24

25  
26  
27 A novel automatic low-cost sequential injection lab-at-valve (SIA-LAV) system  
28  
29 has been developed for inorganic arsenic determination coupled with hydride  
30  
31 generation atomic absorption spectrometry (HG-AAS). The proposed manifold  
32  
33 includes an integrated gas liquid separator / reaction chamber (GLS-RC) which was  
34  
35 attached to one port of a conventional six-port multiposition selection valve. The  
36  
37 arsine vapour is generated by reductant  $\text{NaBH}_4$  into the GLS-RC, minimizing its  
38  
39 dispersion and possible losses. All critical parameters affecting the efficiency of the  
40  
41 system were studied and optimised. For 3.0 mL sample consumption the detection  
42  
43 limit was  $0.05 \mu\text{g L}^{-1}$  and the precision expressed as RSD was 3.2%. The proposed  
44  
45 method was evaluated in comparison with a reference flow injection HG method and  
46  
47 applied for arsenic determination in environmental water samples. The recovery was  
48  
49 estimated by spiking the samples and ranged from 95.5% up to 102.5% for both  
50  
51 As(III) and As(V).

## Introduction

The chemical form of arsenic plays a crucial role in the biochemical, medicinal, and toxicological properties of the element. Inorganic arsenic is by far more toxic than the organic one, with arsenite (As(III)) and arsenate (As(V)) being of particular concern because of their high toxicity and water solubility. Human exposure to elevated levels of inorganic arsenic occurs mainly through the consumption of groundwater, food prepared with this water or food crops irrigated with high arsenic water sources [1]. Inorganic arsenic compounds are classified by the International Agency for Research on cancer [2] in Group 1 (carcinogenic to humans) on the basis of sufficient evidence for carcinogenicity in humans and limited evidence for carcinogenicity in animals. According to EPA and WHO, the recommended value for total arsenic in drinking water has decreased from 50 to 10  $\mu\text{g L}^{-1}$  [3, 4].

The increasing concern for human exposure to arsenic species has led to the development of rapid analytical methods for their determination in trace levels. There are various examples of surveys concerning arsenic determination using hydride generation systems coupled with an element selective detector [5]. Hydride generation methods in batch or on-line mode involve the reaction of arsenic compounds, usually with sodium tetrahydroborate ( $\text{NaBH}_4$ ) in acidic medium to produce arsine vapor ( $\text{AsH}_3$ ) [6].

Undoubtedly, batch methods may lead to operating errors particularly in cases when a large number of samples have to be analyzed or a considerable number of reagents and repetitive steps are involved [7]. Automatic on-line flow techniques have proved to be rapid, simple, highly sensitive, precise and accurate for such type of analysis eliminating many disadvantages of batch-HG systems, like high sample and

1  
2  
3 reagents consumption, laborious processes, great risk of contamination and analyte  
4 loss. In literature, many automated on-line hydride generation systems such as  
5  
6 continuous flow (CF) [8, 9], flow injection (FI) [7, 10, 11], sequential injection (SI)  
7  
8 [12, 13], lab-on-valve (LOV) [14, 15], multi-pumping (MPFS) [16] and multisyringe  
9  
10 flow systems (MSFIA) [17, 18] have been developed in order to eliminate the above-  
11  
12 mentioned drawbacks.  
13  
14  
15  
16

17  
18 Following the new trends, according to the guidelines of Green Analytical  
19  
20 Chemistry like simplification, miniaturization, automation of sample handling, shorter  
21  
22 time of analysis, minimization of sample and reagents consumption as well as lower  
23  
24 waste generation, various on-line systems into different concepts have been presented.  
25  
26 The result is the development of analytical methods with demands that are put  
27  
28 together in “SPARS” and “ZEC”, which mean methods with satisfying “sensitivity  
29  
30 and selectivity”, “precision”, “accuracy”, “rapidity”, “simplicity” (SPARS), and quasi  
31  
32 “zero emission” (ZEC) [19].

37

38 Sequential injection analysis (SIA) presented by Ruzicka et al. in 1990 offers  
39  
40 several advantages in the automation and miniaturization of analytical methods [20].  
41  
42 Towards the direction of compactness, simplicity and low reagent consumption, a new  
43  
44 platform, in which an integrated micro-conduit is placed on the top of the selection  
45  
46 valve of a SIA system to incorporate and handle all the necessary unit operations  
47  
48 required for a given assay acting as a small laboratory on the selection valve, namely  
49  
50 lab-on-valve (LOV) has been proposed by Ruzicka in 2000 [21]. Coupling of SIA  
51  
52 with the LOV platform has proven to be an excellent tool for downscaling fluidic  
53  
54 manipulations of sample pretreatments for wet chemical or heterogeneous reactions  
55  
56  
57  
58

Recently, Grudpan [23] introduced a “Lab-at-Valve” concept as an alternative simpler and low-cost micro total analysis system ( $\mu$ TAS) device than that of “LOV”. Instead of replacing the stator plate of a multiposition selection valve by precisely fabricated monolithic structure as that of the “LOV”, sample processing unit is attached or plugged onto a port of a conventional commercial multiposition selection valve. Such an integrated LAV device compiling analytical processes that take place in it, should be compact and economical compared to a normal SIA system. Various advantages similar to those of the LOV like compactness, robustness, low reagent consumption, should be gained with the use of LAV [24].

In the present work, a novel, simple and cost effective sequential injection lab-at-valve (SIA-LAV) system coupled with hydride generation atomic absorption spectrometry (HG-AAS) has been successfully developed for arsenic determination. The proposed system incorporates a newly designed and constructed gas liquid separator acting also as a reaction chamber (GLS-RC), which was attached at one port of the selection valve resulting in a more accessible and economical platform than the LOV systems. All critical chemical and flow parameters, affecting the performance of the proposed method were studied and optimized. The accuracy of the method was evaluated by comparing the analytical results with those obtained using the conventional on-line FI-HG-AAS method. The developed system was successfully applied in the analysis of environmental water samples for inorganic arsenic determination.

A Perkin-Elmer model 5100 PC atomic absorption spectrometer (Perkin-Elmer, Norwalk, CT, USA, <http://las.perkinelmer.com>) equipped with a deuterium background corrector was used as detector. A Perkin-Elmer arsenic hollow cathode lamp (HCL) was used as light source operated at 18 mA. The wavelength was set at 193.7 nm resonance line and the monochromator spectral bandpass (slit) at 0.7 nm. For hydride atomization a Perkin-Elmer FIAS 400 electrothermal quartz flow-through cell atomizer operated at 900 °C was used. The atomic absorption flow-through cell, AAC (16 cm length, 7.0 mm i.d., 14.5 mm e.d.) was sealed with removable quartz windows at either ends and consisted of one inlet, for the mixture of hydride and purge gas and two outlets.

The proposed manifold, which is presented schematically in Fig. 1, comprised of a FIALab-3000 sequential injection system with a 6-position selection valve (SV), a syringe pump (SP, Cavro, Sunnyvale, CA) of 5000 µL capacity with a valve (V1) on the top of it, a holding coil (HC, 120 cm length, 0.21 mm i.d., 4 mL capacity) as well as a 2-position valve (V2) for the manipulation of the purge gas.

The FIALab-3000 SI system and the Perkin-Elmer 5100 AAS were controlled by a personal computer via the FIALab v.5.9.245 and AA Lab Benchtop v.7.2. application softwares, respectively. A “T” type connector (C, VICI AG, Valco International) made of PEEK with a 0.5 mm i.d. bore size was used as shown in Fig. 1.

The design of the integrated gas liquid separator / reaction chamber (GLS-RC) unit was based on the total liquid phase (sample + acid + NaBH<sub>4</sub>) loaded into it. The constructed unit should provide an appropriate space over the liquid mixture in order to be accomplished the liberation of hydride avoiding the aqueous droplets transportation to the flow-through cell. Experimental observations from previous studies [7, 25, 26] have shown that it takes at least twice the volume of the liquid

1  
2  
3 phase. Thus, the GLS-RC unit was manufactured in our laboratory using a  
4 commercial polyethylene syringe tube (60 mm length, 14.0 mm i.d., 9 mL volume)  
5 and mounted directly on the connector C in vertical position via a push-fit union (Fig.  
6 2). This connector C was adapted at port 4 of the selection valve by a very short (3  
7 cm) and narrow tubing (0.3 mm i.d.) producing a LAV platform offers similar  
8 facilities with a more expensive LOV system.  
9  
10  
11  
12  
13  
14  
15  
16

17 At the top of the GLS-RC, there is another push-fit “T” type union with a  
18 conical cavity and a vertical channel for effective transfer of the evolved arsine vapor  
19 into AAC. The GLS-RC is connected to AAC with PVC tubing (30 cm length, 2.0  
20 mm i.d.). A significant advantage arising from the above configuration is the fact that  
21 the purge gas flows either through the GLS-RC or by-pass it, resulting in  
22 minimization of vapor dispersion as pinpointed elsewhere [25].

#### 40 *Reagents and samples*

41  
42 All chemicals were of analytical reagent grade and ultra-pure quality water from  
43 a Milli-Q system (Millipore, Bedford, USA, www.millipore.com) was used  
44 throughout. Arsenic working standard solutions were prepared by appropriate  
45 stepwise dilution of 1000 mg L<sup>-1</sup> As(III) stock standard solution to the required  
46 concentration levels just before use. The standard solution of 1000 mg L<sup>-1</sup> As(III) was  
47 prepared by dissolving 1.3203 g of As<sub>2</sub>O<sub>3</sub> in 25 mL of 20 % KOH, followed by  
48 neutralization with 20 % m/v sulfuric acid and diluting to 1000 mL with 1 % v/v  
49 sulfuric acid. Sodium tetrahydroborate solution in 0.1 % m/v NaOH were freshly  
50 prepared from NaBH<sub>4</sub> (Fluka, As < 0.000005 % m/m). Hydrochloric acid solutions  
51

54  
55  
56  
57  
58  
59  
60

1  
2  
3 were prepared by adequate dilution of concentrated HCl (Fluka, As < 0.0000005%  
4 m/m, 1.16 g mL<sup>-1</sup>, 32 % m/m). All glassware were cleaned for at least 24 h in 10%  
5  
6 (v/v) nitric acid solution and rinsed with ultra-pure water prior to use. The analyzed  
7  
8 water samples were collected from the Northern Greece region (Axios river, water  
9  
10 supply network of Thessaloniki). The wastewater sample was from a central ditch of  
11  
12 the industrial area of Thessaloniki. All samples were filtered through 0.45 µm  
13  
14 cellulose acetate membrane filter (Millipore), acidified to 0.01 mol L<sup>-1</sup> HCl and stored  
15  
16 at 4°C in polyethylene bottles.

20  
21  
22  
23  
24

#### 25 *On-line operating procedure*

26  
27  
28 The SIA-LAV flow system coupled on-line to HGAAS for inorganic arsenic  
29  
30 determination is presented schematically in Fig. 1 and the operational sequence of the  
31  
32 proposed method is summarized in Table 1. Each analytical cycle started with flowing  
33  
34 of the purge gas through the AAC flow-cell in order to stabilize the baseline. In order  
35  
36 to avoid the dispersion of HCl and sample solutions into the holding coil (HC) during  
37  
38 the loading procedure, a segment (30 µL) of air was interpolated between water and  
39  
40 HCl solution into the HC (step 1). In step 7, a volume of 200 µL of NaBH<sub>4</sub> was  
41  
42 injected rapidly into GLS-RC and the produced nascent hydrogen generated the arsine  
43  
44 vapor. In the following step, valve V2 was actuated to 2-position and the Ar stream  
45  
46 (purge gas) flowed through the GLS-RC to deliver arsine to the AAC for atomization  
47  
48 and quantification. In the next steps (9, 10) the liquid mixture from the GLS-RC was  
49  
50 aspirated into the HC and discarded to waste through port 1. Then, a volume of 4000  
51  
52 µL of water is aspirated into syringe barrel of SP and delivered into GLS-RC through  
53  
54 the HC (steps 11, 12). By these operations both HC and GLS-RC were cleaned from  
55  
56 possible residues of sample or reduction solution. Thereafter, the washings were  
57  
58  
59  
60

1  
2  
3 aspirated into HC and discarded to waste. Considering the recovery and precision tests  
4  
5 of arsenic determination, no sample or reagent carryover problems were observed. Five  
6  
7 replicate measurements were made in all instances.  
8  
9

## 10 11 12 13 **Results and discussion**

### 14 15 16 17 18 19 20 *Study of purge gas flow rate*

21  
22  
23 In hydride generation systems the purge gas flow rate affects the shape of the  
24  
25 transient recorded signal considering its height and width. On the other hand, high  
26  
27 values of the purge gas flow rate can transport droplets of aqueous phase into the  
28  
29 flow-through cell resulting in deterioration of signal reproducibility. The Ar flow rate  
30  
31 was studied within the range of 100 - 300 mL min<sup>-1</sup>. The recorded signal became  
32  
33 narrower with flow rates up to 250 mL min<sup>-1</sup> while for higher flow rates it leveled off.  
34  
35 Thus for higher sensitivity the argon flow rate was fixed to 250 mL min<sup>-1</sup> for further  
36  
37 experiments.  
38  
39  
40  
41  
42  
43  
44

### 45 46 47 *Volume of the liquid mixture*

48  
49 The liquid mixture into the GLS-RC consisted of sample, hydrochloric acid and  
50  
51 sodium tetrahydroborate solutions in various volumes. The large sample volume  
52  
53 results in high sensitivity of the method as it has been reported elsewhere [25]. On the  
54  
55 other hand, the increase of the volume of the liquid mixture affects positively the  
56  
57 solubility of the arsine resulting in the restriction of its release [7]. In order to  
58  
59 facilitate the use of high sample volume, the limited volume of HCl and NaBH<sub>4</sub>  
60

1  
2  
3 solutions were adopted and fixed at 400  $\mu\text{L}$  and 200  $\mu\text{L}$ , respectively, throughout the  
4  
5 experiments. The effect of sample volume on the absorbance was studied in the range  
6  
7 of 1.0 - 3.0 mL using 0.2  $\mu\text{g L}^{-1}$  As(III) standard solution. The results showed an  
8  
9 increase in absorbance by increasing the sample volume, as illustrated in Fig. 3. At  
10  
11 higher volumes the absorbance was increasing with a lower rate due to arsine dilution  
12  
13 in the aqueous phase. The method can be used for sample volume up to 3.0 mL with  
14  
15 proportional sensitivity. Thus, for higher sensitivity, 3.0 mL of sample volume was  
16  
17 adopted as optimum.  
18  
19  
20  
21  
22  
23  
24  
25

#### 26 *Study of acidity and reductant solution*

27  
28

29  
30 The majority of hydride generation methods for inorganic arsenic determination  
31  
32 that are reported in literature make use of a pre-reduction step of arsenate, As(V) to  
33  
34 arsenite, As(III) before the arsine generation procedure. Arsine can be also generated  
35  
36 from As(V) using harsh chemical conditions with a slower reaction rate, than that of  
37  
38 As(III) [7, 27]. For selective As(III) determination, the concentration of hydrochloric  
39  
40 acid and  $\text{NaBH}_4$  solutions were studied using the manifold presented schematically in  
41  
42 Fig. 1. The volumes of HCl and  $\text{NaBH}_4$  solutions were 400 and 200  $\mu\text{L}$ , respectively.  
43  
44  
45  
46

47  
48 The effect of HCl solution on the absorbance was examined in the range 0.5-8  
49  
50  $\text{mol L}^{-1}$  using 1.0 % m/v  $\text{NaBH}_4$  as reductant. The obtained results are presented in  
51  
52 Fig. 4. The absorbance increased rapidly up to 4.0  $\text{mol L}^{-1}$  while for higher  
53  
54 concentrations it remained unchanged. Thus, a concentration of 4.0  $\text{mol L}^{-1}$  HCl was  
55  
56 selected for As(III) determination taking into account that As(V) reduction to arsine  
57  
58 was statistically insignificant at the above HCl concentration.  
59  
60

1  
2  
3 The formation of arsine is completed due to the presence of nascent hydrogen,  
4 which is generated from the decomposition of  $\text{NaBH}_4$  at acidic environment ( $\text{pH} \leq 1$ ).  
5 Decomposition of  $\text{NaBH}_4$  lasts just few  $\mu\text{s}$  [6]. Since  $\text{NaBH}_4$  solution was prepared in  
6 alkaline with  $\text{NaOH}$  solution, the neutralization of the alkalinity should be taken into  
7 account. The effect of the concentration of  $\text{NaBH}_4$  solution on the absorbance was  
8 studied from 0.2 % m/v up to 3.0 % m/v  $\text{NaBH}_4$  using  $\text{HCl}$  solution at  $4.0 \text{ mol L}^{-1}$   
9 concentration level. As shown in Fig. 5, the signal increased by increasing the  
10 concentration of  $\text{NaBH}_4$  up to 1.0 % m/v and leveled off for concentrations up to 1.0  
11 % m/v. Slight decrease was observed for higher concentrations, likely due to the  
12 dilution of the gas phase by great hydrogen generation. Hence, a concentration of 1.0  
13 % m/v  $\text{NaBH}_4$  was selected for the proposed method considering the insignificant  
14 contribution of  $\text{As(V)}$  on the absorbance.

### 35 *Interference studies*

36  
37  
38 On-line vapor generation methods have an inherent advantage related to the  
39 improved tolerance against interferences compared to batch methods [28]. Besides, by  
40 varying  $\text{HCl}$  and  $\text{NaBH}_4$  concentrations, an improvement in the range of interference-  
41 free determination of some typical transition metals can be accomplished during the  
42 arsenic determination [29]. The effect of potential interferences occurring in  
43 environmental water matrices for  $\text{As(III)}$  determination was investigated by analyzing  
44 a standard solution of  $3.0 \mu\text{g L}^{-1}$   $\text{As(III)}$  containing given metal species. A recovery  
45 deviation more than  $\pm 5 \%$  was considered as significant interference. The  
46 experimental results showed that the method could tolerate concentrations of  $\text{Al(III)}$ ,  
47  $\text{Cu(II)}$ ,  $\text{Cr(III)}$ ,  $\text{Fe(II)}$ ,  $\text{Fe(III)}$ ,  $\text{Mn(II)}$  and  $\text{Pb(II)}$  at least up to  $5.0 \text{ mg L}^{-1}$ ,  $\text{Co(II)}$ ,

2  
3 Ni(II), Zn(II) and Sn(II) up to 1.0 mg L<sup>-1</sup>, while Se(IV) can be tolerated up to 1.0 mg  
4  
5 L<sup>-1</sup>. Other common matrix elements such as Ca, Mg, Ba were tolerated at least up to  
6  
7  
8 500 mg L<sup>-1</sup>.  
9

### 10 11 12 13 14 15 *Analytical performance and applications* 16

17  
18 The analytical performance data of the developed SIA-LAV-HG-AAS method for  
19  
20 arsenic determination under the optimized conditions are summarized in Table 2. For  
21  
22 3.0 mL sample consumption the sample frequency was 9 cycles per hour. The  
23  
24 detection limit ( $c_L$ ) based on the 3s criterion (according to IUPAC regulations [30])  
25  
26 was calculated as 3 times the standard deviation of the blank solution measurements  
27  
28 (n = 11) divided by the slope of the corresponding calibration curve was 0.05 µg L<sup>-1</sup>,  
29  
30 and the precision of the method, expressed as relative standard deviation (RSD), was  
31  
32 3.2% at 2.0 µg L<sup>-1</sup> As(III) concentration level. The working linear range varied  
33  
34 between 0.15 to 6.0 µg L<sup>-1</sup> with a good correlation coefficient ( $r$ ) of 0.9994. The  
35  
36 analytical performance of the proposed SIA-LAV-HG-AAS method has been  
37  
38 improved in terms of sensitivity comparing to SIA and multisyringe flow injection  
39  
40 (MS-FI) systems [7, 12, 17] and relatively comparable to other systems using atomic  
41  
42 fluorescence spectrometry [14-16], or ICP-MS [8] as detector. Regarding the  
43  
44 precision, it is better than other MS-FI procedures reported in the literature [14, 17,  
45  
46 18].  
47  
48  
49  
50  
51  
52  
53

54 The accuracy of the proposed method was evaluated by comparing the analytical  
55  
56 results (Table 3) for total arsenic determination in the environmental samples with  
57  
58 those obtained with the conventional on-line FI-HG-AAS using a FIAS-400 flow  
59  
60 injection system in hydride generation mode coupled with atomic absorption

1  
2  
3 spectrometry, which was considered to be reference method. Total inorganic arsenic  
4  
5 was determined after off-line prereduction of As(V) to As(III), in 0.5 % (m/v) KI, 0.5  
6  
7 % (m/v) ascorbic acid, 1.0 mol L<sup>-1</sup> HCl media for 45 min at room. Paired *t*-test was  
8  
9 employed to examine statistically significant differences between the obtained values  
10  
11 of a series of samples using both the proposed and the reference method as described  
12  
13 above. No statistically significant differences were found at 95 % probability level,  
14  
15 since  $t_{\text{exp.}} = 1.9432$  was lower than the  $t_{\text{crit, 95\%}} = 2.4469$ . In addition the batch standard  
16  
17 method 3114 B (Manual Hydride Generation/Atomic Absorption Method) [31] was  
18  
19 employed for comparison purposes. Since the obtained results for total arsenic  
20  
21 determination in the waste water sample were  $12.50 \pm 0.5$  ( $n=3$ ) and  $13.20 \pm 0.9$  ( $n=3$ )  
22  
23 for the SIA-LAV-HG-AAS and 3114 B standard method respectively, the relative  
24  
25 error was 5.3%. In addition, the above mean values were tested by *t*-test at 95%  
26  
27 probability level and was proved that  $t_{\text{exp.}} < t_{\text{crit.}}$  showing that there is no statistically  
28  
29 significant difference between the two methods.  
30  
31  
32  
33  
34  
35

36  
37 The method was applied to the analysis of local natural water samples (river, tap  
38  
39 and mineral water) as well as waste-water samples. The recovery was estimated by  
40  
41 spiking the samples with known amounts of As(III) and As(V). The obtained results  
42  
43 are presented in Table 3. The recoveries were varied in the range 95.5 - 102.5%  
44  
45 showing the good performance of the proposed method for the analysis of  
46  
47 environmental water samples.  
48  
49  
50  
51

53

## 54 55 **Conclusions**

56  
57  
58 A novel automatic sequential injection Lab-At-Valve hydride generation  
59  
60 atomic absorption spectrometry system incorporating a newly designed gas liquid

1  
2  
3 separator coupled with atomic absorption spectrometry has been developed and  
4  
5 optimized for arsenic determination. The GLS-RC was easily constructed with low-  
6  
7 cost materials and placed to one port of the conventional selection valve of a SIA  
8  
9 system, resulting in a more compact and miniaturized manifold. The usefulness and  
10  
11 efficiency of the proposed system was demonstrated for arsenic determination in  
12  
13 environmental water samples revealing good analytical performance characteristics.  
14  
15 The developed method is readily applied to other hydride forming elements without  
16  
17 significant changes.
