Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

45
46 19 **Abstract**
47

48 20 A simple and efficient solid phase membrane tip extraction (SPMTE) was developed using
49
50 21 mesoporous silica MCM-41 adsorbent for the determination of three azole antifungal drugs in
51
52 22 human plasma prior to high performance liquid chromatography (HPLC). Three azole drugs,
53
54 23 namely voriconazole (VRZ), ketoconazole (KTZ) and itraconazole (ITZ) were used as target
55
56
57
58
59
60

1
2
3 24 analytes. The plasma was deproteinized prior to the extraction using methanol-dichloromethane
4
5 25 (75:25, v/v). Optimized extractions were obtained using the following conditions: conditioning
6
7
8 26 solvent, acetone; extraction time, 15 min; desorption time, 15 min; salt addition, 10 % (w/v); pH
9
10 27 of sample solution, 8; sample volume, 15 mL and desorption solvent, methanol. A portion of the
11
12 28 clean extract (20 μL) was injected into the HPLC-UV system for analysis. Under the optimized
13
14 29 conditions, the method demonstrated good linearity with correlation of determination, $r^2 \geq 0.9958$
15
16 30 in the concentration range of 60 - 8000 $\mu\text{g L}^{-1}$ and good limits of detection in the range of 20 - 40
17
18 31 $\mu\text{g L}^{-1}$. The method showed satisfactory precisions with RSDs <16 % (n = 3) and high relative
19
20 32 recoveries in the range of 82.5 - 111.0 %. The MCM-41-SPMTE method proved to be simple,
21
22 33 efficient, and requires minimal amounts of organic solvent that supported the green chemistry
23
24 34 concept.

39

40 39 1. Introduction

41 40
42 41 The compression of body's immune system during therapeutic treatments such as organ
43 42 transplantation, use of immunosuppressive agents in cancer treatment, or diseases such as
44 43 acquired immunodeficiency syndrome (AIDS) urge the occurrence of mycosis in humans [1].
45 44 The other cause of mycosis is the improper use of broad spectrum antibiotics that reduce the
46 45 bacterial population which commonly competing with fungi. Therefore, the development of
47 46 antifungal drugs are crucial in order to find agents which arrive at the infection focus [2].
48 47 Voriconazole (VRZ) and itraconazole (ITZ) are drugs belonging to a group of antifungal
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 48 compounds called triazole while ketoconazole (KTZ) belongs to the imidazole group. These are
4
5 49 systemic azole drugs (medicines taken orally or by injection). The chemical structure, protein
6
7
8 50 binding %, partition coefficient ($\text{Log } P$) and dissociation constant of a solution ($\text{p}K_a$) [3] for each
9
10 51 azole antifungal drug are described in Table 1. The quantification of plasma concentrations of
11
12 52 VRZ, KTZ and ITZ is very important to determine toxicological profile and drug tolerance in
13
14
15 53 humans. Previous clinical studies proposed that plasma VRZ concentrations of $>6 \mu\text{g mL}^{-1}$ were
16
17 54 associated with occasional liver function abnormalities [4]. KTZ is an azole drug that is
18
19
20 55 commonly used for systemic and local infections [5]. Clinical studies suggested that azole may
21
22 56 participate in interaction with many drugs in the event of substantial amounts of the residues in
23
24 57 the human body [6]. Therefore, a fast, simple, accurate and inexpensive analytical method for the
25
26
27 58 monitoring of antifungal azole drugs in human plasma is crucial to provide the association
28
29 59 between drug concentration and response.
30
31

32 60
33
34 61 Several analytical instruments have been used for the analysis of azole antifungal drugs
35
36 62 including liquid chromatography [7-9], gas chromatography [10] and capillary electrophoresis
37
38 63 [11, 12]. The most common methods for the determination of azole antifungal drugs in water and
39
40 64 biological samples were high performance liquid chromatography (HPLC) coupled with mass
41
42 65 spectrometry [13, 14] and HPLC with ultraviolet detector [15, 16]. However, identification and
43
44 66 quantification of targeted drugs in complex matrices may be difficult due to high levels of
45
46 67 interferences and lower detection ability of instrument. Thus, the development of appropriate
47
48 68 sample preparation is required to eliminate major interferences and to concentrate the target
49
50
51 69 analytes in the complex matrices prior to the final instrumental analysis [17].

1
2
3 71 Numerous sample preparation methods have been developed for the analysis of azole antifungal
4
5 72 drugs in biological, environmental and formulations samples including liquid-liquid extraction
6
7
8 73 (LLE) [18] and solid phase extraction (SPE) [19-22]. LLE has drawbacks of time consuming,
9
10 74 labour intensive and requires large volumes of organic solvents. SPE has significant
11
12 75 improvement over LLE, but it is relatively expensive. The development of microextraction
13
14 76 methods for azole drugs such as ultrasound-enhanced surfactant-assisted dispersive liquid-liquid
15
16 77 microextraction (UESA-DLLME) [5], liquid phase microextraction (LPME) [16] and
17
18 78 solidification of floating organic drop dispersive liquid-liquid microextraction (SFODME) [23]
19
20 79 have greatly reduced the organic solvent consumption and produced less waste. Recently-
21
22 80 introduced solid phase membrane tip extraction (SPMTE) is an interesting microextraction
23
24 81 method due to its advantages in terms of simplicity, low solvent usage, easy to use and low
25
26 82 analysis cost. SPMTE has been successfully applied to the determination of atrazine herbicides
27
28 83 [24] and organochlorine and pyrethroid pesticides [25] in water samples.
29
30
31
32
33
34
35

36 85 Since discovered by Mobil researchers in 1992 [26], mesoporous silica, MCM-41 has drawn
37
38 86 great interests due to its special characteristics of large surface area ($>1000 \text{ m}^2 \text{ g}^{-1}$), uniform pore
39
40 87 structure (20 - 50 nm) and huge pore volume ($>0.7 \text{ cm}^3 \text{ g}^{-1}$) [27]. MCM-41 offered promising
41
42 88 applications in catalysis [28], sensor design [29], drug delivery [30] and separation techniques
43
44 89 [31]. Due to its special characteristics and strong adsorption ability, MCM-41 and organo-
45
46 90 functionalized MCM-41 have been successfully used as the solid phase microextraction (SPME)
47
48 91 coating for the analysis of polycyclic aromatic hydrocarbons (PAHs) [32-34]. More recently,
49
50 92 MCM-41 has been used as adsorbent for the determination of PAHs in gaseous samples [35].
51
52

54
55
56
57
58
59
60

1
2
3 93 Nevertheless, the development of microextraction methods to extract azole antifungal drugs in
4
5 94 biological sample is still limited.
6
7
8 95

9
10 96 In the present study, MCM-41 was employed as adsorbent in SPMTE for the extraction of
11
12 97 selected azole antifungal drugs in human plasma followed by HPLC with ultraviolet (HPLC-UV)
13
14 98 detection. This method provided a simple and efficient microextraction means for the
15
16 99 determination of selected azole drugs in human plasma.

25
26
27 105 Tetraethyl orthosilicate (TEOS) and cetyltrimethylammonium bromide (CTABr) were purchased
28
29 106 from Sigma-Aldrich (St. Louis, MO, USA). Ammonia solution (NH₄OH) (28 %) and
30
31 107 hydrochloric acid (36 %) were obtained from QRēC Asia (Selangor, Malaysia). Potassium
32
33 108 dihydrogen phosphate, sodium hydroxide, dichloromethane, acetone, isopropanol and acetic acid
34
35 109 were purchased from Merck (Darmstadt, Germany). All chemicals were of analytical-reagent
36
37 110 grade. HPLC grade methanol and acetonitrile were obtained from J.T. Baker (Pennsylvania,
38
39 111 USA). Deionized water of 18.2 MΩ was purified by Nano ultrapure water system (Barnstead,
40
41 112 USA). Analytical grade sodium chloride (NaCl) was purchased from Bendosen (Selangor,
42
43 113 Malaysia). Voriconazole (>95 %) was obtained from Clearsynth (Mumbai, India) while
44
45 114 ketoconazole (98 %) and itraconazole (98 %) were purchased from Sigma-Aldrich (St. Louis,
46
47 115 MO, USA). Stock standard solutions (1000 μg mL⁻¹) of the azole drugs were prepared in

10 119

12 120 2.2 Sample Collection and Pretreatment

13 121

14
15
16
17 122 Human plasma samples were obtained from Penang General Hospital (Penang, Malaysia) and
18
19
20 123 stored at $-4\ ^{\circ}\text{C}$ prior to use. The frozen samples were thawed in water at room temperature
21
22 124 (25°C) before use. The thawed samples were vortexed to ensure complete mixing of the contents.
23
24
25 125 The plasma sample (3 mL) was transferred into a 15-mL centrifuge tube and spiked with the
26
27 126 mixed standard solutions at different concentrations. After adding $500\ \mu\text{L}$ of 100 mM potassium
28
29 127 dihydrogen phosphate buffer (pH 8), the solution was vortexed to ensure uniform mixing. The
30
31
32 128 solution was added with 3 mL of methanol-dichloromethane (75:25, v/v) and centrifuged for 10
33
34 129 min at 6000 rpm. The resulting supernatant (approximately 7 mL) was added with 10 % (w/v) of
35
36 130 NaCl and diluted with distilled water to 15 mL.
37

38 131

39 132 2.3 Preparation of MCM-41-SPMTE tip

40 133

41
42
43
44
45
46 134 The SPMTE procedure was adopted from a previously reported work [24] with slight
47
48 135 modification on the type of adsorbent. In brief, the SPMTE device consisted of MCM-41
49
50 136 enclosed in PP membrane attached to $1000.0\ \mu\text{L}$ pipette tip. MCM-41 was synthesized using the
51
52
53 137 molar gel composition and synthesis conditions as reported previously [36]. A PP sheet
54
55
56 138 membrane was cut into an equilateral triangle with each side of approximately 15 mm. The edge
57
58
59
60

1
2
3 139 of the membrane was folded to form a scalene triangle shape with sides of 15, 13 and 7.5 mm.
4
5
6 140 The edge of the longest flap was then heat-sealed using a portable sealer. A portion (3 mg) of
7
8 141 MCM-41 was added into the cone-shaped membrane and the open edge was then heal-sealed to
9
10 142 secure the adsorbents. Each tip was cleaned in acetone for 10 min and then stored in the same
11
12 143 solvent until use. The 1000.0 μL pipette tip end was cut-off approximately 7.0 mm length and
13
14 144 the cone-shaped membrane was inserted into the end of the modified tip. The schematic of
15
16
17 145 MCM-41-SPMTE is shown in Fig. 1.
18
19
20 146
21
22 147 2.4 MCM-41-SPMTE Procedure
23
24 148
25
26
27 149 Solid phase membrane tip was placed in 15 mL of diluted human plasma that was stirred at 1000
28
29 150 rpm. A dynamic extraction procedure was carried out at 5 min interval of the extraction. A 600
30
31 151 μL of aqueous sample was withdrawn into the tip at constant low speed using a digital
32
33 152 micropipette (Eppendorf, Germany). After a dwelling time of approximately 3 s, the withdrawn
34
35 153 aqueous sample was released from the tip back into the sample vial at constant low speed. This
36
37 154 procedure was repeated for 5 times and the micropipette was detached from the tip. The dynamic
38
39 155 extraction procedure was repeated at every 5 min interval until the end of extraction. After
40
41 156 extraction, the cone-shaped membrane was removed, rinsed in ultrapure water, dried with lint-
42
43 157 free tissue and placed in a 500 μL safe-lock tube. The analytes were desorbed by ultrasonication
44
45 158 for 15 min in methanol (100 μL) and 20 μL of the solution was injected into the HPLC system.

52
53 160 2.5 Chromatographic Conditions
54
55
56 161
57
58
59
60

1
2
3 162 The HPLC system (Waters LC) consisted of a pump, a Rheodyne 3699 injector, sample injection
4
5 163 valve with a 20- μ L internal loop for sample introduction, and a UV detector (Shimadzu, Japan)
6
7
8 164 was used for chromatographic analysis. The separation was performed on a 5.0 μ m Zorbax SB-
9
10 165 C₁₈ column (4.6 μ m I.D. \times 100 mm) (Agilent Technology, USA) and the mobile phase was a
11
12 166 mixture of 10 mM phosphate buffer (adjusted to pH 6.5 with 1 M potassium hydroxide)-
13
14
15 167 acetonitrile (35:65, v/v) at a flow rate of 1.0 mL min⁻¹. Detection was monitored at 254 nm.
16
17
18 168

19 169 **3. Results and Discussion**

20 170 21 22 171 3.1 Optimization of MCM-41-SPMTE 23 24 25 26 27 172

28
29 173 In order to optimize the extraction, seven parameters namely conditioning solvent, extraction
30
31 174 time, sample pH, salt addition, sample volume, desorption solvent and desorption time were
32
33 175 investigated.
34
35
36 176

37 38 177 3.1.1 Conditioning Solvents and Extraction Time 39 40 41 178

42
43 179 The conditioning solvent was used to activate the hydrophobic nature of PP membrane
44
45 180 containing MCM-41 by immersing the membrane in the organic solvents for 2 min prior to the
46
47 181 microextraction. In the present study, several organic solvents, namely methanol, acetonitrile,
48
49 182 isopropanol, acetone and dichloromethane were tested as conditioning solvent in MCM-41-
50
51 183 SPMTE. It was found that acetone gave the highest peak areas response for VRZ and KTZ, while,
52
53 184 ITZ showed the highest peak area when dichloromethane was used as conditioning solvent (Fig.
54
55 185 2). As compared to dichloromethane, acetone showed increased peak areas of about 173 % and
56
57
58
59
60

1
2
3 186 24 %, for VRZ and KTZ, respectively, while for ITZ, the peak area was slightly decreased by
4
5
6 187 only about 10 %. Therefore, acetone was used as conditioning solvent in subsequent analyses to
7
8 188 activate the PP membrane containing MCM-41 adsorbent and to ensure the reproducible
9
10 189 retention of analytes during the extraction process.
11
12
13 190

14
15 191 As mass transfer is a time-dependent process, the effect of extraction time was investigated in the
16
17 192 range of 5 to 20 min. In SPMTE, the extraction-time profile of target analytes is important to
18
19 193 configure the time after which equilibrium is achieved in the system. It was found that there was
20
21 194 a rapid increase in extraction efficiency of all analytes when the extraction time was prolonged
22
23 195 from 5 to 15 min and the peak areas remained nearly constant or slightly decreased when the
24
25 196 extraction time was further increased (20 min) (Fig. 3). This phenomenon might be due to the
26
27 197 back-extraction of analytes from adsorbent into sample solution [24]. Thus, 15 min was selected
28
29 198 as the optimum extraction time and used in further experiments.
30
31
32
33
34 199

35 36 200 3.1.2 Sample pH, Salt Addition and Sample Volume 37 38 39 201

40
41 202 Sample pH is one of the most important parameters in the extraction process. The studied azole
42
43 203 antifungal drugs possess weak base moiety and can be present in water in both ionized and
44
45 204 neutral forms. The extraction of analytes in their neutral form is expected to be easier than when
46
47 205 they exist in ionized form. Since VRZ, KTZ and ITZ are weak base azole drugs with a pK_a
48
49 206 values from 2.27-12.71 (Table 1), the pH of the solution was varied from pH 7.0 to 8.5 in order
50
51 207 to assemble the neutral form of analytes to assist the extraction. The best extraction efficiency
52
53
54
55
56
57
58
59
60

1
2
3 208 was obtained at pH 8 which gave the highest peak areas that corresponded to the pK_a values of
4
5 209 all analytes (VRZ, KTZ and ITZ). Therefore, pH 8.0 was chosen and used in further analyses.
6
7

8 210
9
10 211 The addition of NaCl may change the ionic strength and the solubility of analytes in the sample
11
12 212 solution. The effect of salt addition on the extraction efficiency was evaluated by the addition of
13
14 213 NaCl from 0 to 25 % (w/v) into the sample solution. The results showed an increase of peak area
15
16 214 response for two of theazole drugs (VRZ and ITZ) from 0 to 10 % (w/v) of NaCl addition, but
17
18 215 KTZ showed the highest peak area at 5 % (w/v) of NaCl addition (Fig. 4). At 10 % NaCl
19
20 216 addition, peak area of KTZ slightly decreased by about 2.5%, while peak areas of VRZ and ITZ
21
22 217 showed an increase of about 33 % and 26 %, respectively. However, thereafter, the peak areas of
23
24 218 all analytes dropped when 15 % of NaCl was added into the sample solution due to the high
25
26 219 viscosity of sample solution which decreased the diffusion rate of the analytes [37]. Therefore, to
27
28 220 compromise the efficiency for all analytes, 10 % (w/v) of NaCl was used for all subsequent
29
30 221 experiments.
31
32
33
34
35
36
37
38

39 223 Sample volume was used to determine the adsorption capacity of MCM-41 after the equilibrium
40
41 224 was attained. The results showed that the optimum sample volume was at 15 mL which gave
42
43 225 highest peak area responses for VRZ and ITZ. However, in case of KTZ, highest peak area was
44
45 226 obtained when 10 mL of sample solution was applied in the extraction (Fig. 5). Based on the
46
47 227 results obtained at 15 mL sample volume, peak areas of VRZ and ITZ increased by about 19 %
48
49 228 and 2 %, respectively, while peak area of KTZ decreased by about 4 %. The drop in peak area
50
51 229 response for all analytes was observed when larger sample volume (20 mL) was applied in the
52
53 230 extraction probably due to the saturation of MCM-41 (~ 3 mg) capacity for a larger sample
54
55
56
57
58
59
60

1
2
3 231 volume [24]. To compromise the extraction performance for all analytes, sample volume of 15
4
5
6 232 mL was used in subsequent experiments.

7 233 3.1.3 Desorption Solvent, Desorption Time and Volume of Desorption Solvent

8
9
10 234
11
12 235 In this study, the choice of the desorption solvent relies on its compatibility with the liquid
13
14 236 chromatographic system. The organic solvents with different polarity indices, namely methanol
15
16 237 (5.1), acetonitrile (5.8), isopropanol (3.9) and tetrahydrofuran (4.0) were examined [38]. Due to
17
18 238 theazole's relatively polar properties, a polar solvent should give better results than a less polar
19
20 239 solvent. It was found that methanol gave the highest peak areas for KTZ and ITZ, while
21
22 240 acetonitrile and methanol showed similar peak areas for VRZ (Fig.6). Thus, in order to obtain the
23
24 241 best extraction performance for all studied analytes, methanol was used as desorption solvent for
25
26 242 all subsequent analyses.
27
28
29
30
31
32 243

33
34 244 The desorption time is the time that is required to desorb all the analytes from the MCM-41 in
35
36 245 the extraction tip. In order to evaluate the effect of desorption time, the PP tip was ultrasonicated
37
38 246 in different durations in the range of 5 to 20 min. It was found that the maximum desorption was
39
40 247 achieved within 15 min. Beyond this point (20 min), the desorption efficiency of all analytes
41
42 248 decreased probably due to the analytes being re-adsorbed by the adsorbent (Fig. 7) [39]. Thus, 15
43
44 249 min desorption time was used for subsequent experiments. Desorption volume of 100 μ L was
45
46 250 used as that is the lowest volume to fully submerge the PP tip.
47
48
49
50
51
52

53 252 3.2 Method Validation

54
55 253
56
57
58
59
60

1
2
3 254 Under the optimum conditions, the proposed method was validated in terms of linearity, limit of
4
5 255 detection (LOD), limit of quantification (LOQ), precision and recovery. The MCM-41-SPMTE
6
7
8 256 validation data obtained are shown in Table 2. Linear calibration curve was obtained by plotting
9
10 257 different concentrations of spiked plasma sample ranging from 60 to 8000 $\mu\text{g L}^{-1}$. Good linearity
11
12 258 was observed for SPMTE method with correlation of determination, $r^2 \geq 0.9958$ for all target
13
14 259 analytes. LODs were calculated as three times the signal-to-noise ratio ($S/N * 3$) and LOQs
15
16 260 measured as ten times the signal-to-noise ratio ($S/N * 10$). The LODs and LOQs for azole drugs
17
18 261 were in the range of 20 - 40 $\mu\text{g L}^{-1}$ and 60 - 100 $\mu\text{g L}^{-1}$, respectively.
19
20
21
22 262

23
24 263 Intra- and inter-day precisions were determined at low, medium and high concentrations (100,
25
26 264 2000, 8000 $\mu\text{g L}^{-1}$) with triplicate analyses on the same day and over three different days using
27
28 265 plasma sample, respectively. The results showed acceptable relative standard deviations (RSDs)
29
30 266 ranging from 2.6 to 9.0 % ($n = 3$) and 8.0 to 15.4 % ($n = 3$) for intra- and inter-day precision,
31
32 267 respectively (Table 3), signifying the good precision of the developed method.
33
34
35
36 268

37 269 3.3 Analysis of Human Plasma Samples

38
39 270
40
41
42
43 271 In initial experiments, no azole drugs were detected in the human plasma samples. Therefore, in
44
45 272 order to assess the usefulness of the method, different concentrations of analytes were spiked in
46
47 273 the sample. Relative recoveries of the method were calculated based on the percentage ratio
48
49 274 between the concentration found in the sample and concentration spiked in the same sample of
50
51 275 each analyte. The proposed MCM-41-SPMTE method that was conducted under the optimum
52
53 276 conditions provided high relative recoveries in the range of 82.5 - 111.0 % for azole drugs at
54
55
56
57
58
59
60

1
2
3 277 different concentrations (low, medium and high) (Table 3). Chromatograms of drug-free plasma
4
5 278 and spiked plasma (Fig. 8) indicated a clean sample pretreatment provided by the proposed
6
7
8 279 method thus suitable for quantification of the concentrations of selected drugs in human plasma
9
10 280 samples.

11 281

12 282 3.4 Comparison with Other Reported Methods

13 283

14
15 284 The analytical characteristics of the proposed MCM-41-SPMTE method were compared with
16
17 285 other reported methods (Table 4). LPME [16] and SFODME [23] methods resulted in excellent
18
19 286 sensitivity for azole drugs, however, it requires relatively longer extraction time to reach
20
21 287 equilibrium for each analysis (≥ 35 min). The LOD, precision and recovery of MCM-41 were
22
23 288 comparable to other reported liquid chromatography method [18, 21, 22]. The use of 3 mg of
24
25 289 adsorbent and organic solvent (100 μ L) have added incentives in MCM-41-SPMTE as an
26
27 290 alternative microextraction method for azole drugs. Furthermore, MCM-41-SPMTE has the
28
29 291 advantage of simplified analytical extraction process without sacrificing high recoveries by using
30
31 292 simple devices and ultrasonication system.

32 293

33 294 4. Conclusions

34 295

35 296 The present study has successfully developed a simple, and efficient microextraction method of
36
37 297 azole antifungal drugs in human plasma. Parameters that affected the extraction efficiency
38
39 298 including conditioning solvent, extraction time, sample pH, salt addition, sample volume,
40
41 299 desorption solvent and desorption time were examined thoroughly throughout the study. MCM-

42

43

44

45

46

47

1
2
3 300 41-SPMTE method showed acceptable sensitivity with satisfactory precision and recoveries of
4
5 301 azole drugs in human plasma. The use of only small amounts of adsorbent and minute amounts
6
7 302 solvent have added great consideration for MCM-41-SPMTE to be an alternative “green”
8
9 303 microextraction methods for azole drugs determination in human plasma.

HPLC-MS/MS- High performance liquid chromatography- tandem mass spectrometry

SPE- Solid phase extraction

LPME- Liquid phase microextraction

LLE- Liquid-liquid extraction

SFODME- Solidification of floating organic drop microextraction

MCM-41-SPMTE- Mesoporous silica, MCM-41 solid phase membrane tip extraction
