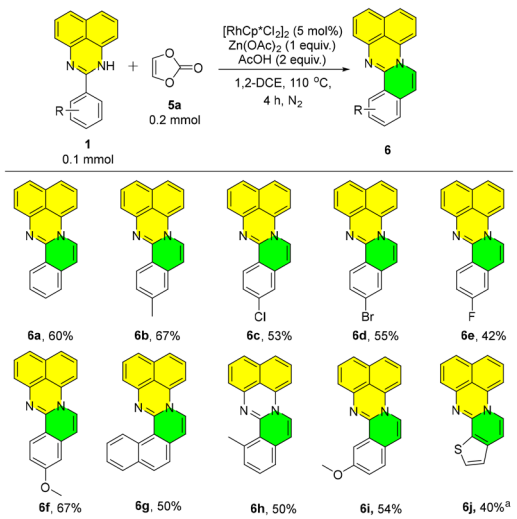
[a] Reaction conditions: **1a** (0.1 mmol), **5a** (0.2 mmol), catalyst (5 mol%), additive 1 (1.0 equiv.), and additive 2 (2.0 equiv.) in solvent (1.0 mL) at 110 °C for 4 h under N_2. [b] Isolated yield. [c] MeOH instead of 1,2-DCE; NR = no reaction.

a [4 + 2] annulation. Among all the screened conditions, entry 1 conditions in Table 2 provided the best result and were therefore considered the optimal reaction conditions.

After establishing the optimal conditions, next we studied the generality of this methodology, and the results are summarized in Scheme 4. We initially reacted 2-phenyl-1*H*-perimidine (**1a**) with vinylene carbonate (**5a**) under the optimal conditions, yielding product **6a** in 60%. Subsequent reactions with *para*-substituted perimidines (**1a–1f**) generally gave good yields, except for the 4-fluoro derivative (**1e**), which produced **6e** in only 42% yield under the standard conditions. We then treated naphthyl-1*H*-perimidine (**1i**) with vinylene carbonate



Scheme 4 Substrate scope of vinylene carbonates. Reaction conditions: **1** (0.1 mmol), **5a** (0.2 mmol), 5 mol% (3 mg) of $[RhCp^*Cl_2]_2$, 1.0 equiv. (18 mg) of $Zn(OAc)_2$, and 2.0 equiv. (11 μL) of AcOH in 1.0 mL of 1,2-DCE at 110 °C for 4 h under N_2; isolated yield; [a] 6 h.

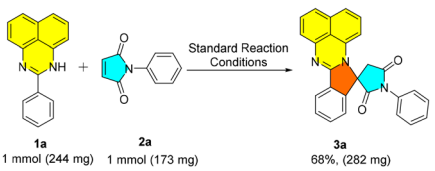
(**5a**), yielding 50% of the [4 + 2] cyclized product **6g**. The substituent at the *ortho* position of 2-phenyl-1*H*-perimidine provided **6h** in a moderate yield of 50%, whereas the *meta* substituted perimidine resulted in the selective activation of the less hindered C–H bond, furnishing a 54% yield of **6i**.[15,17] Next, we treated the heteroaromatic 2-(thiophen-2-yl)-1*H*-perimidine **1n**. The reaction proceeded to furnish the [4 + 2] annulated product **6j** in 6 h.

To demonstrate scalability, the reaction was performed on a 1 mmol scale with perimidine (**1a**) and *N*-phenylmaleimide (**2a**), providing 68% yield of compound **3a** under standard conditions as shown in Scheme 5.

Subsequently, to illustrate late-stage modifications, an additional reaction was carried out using the reported method as shown in Scheme 6.[22] We conducted a ring-opening reaction of spiro-succinimide **3a** with NaOMe, followed by acid work-up yielding product **7** in 85% yield.

To understand the mechanism, we conducted a few control experiments (Scheme 7). Reacting **1e** and **1f** (1 : 1) with *N*-phenyl maleimide **2a** under standard conditions (eqn (a), Scheme 7) yielded **3e** and **3f** in a 1 : 1.3 ratio, suggesting an electrophilic cyclo-rhodation. The deuterium exchange with perimidine **1f** under the optimum reaction conditions for [4 + 1] and [4 + 2] cyclizations resulted in 25% and 78% deuteration, respectively, at both the *ortho* positions, suggesting a reversible C–H activation (eqn (b), Scheme 7).[23,24] The radical trapping experiment with 2 equivalents of BHT under standard reaction conditions proceeded without any significant abatement of yield, *i.e.*, 72% and 48%, respectively, ruling out the probability of any radical being involved in the reaction pathway (eqn (c), Scheme 7). The competitive kinetic isotope effect studies afforded k_H/k_D values of 2.70 and 5.25, respectively, in both cases. This delineates that C–H bond breaking is involved in the rate-determining step (eqn (d) and (e), Scheme 7).

On the basis of our control experiments and previously reported studies[25–32] and the obtained mass spectra, we have proposed a plausible mechanism accounting for the cascade



Scheme 5 1 mmol scale synthesis of **3a**.

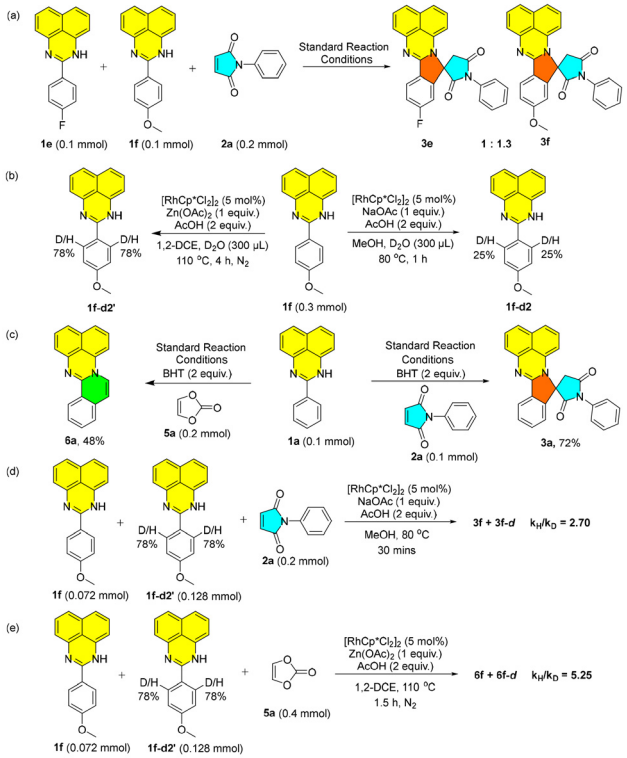
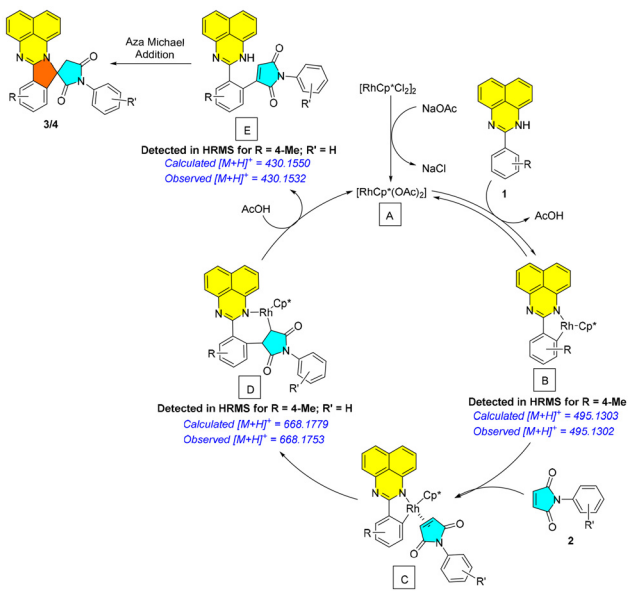
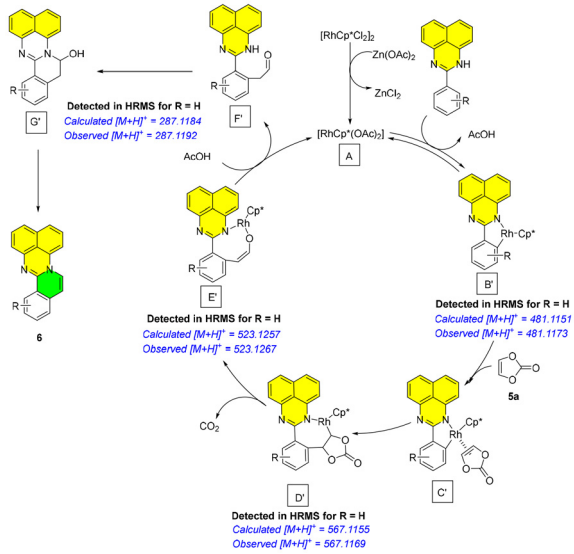


Scheme 7 Control experiments.

annulations (Schemes 8 and 9). Initially, the $[RhCp^*Cl_2]_2$ is activated upon reaction with NaOAc, resulting in the monomeric active catalyst $[RhCp^*(OAc)_2]$ **A**, which undergoes reversible C–H activation with 2-aryl-1*H*-perimidine, leading to the formation of intermediate **B**. The maleimide **2** then coordinates with **B**, yielding complex **C**, which, upon migratory insertion, forms the seven-membered rhodacycle **D**. A β-hydride elimination generates the alkenylated intermediate **E** along with regeneration of the active catalyst **A**. Intermediate **E** then undergoes a rapid aza-Michael addition to form the spiro-annulated product **3**/**4**.



Scheme 8 Plausible reaction mechanism for **3**/**4**.



Scheme 9 Plausible reaction mechanism for **6**.

In the catalytic cycle with vinylene carbonate (Scheme 9), $[RhCp^*Cl_2]_2$ is activated by $Zn(OAc)_2$ to form monomeric Rh(III) complex **A** followed by C–H activation with 2-aryl-1*H*-perimidine to form rhodacycle **B′**. Coordination with vinylene carbonate **5a** forms complex **C′**, which undergoes migratory insertion to yield the seven-membered intermediate **D′**. A β-oxygen elimination and decarboxylation from **D′** generates the eight-membered ring **E′**. The intermediate **E′** undergoes protonation with AcOH, producing intermediate **F′** and regenerates the active catalyst **A**. Intermediate **F′** undergoes intramolecular cyclization and dehydration to afford the [4 + 2] cyclized product **6**.

Conclusions

In conclusion, we have developed an operationally simple and efficient strategy involving cascade C–H activation of 1-aryl-1*H*-perimidines for the synthesis of perimidine-linked spiro-succinimides and isoquinolines. The use of various alkenes, including maleimides, naphthoquinones, ethyl acrylate, and acrylonitrile, predominantly led to the [4 + 1] annulated products *via* selective C–H activation. In contrast, vinylene carbonates exhibited divergent reactivity, furnishing [4 + 2] annulated products. This methodology demonstrates high regioselectivity, broad functional group tolerance, moderate to excellent yields, and scalability, thus offering a valuable approach for the synthesis of structurally diverse heterocycles.
