

Analytical Methods

Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

23

24 **Abstract:** A supramolecular solvent made up of reverse micelles of
25 nonanoic acid, dispersed in a continuous phase of tetrahydrofuran (THF)
26 and water, were proposed for the simple, rapid and efficient
27 microextraction of copper (Cu) and lead (Pb) in water samples prior to
28 flame atomic absorption spectrometry determination. A new Schiff base
29 was synthesized and used as the chelating agent in this study. Some
30 important extraction parameters such as the pH, Schiff base concentration,
31 the composition and volume of the supramolecular solvent and vortex
32 time were evaluated, obtaining the most favorable results. Under the
33 optimized conditions, the calibration curves were linear in the range of
34 10-800 $\mu\text{g L}^{-1}$ for Cu and 10-500 $\mu\text{g L}^{-1}$ for Pb, respectively. The limits of
35 detection (LOD) were 0.29 $\mu\text{g L}^{-1}$ and 0.45 $\mu\text{g L}^{-1}$, with the enrichment
36 factors of 27 and 22 for Cu and Pb, respectively. Recoveries of Cu and Pb
37 spiked into water samples were in the range of 91.2%-102.1%. The
38 results showed that the proposed method was suitable for the
39 determination of Cu and Pb in water samples.

41 spectrometry, Copper, Lead

42

43 1. Introduction

44 In recently years, pollution of the environment by large amount of
45 toxic elements has been considered as a result of human activities.¹ More

46 and more waste water containing hazardous heavy metals were released
47 into the river, which are harmful to human's body and the environment
48 around. So, determination of the toxic metals such as Cu and Pb in water
49 samples is of significance. Cu is a ubiquitous trace metal in the biosphere,
50 it is an essential and necessary micronutrient for many biological systems
51 at very low levels. However, it becomes toxic at high levels due to its
52 association with cell membranes, preventing the transport across the wall
53 cell.^{2,3} Pb is known to be a toxic metal, which can be accumulates in
54 human body throughout the lifetime.⁴ It can cause adverse effect on
55 metabolic processes of human beings and has been proved to be a
56 carcinogenic agent.⁵ Therefore, determination and monitoring of Cu and
57 Pb at trace levels is of significant importance.

58 Direct determination of metal ions at trace levels is limited due to their
59 low concentrations and matrix interferences. Thus, preconcentration and
60 separation techniques are still very necessary. Various techniques
61 including solid phase extraction (SPE),^{6,7} liquid-liquid extraction (LLE),⁸
62 dispersive liquid-liquid microextraction (DLLME)⁹⁻¹¹ and cloud point
63 extraction (CPE)¹²⁻¹⁴ have been applied for preconcentration and
64 separation of trace amounts of Cu and Pb from environmental samples.

65 In this work, a new extraction technique, supramolecular solvent-based
66 microextraction, was developed as the effective, rapid and inexpensive
67 extraction method for the determination of Cu and Pb in water samples.

68 Supramolecular solvents are introduced to design water-immiscible
69 liquids made up of supramolecular assemblies dispersed in a continuous
70 phase.¹⁵ They are produced from amphiphile solutions by two
71 well-defined self-assembly processes occurring on two scales, molecular
72 and nano. First, amphiphilic molecules self-assemble in the solution
73 above a critical aggregation concentration. Then, the generated
74 nanostructures self-assemble in larger aggregates with a wide size
75 distribution in the nano and micro scale regimes by the action of an
76 external stimulus and separate from the bulk solution by a mechanism
77 that remains elusive.¹⁶⁻¹⁸

78 The supramolecular solvents proposed in this work for the extraction of
79 Cu and Pb was produced from an isotropic solution of reverse micelles of
80 nonanoic acid in THF by addition of water. Schiff base ligands bearing
81 nitrogen and oxygen donor atoms have been shown to exhibit interesting
82 ionophoric properties, in particular towards heavy metal ions.¹⁹ The
83 application of Schiff base in different separation and preconcentration
84 techniques were investigated.²⁰⁻²² This work reports the synthesis of a
85 new Schiff base by using a Schiff base reaction between
86 4-aminoantipyrine and p-dimethylaminobenzaldehyde (DMAB).
87 According to our knowledge, using the Schiff base as chelating agent for
88 supramolecular solvent-based microextraction of Cu and Pb has not been
89 reported before. Below, the main results obtained in optimization studies,

90 analytical features evaluation and analysis of real water samples are
91 presented and discussed.

92

93 **2. Experimental**

94 **2.1 Chemicals**

95 Stock standard solution ($1000 \mu\text{g mL}^{-1}$) of Cu and Pb were obtained
96 from the National Institute of Standards (Beijing, China).
97 Britton-Robinson buffer solution was composed of phosphoric acid, boric
98 acid and acetic acid. 4-aminoantipyrine and DMAB (Aladdin, China)
99 were used for the synthesis of the Schiff base. Octanoic acid, nonanoic
100 acid, decanoic acid and THF were analytical grade and purchased from
101 Sigma (St. Louis, Mo., USA). Purified water was obtained using an Aike
102 water purification system (Chengdu, China) and used as experimental
103 water throughout the research. All the other reagents used were of
104 analytical grade.

105 **2.2 Apparatus**

106 Flame atomic absorption spectrometer (Z-2000, Hitachi, Japan) was
107 used for the determination of metal ions. A vortex oscillator (Shanghai,
108 China) was used to assist the supramolecular solvent-based
109 microextraction procedure. A centrifuge with calibrated centrifugal tubes
110 (Shanghai, China) was used for the phase separation process.

111 **2.3 Supramolecular solvent production**

112 The supramolecular solvent was produced by the following procedure.
113 800 μL of nonanoic acid, 13 mL THF and 20 μL HCl (2 mol L^{-1}) was
114 added in a 50 mL of plastic centrifuge tube, respectively. After this, the
115 mixture was diluted to 50 mL by bidistilled water, and then fiercely
116 stirred by a vortex oscillator for 5 min, time in which the supramolecular
117 solvent spontaneously formed into the bulk solution. Then, the mixture
118 was centrifuged at 3500 rpm for 5 min to speed the supramolecular
119 solvent separation up, which is less dense than water. After this, the
120 solvent was withdrawn using a syringe with a long needle, transferred to
121 a hermetically close storage glass vial to avoid THF losses and stored at
122 $4 \text{ }^\circ\text{C}$. Under these conditions, the supramolecular solvent produced was
123 stable for at least one month.

124 **2.4 Synthesis of Schiff base**

125 The Schiff base was synthesized by the following method: First,
126 solutions of 4-aminoantipyrine (2.03 g, 10 mmol) in ethanol (30 ml) and
127 DMAB (1.49 g, 10 mmol) in ethanol (50 ml) were prepared, respectively.
128 Then, the solution of DMAB was slowly added into the
129 4-aminoantipyrine and the mixture was refluxed at $65 \text{ }^\circ\text{C}$ for 3 h. The
130 yellow precipitate was filtered off and recrystallized three times from
131 methanol. Finally, the product was dried for one day by the method of
132 vacuum drying. The reaction scheme of the synthesis was shown in Fig.
133 1.

134 **2.5 Supramolecular solvent-based microextraction**

135 In this method, Cu and Pb react with Schiff base yielding hydrophobic
136 complexes in aqueous phase, which are then extracted into the
137 supramolecular solvent phase. For the supramolecular solvent-based
138 microextraction under optimum conditions, an aliquot of 10 mL of
139 sample solution or standard solution containing Cu and Pb ($100 \mu\text{g L}^{-1}$),
140 $10 \mu\text{g mL}^{-1}$ of Schiff base, 1 mL of buffer solution (pH 7.0) and 1 mL of
141 supramolecular solvent were placed in a graduated centrifuge tube. Then
142 the mixed solution was fiercely stirred by a vortex oscillator for 5 min.
143 Separation of the two phases was accelerated by centrifugation for 10 min
144 at 3500 rpm. The aqueous phase was then carefully removed by using a
145 syringe with a long needle. And the supramolecular solvent phase was
146 diluted with methanol solution containing $1.0 \text{ mol L}^{-1} \text{ HNO}_3$ to 1 mL and
147 determined by FAAS.

148

149 **3. Results and discussion**

150 **3.1 FT-IR spectroscopy analysis of the synthesized Schiff base**

151 FT-IR spectroscopy analysis has been widely employed for the
152 characterization of organic functional groups bonded organic and
153 inorganic solid phases. The FT-IR spectra of DMAB and the synthesized
154 Schiff base are given in Fig. 2. From the Fig. 2, we can get the following
155 information: First, stretching vibration absorption at 1750 cm^{-1} is the

156 characteristic absorption peaks of C=O in the aldehyde group. But it has
157 disappeared. This result demonstrated that DMAB has reacted completely,
158 which may indirectly illustrate the formation of C=N. Second, the
159 stretching vibration absorption at 1647 cm^{-1} is belong to C=N in
160 synthesized Schiff base. Third, the stretching vibration absorption at 1454
161 cm^{-1} , 1503 cm^{-1} , 1579 cm^{-1} and 1590 cm^{-1} are the characteristic
162 absorption peaks of C-H in the benzene ring. Based on the above analysis,
163 we can infer that the Schiff base has been synthesized successfully.

164 **3.2 Effect of pH**

165 The pH plays a unique role on the metal complex formation and
166 subsequent extraction. For this reason, the effect of pH on the extraction
167 efficiency was investigated in the range of 1-11. Fig. 3 shows the effect of
168 pH on the extraction of the Cu and Pb complexes. It was found that the
169 maximum extraction efficiency was obtained at the pH 7.0. So, a pH of
170 7.0 was selected in subsequent experiments.

171 **3.3 Effect of the Schiff base concentration**

172 In order to investigate the concentration of Schiff base on the
173 extraction efficiency of Cu and Pb, different concentrations of the Schiff
174 base in the range of $1\text{-}20\text{ }\mu\text{g mL}^{-1}$ were used. As shown in Fig. 4, the
175 recovery of Cu and Pb increased by increasing Schiff base concentration
176 up to $10\text{ }\mu\text{g mL}^{-1}$. Hence, $10\text{ }\mu\text{g mL}^{-1}$ of Schiff base was used in
177 subsequent experiments

178 **3.4 Effect of the composition and volume of the supramolecular** 179 **solvent**

180 Three types of organic acid including octanoic acid, nonanoic acid and
181 decanoic acid were selected to the supramolecular solvent production. Its
182 formation occurs through two sequential self-assembly processes. First,
183 the organic acid molecules aggregate as reverse micelles in THF. Then,
184 under the addition of water, they rearrange in larger reverse micelles that
185 separate from the bulk solution, as an immiscible liquid, through a
186 mechanism that remains elusive. The immiscible liquid is made up of
187 reverse micelles, THF and water. And the effect of three types of
188 supramolecular solvent on the recovery of Cu and Pb were investigated.
189 As shown in Fig. 5, compared with octanoic acid and decanoic acid,
190 supramolecular solvent formed by nonanoic acid and THF could obtain
191 the best extraction efficiency. Therefore, it was selected as the best
192 extraction solvent for this study. And the effect of the volume of this
193 supramolecular solvent on the presented method was also investigated.
194 As it is shown in Fig. 6, 1 mL of the supramolecular solvent was chosen
195 as the optimum volume for this study.

196 **3.5 Effect of the vortex time**

197 Vortex process plays an important role in this study. Firstly, it was used
198 to accelerate the supramolecular solvent spontaneously formed into the
199 bulk solution. According to our experiments, 5 min of vortex time was

200 appropriately for the formation of the supramolecular solvent. Secondly, a
201 vortex process was applied to mix the solution thoroughly and obtain
202 good extraction efficiency. For this reason, the vortex time was
203 investigated in the range of 0-10 min. As can be seen from Fig. 7, the
204 recovery of Cu and Pb was increased by increasing the vortex time up to
205 5 min. Therefore, 5 min of vortex time was chosen as the optimal time in
206 this study.

207 **3.6 Analytical features**

208 Under the optimized conditions, the analytical performance of the
209 proposed method was evaluated. A calibration curve was constructed by
210 preconcentrating of 10 ml of sample solutions with supramolecular
211 solvent. The calibration graph was linear in the range of 10-800 $\mu\text{g L}^{-1}$
212 and 10-500 $\mu\text{g L}^{-1}$ for Cu and Pb, respectively. The limit of detection
213 (LOD), defined as $C_L=3S_B/m$ (where C_L , S_B , and m are the limit of
214 detection, standard deviation of the blank, and slope of the calibration
215 graph, respectively), are 0.29 $\mu\text{g L}^{-1}$ and 0.45 $\mu\text{g L}^{-1}$ for Cu and Pb. Other
216 analytical features of the proposed method such as calibration equation,
217 correlation coefficient and the relative standard deviation (RSD) were
218 also investigated. The results were shown in Table 1.

219 **3.7 Interference study**

220 The effect of other ions in the extraction of Cu and Pb was studied
221 under optimized conditions. To perform this study, 10 mL of solution

222 containing $50 \mu\text{g L}^{-1}$ of Cu and Pb and different concentrations of other
223 interfering ions were prepared and subjected to the extraction procedure.
224 The tolerance limit was defined as the foreign ion concentration causing a
225 change in the absorbance of less than $\pm 5\%$. The results are shown in
226 Table 2. And these results showed that the presence of large amounts of
227 foreign ions commonly presents in water samples have no significant
228 effect on the supramolecular solvent-based microextraction of Cu and Pb
229 in water samples.²³⁻²⁴

230 **3.8 Analysis of real samples**

231 Three types of water samples including tap water, river water and
232 industrial wastewater were analyzed to assess their content in Cu and Pb.
233 The samples were filtered to remove the suspended solids and then 10 ml
234 of each of the samples were preconcentrated by proposed method in this
235 study. The results (Table 3) demonstrated that the proposed method can
236 be successfully applied for the preconcentration and determination of Cu
237 and Pb in water samples.

238

239 **4. Conclusions**

240 In this study, a supramolecular solvent made up of reverse micelles of
241 nonanoic acid, dispersed in a continuous phase of THF and water, was
242 proposed as a simple, rapid and efficient microextraction of Cu and Pb in
243 water samples prior to flame atomic absorption spectrometry

244 determination. The Schiff base used in this study is easy to be synthesized,
245 and it is proved to be an efficient chelating reagent for Cu and Pb. An
246 obvious higher extraction efficiency of Cu and Pb was obtained by a
247 vortex-assisted process. The presented method can be successfully
248 employed for the determination of Cu and Pb in water samples.
