This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.

ARTICLE

Recent Progress in Iodate Based Nonlinear Optical Crystals

Yu-Wei Kang,^{ab} Chun-Li Hu,^a Cai-Chun Zhang^{ac} and Jiang-Gao Mao^{*ac}Received 00th January 20xx,

Nonlinear optical (NLO) crystals are essential components in modern laser technology. For middle and far-infrared applications, iodates are regarded as highly promising materials due to their intrinsic non-centrosymmetric (NCS) structures, broad optical transparency, pronounced second-order NLO responses, and relatively high laser-induced damage thresholds (LIDTs). However, the tendency of spontaneous crystallization in favor of thermodynamically stable centrosymmetric (CS) phases poses a significant challenge to the rational design of iodates with a macroscopic NCS framework. This review systematically summarizes recent advances over the past decade in the rational designs and controlled syntheses of NCS iodates with significant SHG responses. Emphasis is focused on five key structural-modulation strategies: polymerization of different iodate anions, aliovalent substitution, fluorine substitution, and the synergistic integration of iodate anions with either planar π -conjugated units or tetrahedral building blocks. These approaches collectively enhance local polarization, tune electronic structure, and optimize crystal-growth kinetics, thereby increasing the probability of forming NCS structure and promoting the development of high-performance iodate NLO crystals. Finally, future research directions and emerging trends in this field are outlined to provide a reference for the continued advancement of related research areas.

1. Introduction

Nonlinear optical (NLO) crystals are key materials for laser frequency conversion and spectral expansion, whose performance is crucial for the applicability of laser technology in various fields, including communications, medicine, precision measurement, and frontier scientific research.^{1–7} Currently, commercial NLO crystals, such as KTiOPO_4 (KTP),⁸ KH_2PO_4 (KDP),⁹ and $\beta\text{-BaB}_2\text{O}_4$ ($\beta\text{-BBO}$),¹⁰ mainly operate in the ultraviolet to near-infrared range, but are inadequate for applications in the middle and far-infrared region (2–20 μm). Although commercially infrared NLO crystals (e.g., AgGaS_2 , ZnGeP_2 , AgGaSe_2) partially cover this spectral window, they suffer from inherent performance limitations: narrow bandgaps accompanied by low laser-induced damage thresholds (LIDTs) (AgGaS_2) or inability to achieve phase-matching (AgGaSe_2), or pronounced two-photon absorption near 1 μm (ZnGeP_2).^{11–14}

In response to these limitations, extensive researches have been focused on exploring new infrared (IR) NLO material families. Within chalcogenides, extensive researches have yielded promising candidates that overcome traditional performance limitations. For instance, MgGa_2Se_4 , the first defect-diamond-like (DCL) alkaline-earth metal selenide, exhibits a band gap of 2.96 eV, a high LIDT of $3.0 \times \text{AgGaS}_2$, and a strong second-harmonic-generation (SHG) response of $0.9 \times \text{AgGaS}_2$ with type-I phase-matching (PM).¹⁵ More notably, $\text{Li}_4\text{MgGe}_2\text{S}_7$, the first alkali and alkaline-earth metal diamond-

like (DL) IR NLO material, features a unique honeycomb-like framework that yields an exceptional band gap of 4.12 eV, which is the largest among quaternary metal chalcogenides, leading to a high LIDT of $7 \times \text{AgGaS}_2$, while maintaining a moderate SHG response of $0.7 \times \text{AgGaS}_2$ with type-I PM.¹⁶

Despite these advances, chalcogenides still face inherent challenges. The trade-off between band gap and nonlinearity persists: MgGa_2Se_4 offers stronger SHG intensity but a narrower band gap, while $\text{Li}_4\text{MgGe}_2\text{S}_7$ achieves a wider band gap at the expense of SHG intensity. Additionally, issues such as two-photon absorption and difficulties in crystal growth further limit their practical application, motivating the search for alternative systems with more balanced performance.

Against this backdrop, iodates have emerged as an important class of materials for middle and far IR NLO crystals, owing to their distinct structural features and excellent comprehensive performance. Unlike chalcogenides, which achieve large SHG intensity but have lower LIDT, or halides, which prioritize LIDT at the expense of SHG, iodates achieve a favorable balance across multiple performance metrics. The stereochemically active lone pairs (SCALPs) electrons on the I^{5+} ion induce highly distorted trigonal pyramidal $[\text{IO}_3]^-$ and see-saw shaped $[\text{IO}_4]^{3-}$ units, which generate pronounced local polarization and hyperpolarizability. This characteristic not only favors the formation of non-centrosymmetric (NCS) crystal structures but also imparts large second-order NLO coefficients when these asymmetric units are aligned in their structures and significant birefringence. Furthermore, the low phonon energy of the I–O bonds enables broad optical transmission across key atmospheric windows, particularly in the 3–5 μm and 8–12 μm regions.¹⁷ This combination of strong SHG response and wide

infrared transparency endows iodates as promising candidates for mid-infrared laser technology.

Despite the notable advantages of iodates, their designs and syntheses still encounter two fundamental challenges. First, the SCALPs tend to adopt antiparallel dipole orientations, favoring the formation of thermodynamically more stable CS structures, which makes the directed assembly of NCS phases particularly difficult. Second, even when the NCS structure is successfully realized, it remains essential to simultaneously optimize multiple performance parameters, including the NLO coefficient, band gap, birefringence, and LIDTs, to meet the requirements of practical materials and devices.¹⁸⁻²⁴ Notably, the birefringence (Δn) is highly wavelength-dependent: for visible and near-IR applications, a moderate Δn (≥ 0.03) is sufficient, whereas for UV regions, the increased material dispersion demands a larger birefringence (≥ 0.07) to achieve PM. To address these challenges, researchers have recently developed a variety of effective structural-modulation strategies to systematically increase the probability of NCS crystallization while enhancing overall optical performance.

In fact, research in this field has progressed through a series of pivotal developments. In 2015, our group systematically reviewed the progress in metal iodate NLO crystals, focusing on systems with the NCS structures and notable SHG performance.²⁵ In 2017, Guo et al. noted the potential of iodates for applications spanning the visible to mid-infrared spectrum in their review of middle and far-infrared NLO materials.²⁶ In 2021, our group further summarized novel strategies for high-performance SHG materials, including a few iodates as representative examples to illustrate design approaches such as iodate polymerization and aliovalent substitution.²⁷ In the same year, Wu et al. carried out a systematic theoretical and experimental analysis of structure-property relationships in metal iodates,²⁸ while Guo et al. and Kong et al. reviewed the influence of SCALPs on SHG activity.^{29, 30} Subsequent work has continued to advance the field. In 2023, the OK group demonstrated the application of aliovalent substitution strategies in d^0 -transition-metal/gallium iodates,³¹ and Yu et al. conducted a comprehensive survey of

fluorine-containing iodate NLO crystals.¹⁷ Most recently, in 2025, Wang et al. also discussed the structure-property correlations of iodates in their review of advances in d^0 -transition-metal oxyfluorides.³² In conclusion, these contributions have significantly propelled the rational designs and performance optimizations of metal iodates.

Despite recent progress on exploring specific design strategies for iodate-based NLO materials, a systematic overview that consolidates these advances and elucidates their underlying structure-property relationships is still needed. This review highlights key advances over the past decade, centering on five core strategies: polymerization of $[\text{IO}_3^-]/[\text{IO}_4]^{3-}$ units, aliovalent substitution, fluorine substitution, and combination of different promising units (π -conjugated and tetrahedral) (**Fig. 1**). By systematically reviewing the synthetic strategies and analyzing the structure-property relationships of representative compounds, we elucidate how these approaches help overcome symmetry constraints and balance multiple performance parameters. This work aims to provide a clear theoretical foundation and future directions for the rational design and controlled synthesis of high-performance iodate NLO crystals.

2. Polymerizations of the different iodate anions

I atom exhibits a wide range of oxidation states (e.g., +3 and +5) and diverse coordination geometries. For I^{5+} , with its SCALPs showing pronounced stereochemical activity, triggering a second-order Jahn-Teller (SOJT) distortion that leads to significant polyhedral distortion. Specifically, the SCALPs occupy one side of the I atom, pushing the O atoms to the opposite side and forming highly distorted $[\text{IO}_3]^-$ trigonal pyramids or “see-saw” shaped $[\text{IO}_4]^{3-}$ units. These building blocks can further polymerize via O bridges to form a variety of polyiodate units, such as $[\text{I}_2\text{O}_5]$ dimer,³³⁻³⁵ $[\text{I}_3\text{O}_8]^-$ trimer,³⁶⁻³⁸ pinwheel-shaped $[\text{I}_3\text{O}_{10}]^{5-}$,³⁹ $[\text{I}_4\text{O}_{11}]^{2-}$ tetramer,^{40,41} $[\text{I}_5\text{O}_{14}]^{3-}$ pentamer,^{42,43} and 1D $[\text{I}_7\text{O}_{18}(\text{OH})]^{2-}$ chain.⁴⁴ Polyiodates not only increase the spatial density of functional units but also raise the local concentration of lone-pair electrons within the unit cell, thereby significantly

enhancing the probability of NCS structure formation and favoring materials with strong optical anisotropy. In our previous work, a series of noble-metal iodates with excellent SHG responses was discovered, including α -NaAu(IO₃)₄ (1.17 × KTP at 2.05 μm),⁴⁵ K₂Au(IO₃)₅ (1.0 × KTP at 2.05 μm),⁴⁶ and BaPd(IO₃)₄ (0.4 × KTP at 2.05 μm).⁴⁷ These compounds contain [M(IO₃)₄] (M = Au³⁺, Pd²⁺) units, in which a square-planar [MO₄] group shares O vertices with four [IO₃]⁻ units located on the same side of the plane. The square-planar [MO₄] configuration has been shown to serve as an effective structural direct agent,

promoting the ordered alignment of high-density SCALPs. Inspired by this, the I³⁺ cation possesses two lone pairs.^{48,49} To minimize electron-electron repulsion, its four ligands tend to adopt a coplanar arrangement, forming a square-planar [I^{III}O₄]⁵⁻ unit that exhibits significant optical anisotropy. This section reviews the structural features and optical properties of iodates containing diverse polyanionic units. Representative polyiodates exhibiting notable SHG responses are summarized in **Table 1**.

Table 1. Optical properties of polyiodates.

Powder SHG data (Kurtz–Perry method) provide an initial indicator of NLO potential.⁵² N/A = not available or not reported.

2.1 A₂[I^{III}(VO₃)₄]VO₃ (A = K, NH₄)

These iodate single crystals were synthesized via conventional hydrothermal methods at 160 °C for 3 days. In the preparation of K₂[I^{III}(VO₃)₄]VO₃, SeO₂ is added to act as a mild

reducing agent, converting a portion of I⁵⁺ to I³⁺, thereby enabling the co-incorporation of I in different oxidation states within the same lattice.^{48,49} K₂[I^{III}(VO₃)₄]VO₃, (NH₄)₂[I^{III}(VO₃)₄]VO₃, and K_{1.03}(NH₄)_{0.97}(I₅O₁₂)(IO₃) all crystallize

Fig. 2 (a) $[I^{III}O_4]^{5-}$, $[I^VO_3]^-$ and $[I^{III}(I^VO_3)_4]^-$ unit. (b) View of the structure of $A_2[I^{III}(I^VO_3)_4]I^VO_3$ ($A = K^+ / NH_4^+$) down the a -axis. Copyright 2025 and 2023 Wiley-VCH.

in the NCS polar space group $Cmc2_1$. In these structures, the I^{3+} ion is coordinated by four O atoms from distinct $[I^VO_3]^-$ groups, forming a square-planar $[I^{III}O_4]^{5-}$ unit. All four $[I^VO_3]^-$ groups are situated on the same side of this square plane, collectively assembling into a novel bowl-shaped polymeric unit $[I^{III}(I^VO_3)_4]^-$ (**Fig. 2a**). Owing to the structural directing influence of the $[I^{III}O_4]^{5-}$ unit, the lone pairs of electrons in each $[I^VO_3]^-$ group adopt a highly consistent *cis*-orientation. This alignment imparts significant macroscopic polarity and remarkable optical anisotropy to the polymeric anion. To achieve charge balance, cations (K^+ , NH_4^+) along with isolated $[I^VO_3]^-$ units occupy the interstitial spaces between these bowl-shaped assemblies (**Fig. 2b**). This ordered and highly polarized structural arrangement results in SHG responses, with measured intensity approximately 21.6, 16, and 19.6 times that of KDP, respectively. The planar square $[I^{III}O_4]^{5-}$ group can be effectively replaced by its structural analogs, $[PdO_4]^{6-}$ and $[AuO_4]^{5-}$, to produce compounds with equally large SHG responses. The substitution requires aligning all $[IO_3]^-$ units on the same side of

the plane. This unilateral orientation serves as a necessary structural unit for generating the significantly giant SHG response.

2.2 $K_2Zn(IO_3)_3(I_2O_5(OH))(IO_2(OH))(H_2O)$

$K_2Zn(IO_3)_3(I_2O_5(OH))(IO_2(OH))(H_2O)$ was synthesized via mild hydrothermal conditions at 180 °C (3 days). The $[ZnO_6]^{10-}$ octahedron acts as a central connector, being coordinated by one $[IO_3]^-$ and one $[I_2O_5(OH)]^-$ unit to form a polar, “tumbler-like” $[Zn(IO_3)(I_2O_5(OH))]$ polyanion (**Fig. 3a**).³⁵ Four additional $[IO_3]^-$ groups attach through the four equatorial O atoms of the same octahedron, causing significant distortion and creating a top-heavy structure as the fundamental building block $[Zn(IO_3)_5(I_2O_5(OH))]^{4-}$ (**Fig. 3b**). Steric hindrance from $[I_2O_5(OH)]^-$ and hydrogen-bonding interactions ensure that the four equatorial $[IO_3]^-$ groups are nearly identical in orientation and alignment. These units form a two-dimensional (2D) $^2_\infty [Zn(IO_3)_3(I_2O_5(OH))]^{2-}$ layer in the ab plane (**Fig. 3c**), with K^+ ions, neutral $[IO_2(OH)]$ anions, and water molecules located at interlayer space (**Fig. 3d**). This hierarchical structure reveals

Fig. 3 (a) The “tumbler-like” $[\text{Zn}(\text{IO}_3)_2(\text{IO}_5(\text{OH}))]$ polyanions. (b) The fundamental building units $[\text{Zn}(\text{IO}_3)_2(\text{IO}_5(\text{OH}))]^{4-}$. (c) The 2D $[\text{Zn}(\text{IO}_3)_3(\text{IO}_5(\text{OH}))]^{2-}$ layer. (d) The 3D structure of $\text{K}_2\text{Zn}(\text{IO}_3)_3(\text{IO}_5(\text{OH}))(\text{IO}_2(\text{OH}))(\text{H}_2\text{O})$. Copyright 2023 American Chemical Society.

Fig. 4 (a) $[\text{IO}_3]^-$ pyramid. (b) $[\text{I}_3\text{O}_8]^-$ trimer. (c) The structure of $\text{K}_2\text{Na}(\text{IO}_3)_2(\text{I}_3\text{O}_8)$. how the asymmetric and top-heavy configurations of I–O groups around the Zn^{2+} -centered octahedral units, combined with their varied polymerization modes, create a structurally asymmetric environment that favors polar alignment. Although the $[\text{ZnO}_6]^{10-}$ octahedral unit shows only a small distortion, the asymmetric and top-heavy I–O configurations around it, together, favor the polar alignment of the I–O groups, yielding a strong SHG response of $12 \times \text{KDP}$.

2.3 $\text{K}_2\text{Na}(\text{IO}_3)_2(\text{I}_3\text{O}_8)$

$\text{K}_2\text{Na}(\text{IO}_3)_2(\text{I}_3\text{O}_8)$ was synthesized via a hydrothermal route at 220°C for 4 days.³⁷ The crystal structure can be described as a 3D network (Fig. 4c), where isolated $[\text{I}_3\text{O}_8]^-$ anions and two distinct $[\text{IO}_3]^-$ groups are connected by $1\text{D} \infty[\text{K}(1)\text{O}_5]^{9-}$ chains extending along the *c*-axis and $2\text{D} \infty[\text{K}(2)\text{NaO}_5]^{8-}$ layers within the *bc* plane (Fig. 4a, 2b) The key feature is the well-aligned arrangement and additive superposition of dipole moments from all iodate units within the unit cell, resulting in a macroscopic polarization (Fig. 4d). This dipole superposition creates a macroscopic SHG response of 7.6 times that of KDP.

2.4 $\gamma\text{-Cs}_2\text{I}_4\text{O}_{11}$

$\gamma\text{-Cs}_2\text{I}_4\text{O}_{11}$ was prepared by using two hydrothermal methods: a one-step process with a $\text{H}_2\text{O}/\text{TFA}$ mixed solvent at 220°C , or a

two-step process involving initial synthesis of the $\beta\text{-Cs}_2\text{I}_4\text{O}_{11}$ without TFA, followed by its conversion to the γ phase in TFA solution at 100°C .⁴⁰ The presence of TFA is critical for this conversion, as it acts as a structure-directing properties that promotes the protonation of O atoms in iodate groups, triggering the rearrangement of $[\text{IO}_4]^{3-}$ polyhedra and driving the transformation of *trans*- $[\text{I}_3\text{O}_{10}]^{5-}$ trimers to their *cis*- $[\text{I}_3\text{O}_{10}]^{5-}$. Both β - and γ - $\text{Cs}_2\text{I}_4\text{O}_{11}$ feature a $2\text{D} \infty[\text{I}_3\text{O}_8]^-$ layer, yet they differ in the connectivity and spatial arrangement of their building units, which leads to distinct symmetries and NLO properties. In $\beta\text{-Cs}_2\text{I}_4\text{O}_{11}$, two $[\text{IO}_3]^-$ groups and one $[\text{IO}_4]^{3-}$ unit are corner-shared to form a *trans*- $[\text{I}_3\text{O}_8]^-$ trimer (Fig. 5a). In contrast, the same units in $\gamma\text{-Cs}_2\text{I}_4\text{O}_{11}$ adopt a *cis*- $[\text{I}_3\text{O}_8]^-$ trimeric configuration (Fig. 5b). These trimers extend along the *ab* plane, forming the $2\text{D} \infty[\text{I}_3\text{O}_8]^-$ layer, with Cs^+ cations and remaining isolated $[\text{IO}_3]^-$ anions located at the interlayer space (Fig. 5c). The transformation from the CS β phase to the NCS γ phase is primarily attributed to a geometric rearrangement of the iodate trimers. Specifically, the conversion from a *trans*- to a *cis*-configuration. This structural change enables the dipole moments of the trimers in the γ phase to align along the *b*-axis and add constructively (Fig. 5d), yielding a macroscopic SHG response that is about 5 times that of KDP. This comparison

Fig. 5 2D ${}^2[\text{I}_3\text{O}_8]^-$ layers of β - and γ - $\text{Cs}_2\text{I}_4\text{O}_{11}$ in the ab plane (a, b). Structure of γ - $\text{Cs}_2\text{I}_4\text{O}_{11}$ in the ac plane (c). Local and net dipole moment directions of I–O polyhedra in a whole unit cell (d). Copyright 2023 American Chemical Society.

Fig. 6 (a) ${}^2[\text{Bi}_4\text{O}(\text{SeO}_4)]^{8+}$ layer, the left inset shows $[\text{I}_3\text{O}_{10}]^{5-}$ units and $[\text{IO}_3]^-$ pyramids filling the 18-membered rings. (b) $[\text{Bi}_4\text{O}(\text{I}_3\text{O}_{10})(\text{SeO}_4)]^{3+}$ framework. (c) ${}^2[\text{Bi}_4\text{O}(\text{I}_3\text{O}_{10})]^{5+}$ layer. Copyright 2020 Royal Society of Chemistry.

highlights that controlling the spatial orientation of polar units is a critical structural-design strategy for breaking inversion symmetry and achieving strong SHG performance.

2.5 $\text{Bi}_4\text{O}(\text{I}_3\text{O}_{10})(\text{IO}_3)_3(\text{SeO}_4)$

Colorless block single crystals of $\text{Bi}_4\text{O}(\text{I}_3\text{O}_{10})(\text{IO}_3)_3(\text{SeO}_4)$ were obtained via a hydrothermal reaction at 230 °C for 3 days in a highly acidic medium.³⁹ $\text{Bi}_4\text{O}(\text{I}_3\text{O}_{10})(\text{IO}_3)_3(\text{SeO}_4)$ crystallizes in the polar space group $R3c$, featuring a unique 3D framework formed by the connection of various anionic units (**Fig. 6b**). In this structure, each $[\text{SeO}_4]^{2-}$ tetrahedron coordinates to three Bi atoms through its O atoms, forming 18-membered rings (MRs) that extend in the ab plane and interconnect to form a continuous 2D ${}^2[\text{Bi}_4\text{O}(\text{SeO}_4)]^{8+}$ layer. These ring-shaped channels are filled with pinwheel-shaped $[\text{I}_3\text{O}_{10}]^{5-}$ units and $[\text{IO}_3]^-$ pyramids, which together with the rings form a 2D layered structure in the ab plane (**Fig. 6a**). Meanwhile, the $[\text{I}_3\text{O}_{10}]^{5-}$ units connect through Bi atoms, forming a second type of layer ${}^2[\text{Bi}_4\text{O}(\text{I}_3\text{O}_{10})]^{5+}$ (**Fig. 6c**). These two different layered features are stacked along the c -axis and linked by shared O atoms, ultimately forming the overall 3D framework. The asymmetric polyiodate groups, with their SCALPs, disrupt CS and drive crystallization in the polar space group $R3c$, which exhibits

enhanced polarization and SHG response of approximately 1.1 × KDP.

2.6 $\text{Ba}_4\text{Ag}_5(\text{IO}_3)_6(\text{I}_3\text{O}_8)_3(\text{I}_4\text{O}_{11})_2$

Colorless plate crystals of $\text{Ba}_4\text{Ag}_5(\text{IO}_3)_6(\text{I}_3\text{O}_8)_3(\text{I}_4\text{O}_{11})_2$ were synthesized via a hydrothermal reaction at 230 °C for 3 days.⁵⁰ $\text{Ba}_4\text{Ag}_5(\text{IO}_3)_6(\text{I}_3\text{O}_8)_3(\text{I}_4\text{O}_{11})_2$ crystallizes in the polar space group $Pnc2_1$. $[\text{AgO}_n]$ polyhedra exist in forms such as $[\text{AgO}_6]^{11-}$ and $[\text{AgO}_4]^{7-}$. By connecting $[\text{I}_3\text{O}_8]^-$ trimers and isolated $[\text{IO}_3]^-$ units, they assemble into a 2D layer of ${}^2[\text{Ag}_5(\text{I}_3\text{O}_8)_3(\text{IO}_3)_4]^{2-}$ anions parallel to the ac plane (**Fig. 7b**). $[\text{BaO}_n]$ polyhedra comprise $[\text{BaO}_8]^{14-}$ and $[\text{BaO}_7]^{12-}$ polyhedra. These interact with $[\text{I}_4\text{O}_{11}]^{2-}$ and $[\text{I}_3\text{O}_8]^-$, and $[\text{IO}_3]^-$ anions. From a holistic structural perspective, the 2D ${}^2[\text{Ag}_5(\text{I}_3\text{O}_8)_3(\text{IO}_3)_4]^{2-}$ layers are embedded and stabilized within the 3D $[\text{Ba}_4(\text{IO}_3)_6(\text{I}_3\text{O}_8)_3(\text{I}_4\text{O}_{11})_2]^{5-}$ framework (**Fig. 7c**). Multiple iodate anions (isolated $[\text{IO}_3]^-$, $[\text{I}_3\text{O}_8]^-$ trimers, and $[\text{I}_4\text{O}_{11}]^{2-}$ tetramer) (**Fig. 7a**) and $[\text{AgO}_n]$ polyhedra synergistically enhance the macroscopic SHG response, exhibiting moderate SHG performance of 2.5 times that of KDP.

2.7 $\text{REI}_5\text{O}_{14}$ ($\text{RE} = \text{Y, Eu, Gd, Tb, Dy, Ho, Er, Tm, and Yb}$)

The series of rare-earth polyiodates $\text{REI}_5\text{O}_{14}$ ($\text{RE} = \text{Eu, Er, Tm, Yb}$) was synthesized via H_3PO_4 -mediated hydrothermal reactions, with $\text{EuI}_5\text{O}_{14}$ obtained at 230 °C and the other members

Fig. 7 (a) $[\text{I}_3\text{O}_8]^-$ trimer and $[\text{I}_4\text{O}_{11}]^{2-}$ tetramer. (b) 2D ${}^2[\text{Ag}_5(\text{I}_3\text{O}_8)_3(\text{IO}_3)_4]^{2-}$ anionic layer. (c) The structure of $\text{Ba}_4\text{Ag}_5(\text{IO}_3)_6(\text{I}_3\text{O}_8)_3(\text{I}_4\text{O}_{11})_2$ along the c direction. Copyright 2022 Royal Society of Chemistry.

($RE = Tm, Yb$) formed at 180 °C. The family of REI_5O_{14} compounds crystallizes in two distinct NCS polar space groups (Fig. 8a).^{42,43} For $RE = Eu, Gd$, and Y , the crystals crystallize in the polar space group Cm . In these structures, the I(1) atom exhibits

half-occupancy disorder due to its special position on m plane. One $[(1)O_4]^{3-}$ unit, two $[(2)O_4]^{3-}$ units, and two $[(3)O_3]^{3-}$ units are bridged through O atoms, assembling into a novel semicircular $[I_5O_{14}]^{3-}$ polyanion (Fig. 8c). These polyanions are

further interconnected through $[REO_8]^{13-}$ polyhedra, forming 2D ${}^2_{\infty}[RE_5O_{14}]$ layers. The overall crystal structure is constructed by the stacking of these layers along the *b*-axis (Fig. 8b). In contrast, for *RE* = Er, Tm, and Yb, the compounds crystallize in the polar NCS space group *Pmn*2₁. In these structures, all the I atom sites are fully occupied without positional disorder. One $[I(1)O_4]^{3-}$ unit bridges two $[I(2)O_3]^-$ groups to form a chain ${}^1_{\infty}[I_3O_8]^-$ polyanion. Two additional $[I(3)O_3]^-$ groups are attached to this core via weak I–O interactions, resulting in a $[(I_3O_8)(IO_3)_2]^{3-}$ polyanion (Fig. 8d). These polyanions are interconnected through $[REO_8]^{13-}$ polyhedra, forming 2D ${}^2_{\infty}[RE_5O_{14}]$ layers that stack along the *a*-axis to generate the overall crystal framework (Fig. 8e). Among these compounds, the maximum SHG response reaches up to 15 × KDP, which primarily originates from the cooperative alignment of local dipole moments within the anionic units. In contrast, ErI_5O_{14} exhibits a significantly weaker SHG efficiency of only 0.7 × KDP, which can be attributed to the competitive *d*–*d* and *f*–*f* electronic transitions of Er^{3+} ions that cause absorption of both the input and output light.

2.8 $[o-C_5H_4NHOH]_2[I_7O_{18}(OH)] \cdot 3H_2O$

$[o-C_5H_4NHOH]_2[I_7O_{18}(OH)] \cdot 3H_2O$ is isolated via slow evaporation of its aqueous precursor solution at room temperature. $[o-C_5H_4NHOH]_2[I_7O_{18}(OH)] \cdot 3H_2O$ crystallizes in the polar space group *Ia*.⁴⁴ Its structure features a novel 1D branched polyiodate chain ${}^1_{\infty}[I_7O_{18}(OH)]^{2-}$, extending along the *c*-axis. This anion consists of seven distinct I atoms, the $[I(1)O_3(OH)]^{2-}$, $[I(2)O_4]^{3-}$, $[I(3)O_4]^{3-}$, and $[I(4)O_3]^-$ units are interconnected through corner-sharing O atoms to form $[I_4O_{11}(OH)]^{3-}$ tetramer (Fig. 9a). Simultaneously, the $[I(5)O_4]^{3-}$, $[I(6)O_4]^{3-}$, and $[I(7)O_3]^-$ units are linked via corner-sharing O atoms, resulting in a trimer $[I_3O_9]^{3-}$ (Fig. 9b). Adjacent

$[I_4O_{11}(OH)]^{3-}$ tetramers are bridged through $I(1)–O(10)–I(4)$ linkage, forming a 1D $[I_4O_{10}(OH)]^-$ main chain. The $[I_3O_9]^{3-}$ trimers are subsequently grafted onto this main chain via $I(4)–O(11)–I(5)$ bridges, collectively constructing the branched polyiodate chain ${}^1_{\infty}[I_7O_{18}(OH)]^{2-}$ (Fig. 9c). The 1D chains, aligned along the *c*-axis, are interconnected with lattice water molecules via hydrogen bonds, forming a 2D supramolecular layer. The protonated $(o-C_5H_4NHOH)^+$ cations occupy the interlayer spaces, not only balancing the overall charge but also engaging in extensive hydrogen-bonding interactions with the ${}^1_{\infty}[I_7O_{18}(OH)]^{2-}$ chains. These hydrogen bonds serve as the primary interlayer interactions, further stabilizing the three-dimensional supramolecular framework (Fig. 9d). The compound exhibits an excellent SHG response (8.5 × KDP), which is attributed to the well-ordered alignment of the highly polarizable $[IO_3]^-$ and $[IO_4]^{3-}$ units within the ${}^1_{\infty}[I_7O_{18}(OH)]^{2-}$ polyiodate chain.

3. Aliovalent substitution

To further enhance the SHG performance and enrich the structural diversity of materials, our group have applied the well-established aliovalent substitution strategy to the iodate system, successfully developing a series of new NLO crystals with improved properties. This approach starts with a known parent compound that already exhibits a strong SHG response, and then introduces co-substitution at two different anionic sites, or simultaneously at one cationic and one anionic site. Such substitutions effectively optimize the comprehensive performance. This section systematically discusses the key roles of vacancy-site, single-site, dual-site, and multi-site aliovalent substitution in the design of novel NLO crystals. Compounds with notable SHG responses obtained through this strategy are summarized in Table 2.

Table 2. Optical properties of iodates synthesized via aliovalent substitution.

3.1 LiGa(IO₃)₄

Single crystals of LiGa(IO₃)₄ were obtained via a hydrothermal reaction at 220 °C for 3 days.⁵³ Based on α-LiIO₃ (Fig. 10a), a new material, LiGa(IO₃)₄, was successfully synthesized through partial substitution of Li⁺ ions by Ga³⁺ ions (Fig. 10c). In the crystal structure, Ga atoms coordinate with six $[IO_3]^-$ groups, forming isolated 0D $[Ga(IO_3)_6]^{3-}$ units. $[Ga(IO_3)_6]^{3-}$ units further extend along the *ab* plane, connecting into a 2D layer ${}^2_{\infty}[Ga(IO_3)_4]^-$, while Li⁺ ions occupy the interlayer spaces, serving to balance charge (Fig. 10b). The partial substitution of Li⁺ (0.76 Å) by the smaller Ga³⁺ (0.62 Å) cation is accompanied by a contraction of the unit cell volume from α-LiIO₃ to LiGa(IO₃)₄. With the number of $[IO_3]^-$ groups per unit cell identical, the

density of polar $[IO_3]^-$ groups increases from 0.0148 Å⁻³ in α-LiIO₃ to 0.0155 Å⁻³ in LiGa(IO₃)₄. As a result, the compound exhibits a strong SHG response of approximately 14 × KDP. Aliovalent substitution proves effective in tuning iodate structures and boosting NLO performance.

3.2 LiMg(IO₃)₃

Colorless prismatic crystals of LiMg(IO₃)₃ (*P6*₃) were synthesized via a hydrothermal reaction at 230 °C for 3 days in a dilute HCl medium.⁵⁴ LiMg(IO₃)₃ can be also considered to be formed by substituting Ti⁴⁺ ions with Mg²⁺ ions in the parent compound Li₂Ti(IO₃)₆. In the structure of Li₂Ti(IO₃)₆ (*P6*₃), Li⁺ and Ti⁴⁺ occupy the 2b and 2a special sites, respectively. When Mg²⁺ replaces Ti⁴⁺, a Wyckoff site exchange occurs: Mg²⁺ occupies the original

Li⁺ site and forms a [MgO₆]¹⁰⁻ octahedron. This alters the bonding pattern with the [IO₃]⁻ group, enhancing local

asymmetric polarization. Concurrently, Li⁺ migrates to the higher-symmetry 2a site, acting as a counter-cation filling the 1D channels within the 3D framework (Fig. 11a, 11b). Mg²⁺ substitution for Ti⁴⁺ not only induces positional exchange but also increases the stacking density of [IO₃]⁻ groups, exhibiting strong SHG response (24 × KDP) and thereby enhancing effective SHG output.

3.3 CsVO₂F(IO₃)

CsVO₂F(IO₃) crystals were hydrothermally synthesized at 160 °C for 72 hours.⁵⁵ Through a dual-site aliovalent substitution strategy ($\text{Mo}^{6+} + \text{O}^{2-} \rightarrow \text{V}^{5+} + \text{F}^-$), the [MoO₆]⁶⁻ octahedra in the parent compound CsMoO₃(IO₃) (Fig. 12a) were replaced by [VO₅F]⁶⁻ octahedra, preserving the original framework structure. In the resulting architecture, each [VO₅F]⁶⁻ octahedra coordinates with two [IO₃]⁻ groups, forming a *cis*-[VO₃F(IO₃)₂]⁴⁻ anionic unit. These units extend along the *c*-axis through shared O atoms, constructing a 1D chain structure with [IO₃]⁻ groups distributed on both sides. Adjacent chains are interconnected via [IO₃]⁻ groups, generating an extended structure with channel

features, while Cs⁺ cations reside within the interchain voids, serving to balance charge and stabilize the overall structure (Fig. 12b). CsVO₂F(IO₃) exhibits remarkable NLO properties, demonstrating a strong SHG response of 1.1 times that of KTP (absorption edge: 525 nm, $E_g = 2.36$ eV), comparable to that of the parent compound CsMoO₃(IO₃) (~1.2 × KTP). Theoretical analysis reveals that the ordered alignment and distinctive electronic structure of the *cis*-[VO₃F(IO₃)₂]⁴⁻ units play a critical role in achieving the enhanced SHG efficiency.

3.4 α/β -Ba₂[GaF₄(IO₃)₂](IO₃)

The formation of two distinct polymorphs (α/β -Ba₂GaF₄(IO₃)₂) under identical hydrothermal conditions is attributed to differences in the initial Ga³⁺ concentration, which influences the crystallization kinetics and the resulting arrangement of the anionic building units.⁵⁶ Building upon the previously reported α - and β -Ba₂[VO₂F₂(IO₃)₂] compounds by Poeppelmeier's group,⁵⁸ the corresponding α - and β -Ba₂[GaF₄(IO₃)₂] phases were successfully synthesized via a three-site substitution strategy ($\text{V}^{5+} + 2\text{O}^{2-} \rightarrow \text{Ga}^{3+} + 2\text{F}^-$) (Fig. 12a-12d). All four

Fig. 12 Schematic atomic structure from $\text{CsMoO}_3(\text{IO}_3)$ (a) to $\text{CsVO}_2\text{F}(\text{IO}_3)_2$ (b) via aliovalent substitution routes. Copyright 2020 Wiley-VCH.

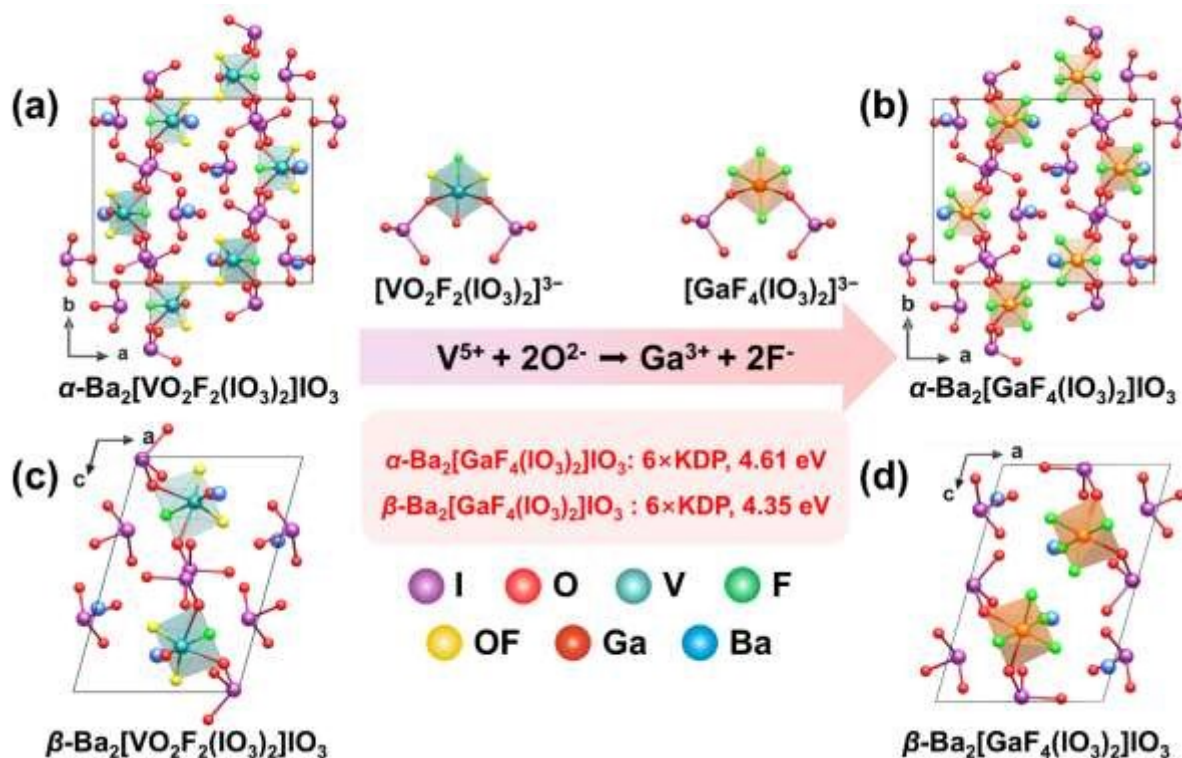

Fig. 13 Schematic atomic structure from $\alpha/\beta\text{-Ba}_2[\text{VO}_2\text{F}_2(\text{IO}_3)_2]\text{IO}_3$ (a) to $\alpha/\beta\text{-Ba}_2[\text{GaF}_4(\text{IO}_3)_2]\text{IO}_3$ (b) via aliovalent substitution routes. Copyright 2018 Wiley-VCH and 2018 American Chemical Society.

compounds consist of 0D *cis*- $[\text{MO}_x\text{F}_{4-x}(\text{IO}_3)_2]^{3-}$ ($x = 0, 2$) anionic units, isolated $[\text{IO}_3]^-$ groups, and Ba^{2+} counterions. The structural distinction between the α - and β -phases originates from different packing arrangements of the anionic units, resulting in crystallization in the polar space groups $Pna2_1$ and $P2_1$, respectively. Although the highly distorted $[\text{VO}_4\text{F}_2]^{5-}$ ($\Delta d = 1.20$ and 1.21) octahedra are replaced by less distorted $[\text{GaO}_2\text{F}_4]^{5-}$ ($\Delta d = 0.32$ and 0.44) octahedra, the polar topological

characteristics of the framework are preserved. Consequently, the SHG responses of α - and β - $\text{Ba}_2[\text{GaF}_4(\text{IO}_3)_2]$ are 6 times that of KDP, slightly lower than that of the parent compounds ($9 \times$ KDP). In contrast, the band gaps significantly increase to 4.61 eV and 4.35 eV, respectively, substantially wider than those of the parent phases (2.55 eV and 2.59 eV). Aliovalent substitution offers a rational synthetic strategy to effectively tune the structural dimensionality, polar unit density, and electronic

configuration of iodates through precise site-specific replacement, thereby yielding crystalline materials with excellent NLO performance.

4. Fluorination substitution

Incorporating I–F bonds into iodates represents an effective strategy for tailoring their optical properties. The high electronegativity of the F atom helps to widen the optical band gap, while the resulting fluoro-iodate anions, such as $[\text{IO}_3\text{F}]^{2-}$ seesaw,^{59–62} $[\text{IO}_2\text{F}_2]^-$ seesaw,^{63,64} and $[\text{IOF}_4]^-$ square pyramid,⁶⁵

typically exhibit large polarizability anisotropy, which is conducive to enhancing the materials' SHG response. These anions can further polymerize via O bridges to form various aggregated structures ($[\text{I}_2\text{O}_5\text{F}_2]^{2-}$ dimer, $[\text{I}_2\text{O}_5\text{F}]^-$ dimer, and $[\text{I}_3\text{O}_7\text{F}_3]^{2-}$ trimer).^{59,66} To date, the reported family of fluoroiodates remains relatively limited, with only compounds containing $[\text{IO}_3\text{F}]^{2-}$, $[\text{IO}_2\text{F}_2]^-$, and $[\text{I}_3\text{O}_7\text{F}_3]^{2-}$ confirmed to exhibit SHG activity. This section systematically discusses the structural characteristics and performance of NCS iodates containing these three types of fluoroiodate anionic units. Fluoroiodates with SHG activity are summarized in **Table 3**.

4.1 $[\text{GaF}(\text{H}_2\text{O})][\text{IO}_3\text{F}]$

Wedge-shaped prismatic crystals of $[\text{GaF}(\text{H}_2\text{O})][\text{IO}_3\text{F}]$ were synthesized via a hydrothermal reaction at 230 °C for 67 hours in an HF-containing medium.⁶⁷ $[\text{GaF}(\text{H}_2\text{O})][\text{IO}_3\text{F}]$ (*Pca2*₁) features a salt-inclusion like structure, built from 1D zigzag $[\text{GaF}(\text{H}_2\text{O})]^{2+}$ chains and polar $[\text{IO}_3\text{F}]^{2-}$ anions (**Fig. 14a**). These components assemble into a 2D layer $[\text{GaF}(\text{H}_2\text{O})][\text{IO}_3\text{F}]$ in the *bc* plane through Ga–O/F coordination bonds (**Fig. 14b**), with

subsequent –ABAB– stacking along the *a*-axis, yielding a 3D framework (**Fig. 14c**). Crucially, the $[\text{IO}_3\text{F}]^{2-}$ units are aligned unidirectionally along the *c*-axis, leading to constructive superposition of their local dipole moments. This configuration generates strong macroscopic polarity, which results in a remarkable SHG response of 10 × KDP. Moreover, the presence of fluorine atoms contributes to a wide optical bandgap of 4.34 eV, showcasing a valuable synergy between strong NLO activity and high transparency in the high-energy spectral region.

Copyright 2022 Royal Society of Chemistry and 2021 American Chemical Society.

4.2 A₂MO₂F₃(IO₂F₂) (A = Cs, Rb; M = Mo, W)

The series of isostructural compounds A₂MO₂F₃(IO₂F₂) (A = Cs, Rb; M = Mo, W) was synthesized under similar mild hydrothermal conditions (220–230 °C, 4 days), wherein hydrofluoric acid served as both a fluorinating agent and a crucial mineralizer to form the characteristic fluorinated anionic units simultaneously.^{69,70} These compounds all crystallize in the NCS polar space group *Cmc*2₁. Their structures include OD [M(O₂F₃)(IO₂F₂)]₂⁻ polyanions (M = Mo, W), formed by combining fluorinated d⁰ transition metal [MO₃F₃]³⁻ groups with fluoroiodate [IO₂F₂]⁻ units through coordination bonds (Fig. 15a, 15b). In the crystal lattice, these [M(O₂F₃)(IO₂F₂)]₂⁻ polyanions align along the *c*-axis with a consistent polar orientation, while alkali metal cations (Cs⁺/Rb⁺) occupy interstitial sites to maintain charge neutrality (Fig. 15c). The strong SHG response of these materials results from the combined structure and the aligned arrangement of the [M(O₂F₃)(IO₂F₂)]₂⁻ anions. The [MO₃F₃]³⁻ octahedra exhibit significant C₄-type angular distortion, causing the M⁶⁺ cations to shift toward terminal O atoms and establishing a fixed local polarization direction. Meanwhile, the I⁵⁺ centers in the [IO₂F₂]⁻ units, which possess SCALPs, create inherent asymmetry that further influences and amplifies the distortion direction of nearby [MO₃F₃]³⁻ octahedra. Through this cooperative interaction, the dipole moments of all structural units add along the crystallographic *c*-axis, ultimately generating a strong NLO response at the macroscopic level (Fig. 15d).

4.3 M₄O(IO₃)₃(I₃O₇F₃)BF₄ (M = Pb, Sr)

Single crystals of M₄O(IO₃)₃(I₃O₇F₃)BF₄ (M = Pb, Sr) were synthesized via low-temperature solid-state reactions at 240 °C for 3 days.⁶⁶ M₄O(IO₃)₃(I₃O₇F₃)BF₄ crystallizes in the NCS trigonal space group *R3c*, exhibiting a structurally complex 3D framework assembled from four distinct building units: conventional [IO₃]⁻ and [BF₄]⁻ anions, [M₄O]⁶⁺ tetrahedra, and a previously unreported windmill-shaped [I₃O₇F₃]²⁻ fluoroiodate trimer (Fig. 16a–16d). Structural analysis reveals that [BF₄]⁻ tetrahedra and [M₄O]⁶⁺ tetrahedra interconnect via M–F and M–O bonds to form a 2D anionic [M₄O(BF₄)]⁸⁺ layer, characterized by 18-MRs. The [IO₃]⁻ and [I₃O₇F₃]²⁻ units occupy the interstitial spaces within these rings (Fig. 16e–16f). These hybrid layers subsequently stack along the *c*-axis and are interconnected via Pb–O bonds, forming a 3D network (Fig. 16g). Detailed polarization analysis indicates that the local dipole moments associated with the [IO₃]⁻ and [I₃O₇F₃]²⁻ units exhibit superposition along the crystallographic *c*-axis, while undergoing substantial mutual cancellation within the *ab* plane due to their antiparallel arrangements. This anisotropic dipole alignment generates a net macroscopic polarization vector oriented predominantly parallel to the *c*-axis. Consequently, this NCS polar structure enables excellent comprehensive NLO performance, including strong SHG responses (4 and 3.5 × KDP, respectively) and wide optical bandgaps (3.73 and 4.19 eV). In contrast to Bi₄O(I₃O₁₀)(IO₃)₃(SeO₄) (In Section 2.5), which crystallizes in the same space group *R3c* but exhibits a significantly weaker SHG response of only 1.1 × KDP and narrower optical bandgap 3.79 eV. The superior comprehensive performance of M₄O(IO₃)₃(I₃O₇F₃)BF₄ can be attributed to three

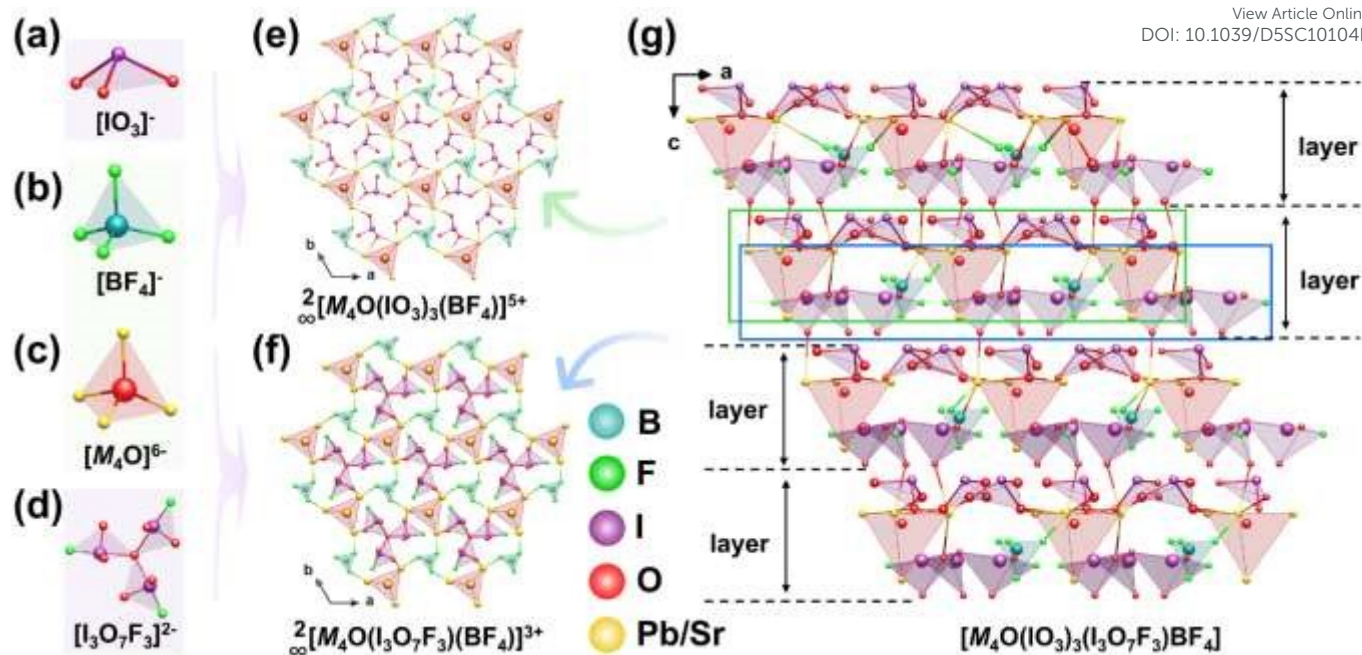

Fig. 16 (a) [IO₃]⁻ polyhedral. (b) [BF₄]⁻ polyhedral. (c) [M₄O]⁶⁻ polyhedral. (d) [I₃O₇F₃]²⁻ polyhedral. (e) [M₄O(IO₃)₃(BF₄)]⁵⁺. [M₄O(I₃O₇F₃)(BF₄)]³⁺. (g) 3D structure of the M₄O(IO₃)₃(I₃O₇F₃)BF₄ (A = Rb, Cs; M = Mo, W). Copyright 2021 American Chemical Society.

key factors: (i) cation substitution (Pb²⁺ to Bi³⁺) modulates the electronic contribution to SHG, with Pb²⁺ showing a slight advantage over Bi³⁺ due to its more favorable lone-pair activity; (ii) tetrahedral anion substitution ([BF₄]⁻ to [SeO₄]²⁻) preserves the overall framework topology; and (iii) most importantly, fluorine modification plays a dual critical role: it widens the band gap, while simultaneously contributing to the strong SHG response through the formation of asymmetric [I₃O₇F₃]²⁻ units. The SHG enhancement underscores the essential role of fluorine in achieving high-performance NLO materials.

5. Combinations of the iodate groups with the π-conjugated units

π-Conjugated structural units are pivotal building blocks in the design of functional materials, and their essential characteristics can be summarized in two aspects: (i) their planar or nearly planar geometry; (ii) the presence of π-orbital electron clouds oriented

perpendicular to the molecular plane. Due to electron delocalization, π-conjugated units exhibit higher hyperpolarizabilities and more pronounced polarizability anisotropy than non-conjugated structural moieties. Introducing π-conjugated groups into crystalline materials allows the synergistic exploitation of their electronic properties, enabling the design and synthesis of novel iodates with both strong SHG and outstanding birefringence. Representative [BO₃]³⁻, [CO₃]²⁻, and [NO₃]⁻ all exhibit favorable optical properties, owing to their wide band gaps, moderate birefringence, and good chemical stability.⁷⁴⁻⁷⁶ In recent years, with advances in research on organic-inorganic hybrid materials, the focus has expanded from traditional inorganic anions to organic π-conjugated cationic systems. Due to their larger conjugated systems and tunable molecular structures, these organic cations generally exhibit more pronounced polarizability anisotropy and hyperpolarizabilities compared to inorganic anions. In this section, we discuss five iodates containing representative π-conjugated units, while additional related compounds are summarized in **Table 4**.

5.1 $\text{Na}_2[\text{B}_4\text{IO}_9](\text{IO}_3)$

$\text{Na}_2[\text{B}_4\text{IO}_9](\text{IO}_3)$, which crystallizes in the polar space group Cc with a unique 2D anionic layer framework, was synthesized via a boric acid melting reaction at 230 °C for 5 days.⁷⁷ The fundamental building block consists of a $[\text{B}_4\text{IO}_{11}]^{5-}$ cluster (Fig. 17a), formed by three planar π -conjugated $[\text{BO}_3]^{3-}$ groups, one $[\text{BO}_4]^{5-}$ tetrahedron, and one $[\text{IO}_3]^-$ trigonal pyramid. The borate groups form $[\text{B}_3\text{O}_7]^{5-}$ clusters, which are further bridged by additional $[\text{BO}_3]^{3-}$ groups into a 2D layer, with $[\text{IO}_3]^-$ groups hanging on the same side of the layer via I-O-B bridges, forming a novel ${}^2_{\infty}[\text{B}_4\text{IO}_9]^-$ layer with distinctive 18-MRs (Fig. 17b, 17c), creating a highly polarized structural configuration. The layers stack parallel along the c -axis, with the interlayer spaces occupied by Na^+ cations and additional isolated $[\text{IO}_3]^-$ groups (Fig. 17d). This well-designed framework enables synergistic alignment of two types of nonlinearly active units ($[\text{BO}_3]^{3-}$ and $[\text{IO}_3]^-$), leading to a remarkable SHG response (7.8× KDP) and an exceptionally large birefringence (0.295 at 546 nm).

5.2 $\text{Be}_2(\text{BO}_3)(\text{IO}_3)$

$\text{Be}_2(\text{BO}_3)(\text{IO}_3)$ (BBIO) was obtained via a hydrothermal reaction at 200 °C for 5 days. It adopts a KBBF-type 2D layered structure (Fig.

18a), featuring a distinctive $[\text{Be}_2(\text{BO}_3)(\text{IO}_3)]$ composite layer composed of alternating ${}^2_{\infty}[\text{Be}_2\text{BO}_5]^{3-}$ layers and $[\text{IO}_3]^-$ units.⁷⁸ The ${}^2_{\infty}[\text{Be}_2\text{BO}_5]^{3-}$ layer maintains the fundamental connectivity of the ${}^2_{\infty}[\text{Be}_2\text{BO}_3\text{F}_2]^-$ layer found in KBBF (R32) (Fig. 18d), and the ordered alignment of the $[\text{BO}_3]^{3-}$ groups allows BBIO to inherit its inherent NLO capability. Unlike the ${}^2_{\infty}[\text{Be}_2\text{BO}_3\text{F}_2]^-$ layer in KBBF, however, the ${}^2_{\infty}[\text{Be}_2\text{BO}_5]^{3-}$ layer in BBIO has a distinct corrugated morphology. This structural distortion not only creates new opportunities for crystal engineering but also generates undulating interlayer spaces that serve as crucial environments for embedding and arranging the $[\text{IO}_3]^-$ units in an ordered manner. The $[\text{IO}_3]^-$ groups connect to the corrugated ${}^2_{\infty}[\text{Be}_2\text{BO}_5]^{3-}$ layer through the terminal O atoms of the $[\text{BeO}_4]^{6-}$ tetrahedra (Fig. 18b). The folded geometry of this polar borate layer further ensures a consistent polar orientation among all the $[\text{IO}_3]^-$ units (Fig. 18c). At the same time, the corrugated structure permits the dipole moments of the $[\text{BeO}_4]^{6-}$ tetrahedra to align coherently along the negative c -axis, a sharp contrast to the mutually canceled dipoles of the $[\text{BeO}_3\text{F}]^{5-}$ units in KBBF. As a result, the overall dipole moment from both the $[\text{BeO}_4]^{6-}$ tetrahedra and the $[\text{IO}_3]^-$ groups adds constructively along the negative c direction, producing a strong SHG response approximately 7.2 times that of the KDP.

5.3 $\text{Sc}(\text{IO}_3)_2(\text{NO}_3)$

Colorless block crystals of $\text{Sc}(\text{IO}_3)_2(\text{NO}_3)$ were obtained via a hydrothermal reaction at 160 °C for 3 days in 50% HNO_3 medium. $[\text{Sc}(\text{IO}_3)_2(\text{NO}_3)]$ features a distinctive layered framework, in which honeycomb-type ${}^2_{\infty}[\text{Sc}(\text{IO}_3)_2]$ layers and 2D ${}^2_{\infty}[\text{NO}_3]^-$ layers are stacked

alternately along the c -axis in -ABAB- sequence.⁷⁹ Within the structure, each $[\text{ScO}_6]^{9-}$ octahedron is connected to six surrounding $[\text{IO}_3]^-$ units through shared O atoms, generating a 2D honeycomb-like network ${}^2_{\infty}[\text{Sc}(\text{IO}_3)_2]$ in the ab plane (Fig. 19a-19c). Notably, within the ${}^2_{\infty}[\text{Sc}(\text{IO}_3)_2]^+$ layer, adjacent $[\text{IO}_3]^-$ groups adopt a face-to-face

arrangement across inter-layer gaps, while all $[\text{IO}_3]^-$ units are aligned in a uniform orientation (Fig. 19d). These isolated $[\text{NO}_3]^-$ units are well aligned within the quasi-2D layer (Fig. 19e). This configuration promotes the ordered superposition of anisotropic polarizability tensors and thus contributes to a potentially large birefringence. As a result, the compound exhibits one of the strongest SHG responses among nitrate-based materials ($4 \times \text{KDP}$) and a remarkable birefringence of 0.348 at 546 nm, representing the largest value reported for inorganic oxide optical crystals in its class. The strategic fusion of functional groups, each contributing distinct optical advantages, establishes a powerful design paradigm for the next generation of high-performance nonlinear optical crystals.

5.4 $[\text{C}(\text{NH}_2)_3]_2\text{Mo}_2\text{O}_5(\text{IO}_3)_4 \cdot 2\text{H}_2\text{O}$

$[\text{C}(\text{NH}_2)_3]_2\text{Mo}_2\text{O}_5(\text{IO}_3)_4 \cdot 2\text{H}_2\text{O}$ was synthesized under mild hydrothermal conditions at 85 °C for 4 days. It crystallizes in the polar orthorhombic space group $Pna2_1$.⁸⁰ Its structure features a novel boat-shaped $[\text{Mo}_2\text{O}_5(\text{IO}_3)_4]^{2-}$ polyanionic cluster (Fig. 20b), constructed from two corner-shared $[\text{MoO}_6]^{6-}$ octahedra and four $[\text{IO}_3]^-$ units. Two $[\text{C}(\text{NH}_2)_3]^+$ cations serve not only as charge-balanced counterions but also, through their extensive N–H···O hydrogen-bonding network, act as structural directing agents that organize multiple $[\text{Mo}_2\text{O}_5(\text{IO}_3)_4]^{2-}$ clusters around them (Fig. 20a, 20c). More importantly, the planar triangular geometry of the $[\text{C}(\text{NH}_2)_3]^+$ cations, combined with steric hindrance and hydrogen-bonding guidance,

causes these boat-shaped clusters to adopt a highly parallel alignment. This parallel arrangement allows the local dipole moments from the polar $[\text{IO}_3]^-$ units and distorted $[\text{MoO}_6]^{6-}$ octahedra within each cluster to add coherently along the *c*-axis, resulting in strong macroscopic polarization. Through this organic cation-templated, ordered assembly of functional inorganic clusters, the material shows excellent nonlinear optical response, with SHG about 5 times that of KDP. This work demonstrates how the shape and hydrogen-bonding ability of organic cations can be used to precisely control the spatial arrangement of inorganic clusters, improving overall optical properties.

5.5 $(\text{C}_3\text{H}_7\text{N}_6)(\text{IO}_3)$

Colorless rod-like crystals were obtained via a low-temperature (85 °C) solution reaction in a $\text{H}_3\text{PO}_4\text{-H}_2\text{O}$ mixed medium.⁸¹ The crystalline framework of $(\text{C}_3\text{H}_7\text{N}_6)(\text{IO}_3)$ demonstrates a rational strategy for achieving symmetry breaking through the introduction of an expanded π -conjugated cation. Whereas the parent compound $\text{C}(\text{NH}_2)_3(\text{IO}_3)$ contains a C_3 -symmetric $[\text{C}(\text{NH}_2)_3]^+$ cation forming a CS 3D network via hydrogen bonding (Fig. 21a-21c), the protonated melamine cation $[\text{C}_3\text{H}_7\text{N}_6]^+$ exhibits a reduced symmetry from C_3 to C_2 . This molecular-level symmetry reduction triggers a fundamental reconstruction of the hydrogen-bonding pattern: instead of forming a symmetrically compensated hydrogen-bond network, the $[\text{IO}_3]^-$ anions establish directional $\text{N-H}\cdots\text{O}$ hydrogen bonds with specifically oriented N-H groups, achieving an aligned arrangement within the crystal lattice (Fig. 21d-21f). The resulting hydrogen-bond reconstruction transforms local polar units into a macroscopically ordered architecture, ultimately accomplishing the transition from a CS to an NCS crystal (*Cc*) and generating a strong SHG response ($6.7 \times \text{KDP}$) and a moderate birefringence (0.16 at 550 nm). This integrated strategy, combining asymmetric planar motifs (or chiral organic) units, constitutes a systematic and effective paradigm for

the rational design of NCS iodate materials. The continued development of this molecular-level engineering approach is expected to unlock further structural and functional diversity. By precisely tailoring chiral environments, hydrogen-bonding networks, and spatial organization, future research can aim to effectively enhance the probability of NCS crystallization while optimizing the overall optical performance.

6. Synergy effects of the iodate groups with the tetrahedral functional units

Tetrahedral anionic groups such as $[\text{PO}_4]^{3-}$, $[\text{SO}_4]^{2-}$, and $[\text{SeO}_4]^{2-}$ represent an important class of SHG-active units. Despite their relatively low hyperpolarizability and small polarizability anisotropy, their incorporation into iodate systems enables effective synergistic modulation of structural and functional properties. These tetrahedral groups not only enrich the structural chemistry of iodates via their rigid topology and diverse coordination modes but also significantly widen the optical band gap of the resultant compounds, owing to their high bond energy and the presence of highly electronegative atoms. In contrast, iodate units themselves exhibit large hyperpolarizability and pronounced polarizability anisotropy, yet their band gaps are generally narrower. Therefore, the combination of tetrahedral anions with iodate groups creates a complementary system in which the large SHG coefficients and high polarizability anisotropy of iodates are synergistically coupled with the wide band gaps and structural directing capability of the tetrahedral units, leading to optimized overall NLO performance. This section presents representative examples of iodates containing tetrahedral $[\text{PO}_4]^{3-}$, $[\text{SO}_4]^{2-}$, and $[\text{SeO}_4]^{2-}$ units, while other SHG-active iodates containing tetrahedral units are summarized in Table 5.

6.1 Nb₂O₃(IO₃)₂(SO₄)

Nb₂O₃(IO₃)₂(SO₄) was obtained through a two-step hydrothermal synthesis, using the intermediate Nb₂O₄(SO₄) (prepared at 230 °C) as the precursor in a subsequent reaction at 210 °C.⁸⁹ In the structure of Nb₂O₃(IO₃)₂(SO₄), two Nb-centered octahedra share O atoms to form [Nb₂O₉]⁸⁻ unit. (Fig. 22a). [IO₃]⁻ groups are attached to both sides of these chains, collectively constituting the [Nb₂O₇(IO₃)₂]⁶⁻ structural units that extend along the chain direction (Fig. 22b). These chains are further interconnected via bridging O atoms, resulting in a 2D [∞][Nb₂O₃(IO₃)₂]²⁺ layer (Fig. 22c). Isolated [SO₄]²⁻ tetrahedra occupy the interlayer spaces, functioning to balance charge and stabilize the framework (Fig. 22d). Given that the polarization effects of the [IO₃]⁻ units largely cancel each other out within the arrangement, the macroscopic second-order NLO response primarily originates from the superposition of dipole moments generated by the highly distorted [NbO₆]⁷⁻ octahedra. As a result, Nb₂O₃(IO₃)₂(SO₄) exhibits a moderate SHG response, approximately 6 times that of KDP.

6.2 Hg₂(IO₃)₂(SO₄)(H₂O)

Hg₂(IO₃)₂(SO₄)(H₂O) was synthesized via a hydrothermal reaction at 180 °C for 2 days.⁹⁰ Its structure features two distinct types of layers: a [∞][Hg(IO₃)(H₂O)]⁺ layer parallel to the *ab* plane (Fig. 23c), in which Hg²⁺ is coordinated by [IO₃]⁻ anions and water molecules; and a separate [SO₄]²⁻ anionic layer (Fig. 23a) intercalated between the Hg-iodate layers. These [SO₄]²⁻ layers are located in the interlayer region and interconnect the [∞][Hg(IO₃)(H₂O)]⁺ layers via weak interactions, forming a 3D framework (Fig. 23b). The key structural units-polar [IO₃]⁻ groups, distorted [HgO₈]⁶⁻ polyhedra, and [SO₄]²⁻ tetrahedra with induced dipole components-all possess net dipole moments

aligned along the *b*-axis. This coherent alignment leads to a strong SHG response of 6 × KDP, demonstrating that the ordered arrangement and synergistic interaction of multiple polar building blocks are crucial for achieving enhanced NLO performance.

6.3 AgBi(SO₄)(IO₃)₂

AgBi(SO₄)(IO₃)₂ was obtained via a hydrothermal reaction in H₂SO₄ medium at 230 °C for 4 days.⁹¹ Its structure is constructed from Bi-centered layers through two distinct coordination modes. The [Bi(1)O₈]¹³⁻ polyhedra share O atoms with adjacent [IO₃]⁻ groups, generating a [∞][Bi(1)(I₂O₄)O₆]⁷⁻ layer (Fig. 24a). Meanwhile, the [Bi(2)O₈]¹³⁻ polyhedra are corner-shared with [IO₃]⁻ units, forming a [∞][(Bi(2)(IO₃)O₅)]⁸⁻ layer (Fig. 24c). These two types of layers are further interconnected via shared [IO₃]⁻ groups, assembling into [∞][Bi₂I₄O₁₅]⁴⁻ bilayer units (Fig. 24b). These bilayer units are bridged along the *c*-axis by tetrahedral [SO₄]²⁻ anions, resulting in the 3D framework. Two Ag⁺ ions occupy the inter-bilayer spaces. The NLO properties of this compound originate predominantly from the polar [Bi₂I₄O₁₅]⁴⁻ bilayers, within which the dipole moments of the polar [IO₃]⁻ units are cooperatively aligned along *b*-axis. This results in a macroscopically significant SHG effect, with an intensity 3.9 times that of KDP. The structure clearly illustrates how the assembly of layered polar units and 3D connections can achieve effective dipole summation and optimize NLO performance.

6.4 Cd_xMg_{2-x}(IO₃)(PO₄) (x = 2, 1.62)

The isostructural compounds Cd₂(IO₃)(PO₄) and Cd_{1.62}Mg_{0.38}(IO₃)(PO₄), which crystallize in the NCS space group *Fdd*2, were obtained via hydrothermal reactions at 230 °C for 5 days.⁹² Using Cd₂(IO₃)(PO₄) as an example, each Cd atom is coordinated by six O atoms from four [PO₄]³⁻ tetrahedra and two [IO₃]⁻ trigonal pyramids, forming a [CdO₆] octahedron.

Fig. 23 (a) The ${}^2_{\infty}[\text{SO}_4]^{2-}$ layer. (b) View of the structure of $\text{Hg}_2(\text{IO}_3)_2(\text{SO}_4)(\text{H}_2\text{O})$ along the b -axis. (c) The ${}^2_{\infty}[\text{Hg}(\text{IO}_3)(\text{H}_2\text{O})]^+$ layer. Yellow and purple arrows indicate the polarity directions of $[\text{SO}_4]^{2-}$, $[\text{HgO}_8]^{14-}$ and $[\text{IO}_3]^-$. Copyright 2022 Wiley-VCH.

Fig. 24 (a) ${}^2_{\infty}[\text{Bi}(1)(\text{I}_2\text{O}_4)\text{O}_6]^{7-}$ layer. (b) The 3D framework of $\text{AgBi}(\text{SO}_4)(\text{IO}_3)_2$. (c) ${}^2_{\infty}[\text{Bi}(2)(\text{IO}_3)\text{O}_5]^{8-}$ layer. The black arrows indicate the dipole moment of $[\text{IO}_3]^-$. Copyright 2021 Royal Society of Chemistry.

Fig. 25 (a) The group formed by $[\text{IO}_3]^-$ and "Cd4 cores". (b) The group formed by $[\text{PO}_4]^{3-}$ and "Cd4 cores". The $\text{Cd}_4(\text{IO}_3)_{8/4}(\text{PO}_4)_{6/3}$ group (c) and the structure of $\text{Cd}_2(\text{IO}_3)(\text{PO}_4)$ along the diagonal direction (d). The blue lines do not represent the bonds, which could show the structure better. Copyright 2022 Royal Society of Chemistry.

From a topological perspective, the 3D framework can be rationalized as an assembly of tetranuclear Cd4 cores, interconnected through $[\text{IO}_3]^-$ and $[\text{PO}_4]^{3-}$ bridging units. Each $[\text{IO}_3]^-$ group links three adjacent Cd4 cores (Fig. 25a), whereas each $[\text{PO}_4]^{3-}$ group connects four such cores (Fig. 25b). In turn, every Cd4 core is surrounded by eight $[\text{IO}_3]^-$ and six $[\text{PO}_4]^{3-}$ groups, which together generate $\text{Cd}_4(\text{IO}_3)_{8/4}(\text{PO}_4)_{6/3}$ building units via corner- and edge-sharing (Fig. 25c). These units propagate in three dimensions to yield the complete polar framework (Fig. 25d). Notably, these materials exhibit strong SHG responses, measuring approximately

4 and $3.5 \times \text{KDP}$ for $\text{Cd}_2(\text{IO}_3)(\text{PO}_4)$ and $\text{Cd}_{1.62}\text{Mg}_{0.83}(\text{IO}_3)(\text{PO}_4)$, respectively.

6.5 $[\text{M}(\text{OH})_2]_3(\text{IO}_3)(\text{SeO}_4) \cdot \text{H}_2\text{O}$ ($M = \text{Ga}, \text{In}$)

$[\text{M}(\text{OH})_2]_3(\text{IO}_3)(\text{SeO}_4) \cdot \text{H}_2\text{O}$ ($M = \text{Ga}, \text{In}$) were synthesized via hydrothermal reactions at 230°C for 2 days in a highly acidic H_2SeO_4 medium using Bi_2O_3 as a mineralizer. The compounds exhibit isostructural crystal structures. $[\text{MO}_2(\text{OH})_4]^{5-}$ octahedra form trinuclear clusters $[\text{M}_3\text{O}_6(\text{OH})_9]^{12-}$ by sharing $(\text{OH})^-$ ions (Fig. 26a).⁹³ These clusters further interconnect via bridging O atoms, extending into a 2D layer ${}^2_{\infty}[\text{MO}_2(\text{OH})_2]^{3-}$. These layers exhibit a unique pore

Fig. 26 (a) $[\text{Ga}_3\text{O}_6(\text{OH})_9]^{12-}$. (b) $[\text{Ga}(\text{OH})_2]_3(\text{IO}_3)(\text{SeO}_4)$ layer. (c) The structure of $[\text{Ga}(\text{OH})_2]_3(\text{IO}_3)(\text{SeO}_4)\cdot\text{H}_2\text{O}$. The H atoms of the lattice water molecules have been omitted for clarity. Copyright 2023 Royal Society of Chemistry.

system featuring 3-MRs and 6-MRs. The $[\text{IO}_3]^-$ and $[\text{SeO}_4]^{2-}$ anions are uniformly distributed within the 3-MRs of the layer (**Fig. 26b**). The $[\text{MO}_2(\text{OH})_2]^{3-}$ layers stack alternately along the *c*-axis in $-\text{ABAB}-$ sequence, with $[\text{IO}_3]^-$ and $[\text{SeO}_4]^{2-}$ groups positioned on opposite sides of each layer. The interlayer regions are occupied by lattice water molecules (**Fig. 26c**). Structural analysis reveals that the introduction of $[\text{SeO}_4]^{2-}$ tetrahedra significantly regulates the arrangement of $[\text{IO}_3]^-$ units, positioning them on the same side of the layer and orienting their intrinsic dipole moments into a common direction. This ordered arrangement enables effective synergistic superposition of the dipole contributions from each polar unit, resulting in these compounds reaching 2.9 and 3.8 times that of KDP.

7. Conclusions and perspectives

Based on a systematic review of recent synthetic approaches for novel iodates, this article highlights five representative strategies and their key advances in the field. From the existing research, the following general patterns and developing trends can be summarized:

- 1) The polymerization of iodate groups can effectively increase the local density of lone-pair electrons within the unit cell, thereby significantly improving the likelihood of the NCS structure formation. This offers a vital chemical and structural foundation for designing and synthesizing polyiodates with exceptional NLO performance.
- 2) Aliovalent substitution serves as an effective chemical modification strategy. Replacing specific structural units in the parent compound, including single-site, dual-site, multi-site, and vacancy positions, enables performance-oriented controllable synthesis and allows the fine-tuning of multiple key properties, such as NLO coefficients, band gap, and LIDTs.
- 3) Introducing planar π -conjugated groups such as $[\text{BO}_3]^{3-}$, $[\text{NO}_3]^-$, and $[\text{C}_3\text{H}_7\text{N}_6]^{3-}$ into iodate systems not only greatly enriches their structural chemistry diversity but also synergistically enhances the SHG efficiency and birefringence through improved electron delocalization and anisotropic polarizability.

- 4) Incorporating tetrahedral units such as $[\text{PO}_4]^{3-}$, $[\text{SO}_4]^{2-}$, and $[\text{SeO}_4]^{2-}$ into iodate primarily optimizes the optical-gap-related properties. The high bond energy of tetrahedral units and the high electronegativity of the atoms work cooperatively to promote a blue shift in the UV absorption edge and widen the optical band gap.

- 5) The high electronegativity of the F atom contributes markedly to broadening the optical band gap of materials. Meanwhile, fluoroiodate anions such as $[\text{IO}_3\text{F}]^{2-}$, $[\text{IO}_2\text{F}_2]^-$, $[\text{IOF}_4]^-$, and $[\text{IO}_2\text{F}_4]^{3-}$ generally exhibit excellent polarizability anisotropy, which favors the synergistic enhancement of the NLO response.

The analysis presented above highlights several general trends in the field and suggests promising avenues for future research:

- i) Expanding systems with π -conjugated units. To date, only two boriodates have been reported, indicating significant limitations in current synthetic methodologies. Future efforts should expand the range of reaction media, including boric acid melting, solvothermal, and ionic-liquid techniques, to overcome the constraints of conventional synthesis. Given the diverse coordination geometries and marked polarizability anisotropy of B-O units, novel boriodates are anticipated to feature structural innovation and breakthroughs in nonlinear optical performance. Research on organic-inorganic hybrid metal iodates remains in its early stages, with extensive room for exploration. The designability and diversity of organic components offer a critical opportunity for property modulation. By rationally selecting organic functional units with high polarizability anisotropy and large hyperpolarizability, hybrid materials can be directionally constructed that combine strong SHG effects with large birefringence, thereby advancing their potential applications in integrated photonics and frequency conversion.
- ii) Halogen-substituted iodates. Halogenated iodates represent a field with considerable room for exploration. Current research on fluoroiodates remains limited, with only eleven compounds reported to exhibit SHG activity, suggesting ample potential for structural diversification and

performance tuning. The fact that all reported chloriodates are SHG-inactive provides a clear direction: to expand research into this class and activate their NLO responses through structural design. For example, introducing chiral organic moieties effectively directs the crystallization of the material into the NCS space group. Bromiodates remain unreported, which can be attributed to the thermodynamic instability associated with substituting the stronger I–O bonds with weaker I–Br bonds during synthesis. It is conceivable that iodate and linear units ($[ICl_2]^-$, $[IBr_2]^-$, $[I_3]^-$) could be integrated within a single compound, creating a mixed-valence system. Such compositional and structural diversity may offer new avenues for tuning physical properties. This possibility remains largely unexplored and thus warrants systematic studies on how halogen substitution affects structure, polarization, and NLO performance. This research direction is expected to enrich iodate NLO materials.

- iii) Extended range of aliovalent substitutions. Current studies on anionic site substitution focus primarily on the replacement of O^{2-} by F⁻. Future research should focus on substituting with halide ions of higher polarizability, such as Cl⁻ and Br⁻. Such substitutions are expected to enhance the microscopic polarizability and macroscopic NLO response of iodates, while maintaining structural stability, providing promising strategies for developing novel iodate materials with enhanced SHG performance.
- iv) Although hydrothermal methods remain the dominant synthetic route for constructing iodate systems, supplemented by boric acid melting and low-temperature solid-state reactions, the synthetic strategies are still limited. In the future, the systematic introduction of non-conventional approaches such as medium/low-temperature vacuum solid-state synthesis could break through the constraints of existing pathways, challenge traditional understanding of iodate structural formation, and thereby enable the discovery of iodate materials with novel topologies and functional properties, further enriching their structural chemistry.
- v) Enhanced integration of theoretical calculation and experimental synthesis. Strengthening the synergy between theory and experiment is crucial for advancing the field. Current experimental research still relies heavily on trial-and-error approaches, with limited controllability and goal-orientation in synthetic pathways. Therefore, it is necessary to establish a combined research paradigm that integrates dedicated iodate material databases, theoretical prediction, and high-throughput screening. Such databases would systematically catalogue known and hypothetical iodate structures, enabling the efficient evaluation of key properties—such as thermodynamic stability, NLO coefficients, and band gaps—and thereby guiding the targeted design and synthesis of materials. Deepening interdisciplinary collaboration between theoretical and synthetic chemists will facilitate a paradigm shift from “trial-and-error” exploration to “database-assisted,

prediction-guided” research, accelerating the discovery and development of high-performance iodate NLO crystals.

iv) Growth of large single crystals. The growth of large single crystals is a critical step toward the practical application of iodate NLO materials. Current studies are predominantly limited to microcrystalline or small-sized crystals, yet device-level applications demand bulk crystal dimensions. Many key optical properties, including SHG coefficients, refractive indices, and LIDTs, are measured on small crystals, and the accuracy and reliability of such measurements are often constrained by sample dimensions. To obtain practically meaningful performance data, it is necessary to grow high-quality single crystals on the millimeter to centimeter scale and systematically evaluate their optical homogeneity and NLO efficiency. Only after acquiring these key parameters can the practical potential of a material for applications such as laser frequency conversion and electro-optic modulation be accurately assessed, thereby bridging the gap between fundamental research and functional implementation in iodate systems. For the growth of the large single crystals, iodates decompose before melting and are unsuitable for high-temperature melt techniques. As a result, they must be grown exclusively in low-to-medium temperature solution environments, including slow evaporation and low-temperature hydrothermal techniques, which have been widely employed for growing high-quality NLO crystals such as KDP and KTP.^{98,99} In both methods, the use of seed crystals is essential to guide nucleation and promote the growth of large, high quality single crystals. Crystal growth requires sufficient solubility of the compound in water or iodic acid solutions. Therefore, alkali metal iodates such as α -LiIO₃, KIO₃, and NaI₃O₈ are the most suitable for large crystal growth because they combine high solubility with well-established growth protocols. In contrast, transition metal iodates generally exhibit lower solubility, making crystal growth more challenging. Nevertheless, under carefully optimized hydrothermal conditions, compounds with sufficient solubility can still yield crystals of appreciable size. For example, NaVO₂(IO₃)₂(H₂O) has been successfully grown as single crystals via hydrothermal methods,¹⁰⁰ demonstrating that crystal growth of transition metal iodates is achievable, albeit with greater complexity than their alkali metal counterparts.
