A mild and selective Pd-mediated methodology for the synthesis of highly fluorescent 2-arylated tryptophans and tryptophan-containing peptides: a catalytic role for Pd\textsuperscript{0} nanoparticles?\textsuperscript{†}

Thomas J. Williams, Alan J. Reay, Adrian C. Whitwood and Ian J. S. Fairlamb*

A Pd-mediated direct C–H bond functionalisation of tryptophan has been developed, both as a single amino acid residue and within peptides. Important mechanistic insight into this process has been gained by characterising a Pd catalytically competent nanoparticle phase which evolves during the early stages of reaction.

The functionalization and modification of complex biomolecules by the formation of C–C bonds has benefited significantly from the development of mild conditions for Pd-mediated cross-coupling reactions.\textsuperscript{1} Pioneering work by Davis and co-workers has, for example, demonstrated that it is possible to perform Suzuki–Miyaura reactions on proteins containing genetically incorporated aryl iodides.\textsuperscript{2} Metal-mediated direct functionalisation of C–H bonds in complex molecule synthesis is a rapidly expanding field, including in the total synthesis of natural compounds.\textsuperscript{3} We have reported the mild and selective direct C–H functionalisation of highly sensitive purine nucleosides, e.g. adenosine and 2′-deoxyadenosine.\textsuperscript{4} As part of these studies we have been able to gain valuable mechanistic insight, most notably characterising the formation of Pd/Cu-containing nanoparticles during substrate turnover. In this study, we have turned our attention to the mild\textsuperscript{5} C–H bond functionalisation of amino acids,\textsuperscript{6} specifically tryptophan, a hydrophobic indole-containing amino acid which alters the structure and function of proteins, and is a fluorescent marker.\textsuperscript{7}

The C–H bond functionalisation of indoles mediated by Pd is well established.\textsuperscript{8} We recognised that Sanford's methodology\textsuperscript{8} could be applied to selectively functionalise tryptophan, which employs PhB(OH)\textsubscript{2} and PhI(OAc)\textsubscript{2} as reagents, forming diaryliodonium salts \textit{in situ},\textsuperscript{9} and catalytic Pd(OAc)\textsubscript{2}. These reactions could proceed \textit{via} a Pd\textsuperscript{IV} catalytic manifold.\textsuperscript{10} In this paper we detail the selective arylation of tryptophan and tryptophan-containing peptides under mild catalytic conditions.

Sanford’s reaction conditions were initially applied to N-acetyl protected tryptophan 1 to afford, after column chromatography, 2-phenyltryptophan 2 in 56% yield (Fig. 1). Changes to the catalytic conditions included modifying the Pd catalyst and loading, solvent, inert atmosphere and reaction temperature, but no increase in yield was recorded. Optimal turnover numbers and yields were seen between 2.5–5 mol% Pd.

Intriguingly, reaction of 1 with PhB(OH)\textsubscript{2} and PhI(OAc)\textsubscript{2} led to the rapid formation of Pd\textsuperscript{0} nanoparticles (PdNPs) during the first few minutes of the reaction. This finding is in keeping with another Pd-mediated C–H bond functionalisation of benzoxazoles using PhI(OAc)\textsubscript{2}, which we recently reported upon.\textsuperscript{11} The \textit{in situ} generated PdNPs from reaction 1 \textendash; 2a were encapsulated by addition of exogenous polymer stabilizer (\textit{i.e.} polyvinylpyrrolidinone, PVP), which was added to an aliquot of the reaction mixture after 1 h (2.5 mL, containing \sim 4.8 \textmu mol Pd; 10 equiv. PVP added and AcOH removed at 40 °C and ca. 0.750 mmHg). This allows reliable analysis of the size and distribution of the PdNPs without concern that solvent removal leads to metal aggregation. Transmission electron microscopy (TEM) confirmed the presence of the encapsulated PdNPs $n = 100$; average PdNP size is 2.52 nm, represented in Fig. 2.\textsuperscript{12}

Pre-synthesised PVP-PdNPs\textsuperscript{13} (average size \sim 1.8 nm, Pd\textsuperscript{3}, 5 mol%) were also found to be a viable catalytic species for the tryptophan arylation, affording 2a in 57% yield (Fig. 3). This result shows that PdNPs are catalytically competent under the reaction conditions. In the example given in Fig. 1, we propose that the PdNPs are acting as a reservoir for Pd\textsuperscript{0}, akin to related Heck arylation chemistry.\textsuperscript{14} Glorius and co-workers have nicely shown that heterogeneous C–H bond activation is viable in benz\textsubscript{b}thiophene arylation (Scheme 1).\textsuperscript{15}

The reaction of tryptophan 1 with Pd(OAc)$_2$ (1:1) in THF at ambient temperature (0.5 h) was monitored by in situ infrared spectroscopy (Fig. 4). The carbonyl stretching band at 1616 cm$^{-1}$ is Pd(OAc)$_2$, which disappears on addition of 1, with the appearance of a new band at 1606 cm$^{-1}$, proposed to be Pd(OAc)$_2$(1)$_2$. Only small changes were noted by $^1$H NMR spectroscopic analysis, which is in keeping with the tryptophan ligand being weakly coordinated to Pd$^{II}$. Crucially, Pd(OAc)$_2$(1)$_2$ rapidly reduces to form Pd$_0$ and is the seed that leads to the generation of PdNPs under the catalytic conditions – amine ligands lower the Pd$^{II}$ reduction potential to give Pd$_0$ ions.4

Following this study, some limitations were revealed in terms of the substrate scope using Pd(OAc)$_2$ as the precatalyst.‡ For example, a simple switch from PhB(OH)$_2$ to 4-MeC$_6$H$_4$B(OH)$_2$ led to the biaryl compound derived from the latter only {PhI(OAc)$_2$ could be aiding oxidative homocoupling of the aryl boronic acid}.16 Simply switching the oxidant to Cu(OAc)$_2$ afforded 2a in 93% yield (under the conditions described in Fig. 5). Here, Cu(OAc)$_2$ is assisting the reoxidation of Pd$_0$ (with O$_2$ from air). This was confirmed by conducting the same reaction under an Ar atmosphere, which showed ~11% conversion to 2a, i.e. a single turn-over of the Cu$^{II}$ co-catalyst. A series of analogues (2b–2d) were formed in good yields using this procedure. The electron-rich $p$-anisoyl boronic acid was susceptible to oxidative homocoupling, leading to 2e being formed in modest yield, expected under oxidative conditions.

The specific optical rotations of the products, and analysis by chiral HPLC, indicated that the arylated tryptophan products maintained their stereochemical purity (see ESI‡). Single crystal X-ray diffraction structures for analogues 2c and 2d (Fig. 6), confirm absolutely their structural connectivity. The data shows in the solid-state that the aryl and indole groups deviate from planarity, which is likely a crystal packing effect. The conformational preference of the ester, amino and aryl moieties could affect the intrinsic fluorescence properties and provide a useful starting point for future TDDFT calculations.

UV-vis and fluorescence measurements reveal the effect of the different aryl groups within the tryptophan framework (Fig. 7). The most electronically distinct analogues, 2d (4-CF$_3$) and 2e (4-OMe), exhibit the highest absorption shifts, generating a characteristic V-shape. Such a correlation has been reported by Marder and co-workers in 1,4-bis ($p$-R-phenylethynyl)benzenes and 2,5-bis(phenylethynyl) thiophenes, and could be an indication of a push–pull type system within the series 2a–e.17 The largest fluorescence intensity is seen for 2a – the other compounds...

known that certain peptides template (by reduction) the formation of specifically-sized and shaped PdNPs. These aspects pertaining to C–H bond functionalisation are currently being investigated within our laboratories.

The authors would like to thank Dr Meg Stark (Department of Biology, University of York) for transmission electron microscopy. We are grateful to Mr Henry Durant for exploratory reaction optimisation. We also thank the EPSRC for funding (DTA PhD studentship for J.T.W., grant code EP/P50178/1). The Royal Society is thanked for funding a University Research Fellowship (I.J.S.F.).

Notes and references

‡ As PdNPs are formed rapidly in this chemistry, we define Pd(OAc)₂ as a precatayst.

9 We have established that the reaction of 1 with d₅-PhB(OH)₂ and PhI(OAc)₂ affords a mixture of deuterated and non-deuterated 2-phenyl-tryptophan 2a in a ca. 1:1.5 ratio (by MS studies).
12 Unsupported PdNPs were characterised at a similar size (±0.3 nm) – see ESI ‡ for TEM images.
