This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Synthesis and Characterization of different Nanostructured Copper(II) Metal-organic Frameworks by Ligand Functionalization and Modulation Method

Mohammad Amin Alavi, Ali Morsali

Nanorods of $\{[Cu_2(BDC)]_2(dabco)].2DMF.2H_2O\}$ (1) and Nanotubes $\{[Cu_2(BDC-NH_2)]_2(dabco)].2DMF.2H_2O\}$ (2) have been synthesized via reaction of copper(II) acetate with terephthalic acid and aminoterephthalic acid, in presence of triethylenediamine as pillar ligand and acetic acid as modulator, respectively. Formation of the unexpected nanotubes morphology instead of nanorods was evidenced when amino benzene-1,4-dicarboxylate [BDC-NH$_2$] was used instead of benzene-1,4-dicarboxylate (BDC) ligand. Nanorods and Nanotubes of compounds 1 and 2 were characterized by scanning electron microscopy (SEM), transmission electron microscopy (TEM), X-ray powder diffraction (XRD) and BET analyses.

Introduction

Well-designed porous coordination polymers (PCPs) or metal–organic frameworks (MOFs) are produced by assembly of organic linkers with metal ions. Their well-defined porosity and tunable chemical functionality make them extremely attractive for applications in gas storage, catalysis and separation. Reducing the size of PCP crystals to nanometer scale via functionalization of the crystal interfaces will provide further opportunities to integrate novel functions without changing characteristic features of the parent PCP crystal. Besides, it will allow correlation between porous properties and interfacial structures of nanocrystals to be investigated. Despite the advantages of nano PCPs, growth processes responsible for establishment of universal methodology are still unclear because there is no suitable defining protocol. In this regard, understanding crystal growth of framework materials, promises to determine the fundamental requirements for bottom-up self-assembly processes.

Formation of $\{[Cu(ndc)(dabco)]_{0.5}\}$ nanocrystals through reaction of ndc=1,4-naphthahale dicarboxylate and dabco=1,4-diazabicyclo[2.2.2]octane in presence of acetic acid as modulator was previously reported by Kitagawa et al. Zhang and co-workers have synthesized nanoscale Ln(BTC)(H$_2$O)$_n$, where Ln = Dy$^{3+}$, Eu$^{3+}$, or Tb$^{3+}$ and BTC = 1,3,5-benzenetricarboxylate, using sodium carboxylates (sodium formate, sodium acetate, or sodium oxalate) as capping agents to control crystal size and morphology. However in these reports the linker were carboxylate ligand with no functional groups or substitutes and only the effect of modulator or capping agent on MOF growth mechanism have been investigated. In this work, modulation method is used to prepare one dimensional nanorods of $\{[Cu_2(BDC)(dabco)].2DMF.2H_2O\}$ (1) and nanotubes of $\{[Cu_2(BDC-NH_2)(dabco)].2DMF.2H_2O\}$ (2) where BDC= benzene-1,4-dicarboxylate and BDC-NH$_2$= amino benzene-1,4-dicarboxylate. Interestingly, replacing BDC ligand with BDC-NH$_2$ changes the morphology from nanorod to nanotube.

Experimental

Materials and Physical Techniques

All reagents and solvents for the synthesis and analysis were commercially available from Merck and used as received. X-ray powder diffraction (XRD) measurements were performed using an X`pert diffractometer of Philips Company with mono chromatized Cuku radiation. The samples were characterized with a scanning electron microscope (SEM) (Philips XL 30) with gold coating and also a transmission electron microscope (TEM) (LEO912AB) at an accelerating voltage of 120 kV. FTIR spectra were recorded using Perkin-Elmer 597 and Nicolet 510P spectrophotometers and BET (Brunauer-Emmett-Teller) surface area of the samples were determined from $N_2$ adsorption–desorption isotherms using a Surface Area Analyzer (BELSORP).
General procedure for synthesis of compounds 1 and 2
Nanotubes and nanorods of PCP \([\text{Cu}_2(\text{BDC})(\text{dabco})]_2\text{DMF} \cdot 2\text{H}_2\text{O}\) (1), \([\text{Cu}_2(\text{BDC-NH}_2)(\text{dabco})]_2\text{DMF} \cdot 2\text{H}_2\text{O}\) (2) were prepared by the coordination modulation method. A solution of \(\text{Cu(OAc)}_2 \cdot \text{H}_2\text{O}\) (0.06 M) and \(\text{CH}_3\text{COOH}\) (0.6 and 1 M) in DMF was heated at 100ºC in a two-necked flask. When the temperature of the solution reached to 100ºC, \(\text{H}_2\text{BDC-NH}_2\) or \(\text{H}_2\text{BDC}\) (0.63 mmol) and \(\text{dabco}\) (0.035 mmol) was added to the solution (Table 1). After the reaction had run for 24 h, the resulting samples were filtered through a glass microfiber filter, washed with DMF several times, and dried using a vacuum pump.

Anal. calc. for compound 1: C, 44.58; H, 5.04; N, 7.43; found: C, 46.07; H, 4.66; N, 7.05% and anal. calc. for compound 2: C, 42.87; H, 5.01; N, 10.7; found: C, 43.84; H, 4.18; N, 9.96%.

To confirm the effect of modulator reagent (acetic acid) on the morphology and crystal sizes of PCP a sample was prepared in the reaction conditions of \([\text{Cu}_2(\text{BDC})(\text{dabco})]_2\text{DMF} \cdot 2\text{H}_2\text{O}\) (1) and \([\text{Cu}_2(\text{BDC-NH}_2)(\text{dabco})]_2\text{DMF} \cdot 2\text{H}_2\text{O}\) (2) in the absence of acetic acid.

**Table 1:** Experimental condition to prepare \([\text{Cu}_2(\text{BDC})(\text{dabco})]_2\text{DMF} \cdot 2\text{H}_2\text{O}\) (1) nanorods and \([\text{Cu}_2(\text{BDC-NH}_2)(\text{dabco})]_2\text{DMF} \cdot 2\text{H}_2\text{O}\) (2) nanotubes.

**Results and discussion**

To confirm the preparation of MOFs with paddle-wheel motifs, X-ray powder diffraction and elemental analyses are performed. Both compounds 1(Nanorod) and 2(Nanotube) have very similar PXRD patterns with the reported isostructure compounds, \([\text{Zn}_2(\text{bdc})(\text{ted})]_2\text{DMF} \cdot 0.2\text{H}_2\text{O}\) and \([\text{Zn}_2(\text{BDC-NH}_2)(\text{ted})]_2\text{DMF} \cdot \text{yH}_2\text{O}\) (Figure 1) confirming that the pillared 3D structure is retained upon ligand functionalization. So, modulation method does not change the phase and structure in compounds 1 and 2. For each MOF these analyses were done in the presence of 0.6 and 1 M of acetic acid (Figure 2). As it can be seen, in compound 2, by replacing BDC with BDC-NH\(_2\) crystalinity is reduced. Besides, in compound 1, by increase the acetic acid concentration from 0.6 to 1 M, crystalinity reduces but in compound 2 crystallinity increases. It seems that interactions of acetate ions with amino groups blocks them, improves the crystalinity, and affects growth of motifs in one-dimensional.

TEM analysis was used to investigate growth of the unexpected nanotubes. As expected, in the presence of 0.6 M and 1 M acetic acid for samples No 1 and 2, respectively, nanorods of compound 1 are prepared (Figure 3a-d). Replacing BDC with BDC-NH\(_2\) (compound 2) the morphology is changed to nanotubes (Figure 3e-h). To investigate the role of modulator on the morphology of
compound 2, three further experiments (samples No. 7, 8 and 9) were done. Comparison of the TEM images of samples No. 4 and 7 (Figures 3e,f and 4a,b, respectively) shows that by decreasing the concentration of metal ions and linkers a few nanotubes has been prepared. As it can be seen in Figure 4 c,d there is no sign of nanotubes in prepared compound 2 by decreasing the concentration of modulator till 0.3 M (Sample No.8). Figure 4e,f shows TEM images of sample No. 9 and confirms that increasing or decreasing the concentration of metal ions and linkers has the same results and a few nanotubes has been growth in these conditions.

Figure 3 illustrates the similarity in diameters of nanotubes and nanorods, confirming the influence of ligands on structure of MOF and showing that the synthesis conditions are optimized for both of the systems. Comparing of the TEM images confirm that a small change in the linker, from BDC to BDC-NH₂, affects the morphology. Preparation of one-dimensional nanorods in the presence of modulator reagents was explained earlier by Kitagawa et al. In fact, acetic acid has functionalities similar to dicarboxylate linker and the competition between them leads to production of one-dimensional nanorods of MOFs. The nanorods grow by the oriented attachment of the nanocubes by collision of nanocubes in solution. The mechanism of anisotropic crystal growth is clearly explained by oriented attachment. The coordination modulation method affords perfect framework regularity in PCP nanocrystals, which allows the nanocrystals to be applied as crystalline porous materials. Furthermore, functionalization of the dicarboxylate linker by amino group in this investigation opens up a new way to prepare the nanotubes of the same MOFs. It seems that amino groups interfere during self-assembly of MOFs and lead to production of nanotubes.

Figure 3. TEM analysis of samples No. a, b) 1, c,d) 2, e,f) 4 and g,h) 5.

Figure 4. TEM images of samples a,b) No.7, c,d) No.8 and e,f) No.9.

Figure 5 shows SEM images of samples No. 1-8. As we expected in the presence of modulator reagent (samples No.1, 2, 4 and 5) nanostructures were grown and separated but in the absence of modulator reagent (samples No. 3 and 6) agglomeration of particles has been prepared.

Figure 5 shows SEM images of samples No. 1-8. As we expected in the presence of modulator reagent (samples No.1, 2, 4 and 5) nanostructures were grown and separated but in the absence of modulator reagent (samples No. 3 and 6) agglomeration of particles has been prepared.
Adsorption of $\text{N}_2$ is studied for both the nanorods of compound 1 and nanotubes of compound 2 to analyze porosity based on Brunauer-Emmett-Teller (BET) method. Comparing of the adsorption isotherms corresponding to highly crystalline nanorods of compound 1, nanotubes of compound 2, prepared with 0.6 M acetic acid, and less-crystalline aggregated crystals, prepared in absence of acetic acid, clearly indicates that nanorods are the superior sorbers of nitrogen (Figures 7). The competitive interaction of the BDC–copper or BDC-NH$_2$–copper and the acetate–copper is essential to reduce the rate of framework construction. This allows anisotropic growth of nanocrystals and formation of MOF structures with high crystallinity. The lower sorption amount of the aggregated crystals is most likely attributed to the lower crystallinity and critical number of defects which allow blocking of the channels. The adsorption branches are completely flat up to $p/p^o = 0.8$ discarding the occurrence of such a porosity. The prepared materials are therefore essentially microporous. The hysteresis loop observed is likely due to some interparticular voids which desorb at low pressure, that is $p/p^o = 0.42$. Moreover, the isotherm $b$ looks like type IV, not type I. This may be attributed to the presence of the nanotubes which provides some mesoporosity in the compound 2.

The pore size distributions for samples No.1, 3 and 4 are shown in Figure 8. For compound 1 and 2 one peak is observed at 6 Å, indicating that the obtained MOFs have uniform micropores.

Thermal gravimetric analysis of compounds 1 and 2 is illustrated as Figure 9. As it can be seen for compound 1, three major losing weights at 145, 250, 350 °C are due to DMF+ H$_2$O (17%), dabco (14%), and terephthalic acid (43%), respectively. The results are the
same for compound 2 but weight losses occur at different temperatures, i.e. at 145°C DMF and H$_2$O (16%), and dabco (13%) and NH$_2$-BDC (46%) at 250°C and 290°C, respectively. So the results are in agreements with structural formula of \([\text{Cu}_6\text{BDC}](\text{dabco})\cdot2\text{DMF}.2\text{H}_2\text{O}\) for compound 1 and \([\text{Cu}_6\text{BDC-NH}_2\text{BDC}](\text{dabco})\cdot2\text{DMF}.2\text{H}_2\text{O}\) for compound 2.

**Conclusions**

One-dimensional nanostructure, i.e. nanorods and nanotubes, of compounds \([\text{Cu}_6\text{BDC}](\text{dabco})\cdot2\text{DMF}.2\text{H}_2\text{O}\), (1) and \([\text{Cu}_6\text{BDC-NH}_2\text{BDC}](\text{dabco})\cdot2\text{DMF}.2\text{H}_2\text{O}\), (2) have been synthesized via modulation method. Formation of the unexpected nanotubes morphology instead of nanorods was evidenced when amino benzene-1,4-dicarboxylate \(\text{BDC-NH}_2\) was used instead of benzene-1,4-dicarboxylate \(\text{BDC}\) ligand. This investigation shows that by functionalizing the linker with amino group in presence of modulator, the morphology changes from one-dimensional nanorods to nanotube. This is the first report for preparation nanotube of \([\text{Cu}_6\text{BDC-NH}_2\text{BDC}](\text{dabco})\cdot2\text{DMF}.2\text{H}_2\text{O}\), (2) by modulation method.
