This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Reactivity studies of a soluble LiH-complex and non-spectator behaviour of its stabilising phosphinoamide ligand

Andreas Stasch*

Table of contents entry

*TOC preferred: The reactivity of a soluble phosphinoamide stabilized lithium hydride complex towards some unsaturated organic substrates is described and hydrolithiation and phosphinoamide addition products are reported.
Reactivity studies of a soluble LiH-complex and non-spectator behaviour of its stabilising phosphinoamide ligand†

†Electronic supplementary information (ESI) available: For crystallographic data in CIF and further details see CCDC 948283-948287. For ESI and crystallographic data in CIF or other electronic format see DOI: 10.1039/cxxxxxxx.

We have investigated and compared the reactivity of the phosphinoamido stabilized hydrocarbon-soluble LiH complex [(LLi)₄(LiH)₄] 1 (L = [Ph₂PNDip], Dip = 2,6-iPr₂C₆H₃) and the lithium phosphinoamide [LLi] 2, respectively, towards some unsaturated organic substrates. The complexes [(LiMe₂OLi)(DCCLi)₂] 3 (DCC = CyNCNCy, Cy = cyclohexyl), and [(HDCC)₆Li₈O] 4 were obtained from reactions of 1 with DCC, and the complexes [{(LN(Ph)N(Ph)Li)}₂] 5 and [{PhN(Li)-N(Li)Ph}₄] 7 were obtained from reactions of 1 with azobenzene. Complex 5 was furthermore obtained in good yield from 2 and azobenzene, and was converted to the solvate [(LN(Ph)N(Ph)Li)(THF)] 6. Complex 7 could be independently synthesized from lithium metal and azobenzene. Complex 1 undergoes hydrolithiation reactions with some substrates, as evidenced by the formation of complexes 3, 4, and indirectly by 7, but also takes part in addition reactions of the stabilizing phosphinoamide ligand onto substrates as shown by the isolation of complexes 3 and 5. The crystals structures of complexes 3, 5, 6, 7 and [LLi(THF)]₃ are reported.
Introduction

Metal hydrides from elements across the periodic table show very different properties and polarity of their hydrogen atoms.\textsuperscript{1} Metal hydrides of the s-block metals, \textit{i.e.} group 1 and 2 of the periodic table except hydrogen, are predominantly saline hydrides with dominant M\textsuperscript{m+}\textcdots H\textsuperscript{n-} ionic interactions and generally have large lattice energies for their parent solids.\textsuperscript{2,3} Well-defined molecular metal-hydride complexes of the s-block metals and their further chemistry\textsuperscript{2} is still underrepresented compared with those from other parts of the periodic table, despite a great interest for potential wide-spread uses in synthesis, catalysis and hydrogen storage applications. This area of chemistry has, however, recently gained popularity because suitable stabilizing ligands are being studied and convenient synthetic routes into s-block metal hydride fragments are now available.\textsuperscript{2} Amongst them, the silane method is convenient and most widely used.\textsuperscript{2,4} Here, a metal alkyl or amide fragment reacts with a silane, often commercially available phenylsilane, PhSiH\textsubscript{3}, to form a metal hydride fragment and a substituted silane in a metathesis reaction, according to the general equation (1); R = alkyl or substituted amide, [M] = s-block metal complex fragment.

\begin{equation}
[M]R + \text{PhSiH}_3 \rightarrow [M]H + \text{PhSiH}_2R
\end{equation}

Suitable stabilizing ligands that chelate and/or sterically protect, and thus generally kinetically stabilize the metal hydride complex from decomposition reactions, are crucial for the development of well-defined complexes. These suppress or prevent the decomposition via ligand rearrangement reactions and the generally favoured precipitation of insoluble inorganic metal hydrides, \textit{i.e.} MH or MH\textsubscript{2}, with high lattice energies.

Most structurally characterized examples of s-block metal hydride complexes feature ligand stabilized metal hydrides involving the group 2 metals, mainly magnesium.\textsuperscript{2} Much less is known about well-defined molecular group 1 metal hydride complexes, and some rare Li\textsuperscript{1} cluster complexes with interstitial hydride\textsuperscript{5,6} and the structurally characterized superaggregate [(\textit{tBuOLi})\textsubscript{16}(LiH)\textsubscript{17}]\textsuperscript{7} have been reported. Recently, we used the new sterically demanding phosphinoamide (phosphanylamide)\textsuperscript{8} [Ph\textsubscript{2}PNDip]\textsuperscript{-} (Dip = 2,6-\textit{i}Pr\textsubscript{2}C\textsubscript{6}H\textsubscript{3})\textsuperscript{1}, in the stabilization of the novel hydrocarbon-soluble LiH complex [(L\textit{Li})\textsubscript{4}(LiH)\textsubscript{4}]\textsuperscript{1} I, see Chart 1, which was prepared from the mixed phosphinoamido alkyl complex [L\textsubscript{2}Li\textsubscript{4}nBu\textsubscript{2}] and phenylsilane according to eq. (1), and studied its properties and reactivity towards benzophenone.\textsuperscript{9} Very recently, we have extended this synthetic concept to isolate well-defined pyrazolato-stabilised hydride rich LiH clusters with inorganic cores in the nanometer region, for example [(pz)\textsubscript{12}Li\textsubscript{37}H\textsubscript{25}] and [Li(THF)\textsubscript{4}][(pz)\textsubscript{12}Li\textsubscript{37}(THF)\textsubscript{2}H\textsubscript{26}] (pz = 3,5-di-\textit{tert}-butylpyrazolate).\textsuperscript{10}
Results and Discussion

Previously, we found that the hydrolithiation of benzophenone, Ph$_2$C=O, using the hydrocarbon-soluble LiH complex [(LLi)$_4$(LiH)$_4$] 1, yields [(Ph$_2$CHO)Li]$_6$ in good yield based on the LiH content of 1. The good isolated yield could be obtained because the product readily crystallises from the reaction solution. Here we extent our investigation of [(LLi)$_4$(LiH)$_4$] 1 towards other unsaturated organic substrates, and compare the outcomes with those of the related hydride free phosphinoamide lithium complex [LLi] 2, the latter complex being only poorly soluble in uncoordinating solvents likely due to an oligomeric or polymeric nature.

The reaction of [(LLi)$_4$(LiH)$_4$] 1 with Ph$_2$C=CH$_2$ or PhC≡CPh, respectively, at room temperature showed no reaction as judged by solution $^1$H and $^{31}$P{$^1$H} NMR spectroscopy. At elevated temperature of approximately 60°C and above, complex 1 starts to slowly decompose into poorly soluble [LLi] 2 and by implication LiH, as previously reported. Product mixtures have consequently been obtained for these reactions at elevated temperatures and no reaction of the two substrates with the LiH content of 1 was apparent, though some conversion involving freshly released LiH during the decomposition can’t be excluded and would be difficult to spectroscopically detect amidst large quantities of 1 and 2. From one of these reactions, we obtained a crop of yellow [LLi(THF)$_3$] after recrystallization from THF and both structural (see the electronic supplementary information, ESI) and spectroscopic data (see the experimental section) are similar to those previously found for [LLi(THF)$_2$]. Similarly, the reaction of 1 with 1,1-diphenylfulvene showed no reaction at room temperature and at elevated temperatures a product mixture is obtained according to $^1$H and $^{31}$P{$^1$H} NMR spectroscopy, that doesn’t permit a conclusion on the formed products.

The reactions of [(LLi)$_4$(LiH)$_4$] 1 with ca. four to eight equivalents of dicyclohexylcarbodiimide (DCC) in deuterated benzene at room temperature afforded light yellow product mixtures, see the ESI for $^1$H (Fig. S1) and $^{31}$P{$^1$H} (Fig. S2) NMR spectra. The $^{31}$P{$^1$H} NMR spectrum (Fig. S2) of
a typical example shows several new broadened resonances between δ0-5 ppm and a broadened resonance at δ60.8 ppm. The latter is likely attributed to a DCC donor-stabilised phosphinoamide lithium complex, in comparison with very similar chemical shifts for THF and TMEDA adducts of [LLi]$_2$. Similar $^1$H (Fig. S3) and $^{31}$P{$^1$H} (Fig. S4 and S5) NMR spectra were found for the reaction of [LLi]$_2$ with DCC, including very similar broad resonances around δ0-5 ppm ($^{31}$P{$^1$H} NMR). These suggest that phosphinoamide additions to DCC occur likely forming substituted lithium guanidinate or phospha(V)guanidinate species. The $^1$H NMR spectra for both reactions suggest a mixture of compounds had formed and an additional strong singlet at δ7.94 ppm (Fig. S1) is found for the reaction involving 1, along with partial consumption of the broad LiH resonance at δ4.18 ppm. The former singlet is neither found in the reaction of 2 with DCC (Fig. S3) nor in the spectrum of compound 1$^9$ and very likely shows the formamidinate$^{12}$ hydrogen in a HDCCLi fragment from the hydrolithiation of LiH fragments with DCC, see the simplified scheme 1. The chemical shift is similar to those found for some related dicyclohexylformamidinate lithium complexes, e.g. δ7.16 ppm (in C$_6$H$_6$),$^{13}$ and δ7.81 ppm (in THF-d$_8$).$^{14}$

Scheme 1 hydrolithiation of DCC

Isolation and separation attempts by crystallization from the latter experiment afforded some small colourless needles of the formamidinate aggregate [(LSiMe$_2$OLi)$_2$(HDCCLi)$_2$]$_3$, see Fig. 1, that were characterized using synchrotron radiation. [(LSiMe$_2$OLi)$_2$(HDCCLi)$_2$]$_3$·3 C$_6$H$_6$ crystallized with a full molecule in the asymmetric unit. The product can be described as having a central distorted Li$_4$ tetrahedron (dashed lines in Fig. 1) with two monoanionic substituted phosphino amido silanolate ligands and two HDCC-formamidinate ligands. The silanolate groups cap two of the four Li$_3$ tetrahedron faces with their $\mu_3$-O atom and the neutral silylamido phosphine moieties coordinate to one Li centre each. The two formamidinate ligands similarly coordinate to two of the Li$_3$ tetrahedron faces, albeit with a $\mu_3$-$\kappa^1N;2:3\kappa^2'N'$ coordination mode. The C-N bond lengths of the formamidinate backbone are somewhat localized and the shorter ‘amido’ C-N ones (N(5)-C(53): 1.303(2), N(6)-C(66): 1.3048(19)) belong to the $\kappa^1N$ nitrogen coordination with the shortest Li-N distances.

The product incorporates both the formamidinate ligand formed via hydrolithiation, see scheme 1, and also a phosphinoamide-silicone addition product (see below, scheme 3). Incorporation of silicone units from silicone grease polymers into organometallic and related compounds has often
been described.\textsuperscript{15} Here, the addition of the phosphinoamide ligand onto a Me_2SiO moiety via N-attack is observed with a newly formed N-Si bond. Since complex 3 contains Me_2SiO fragments from the silicone grease polymer, some separation and crystallisation experiments were carried out in grease-free glassware. After some attempts, a small crop of crystals of known cubic [(HDCC)$_6$Li$_8$O] \textsuperscript{4,13} crystallised from hexane with an interstitial oxide ion, was obtained and structurally characterized, amongst some oily products that couldn’t be purified. The central oxygen atom in 4 likely originates from trace amounts of air or moisture during recrystallization. Isolation attempts for reactions of [LLi] 2 with DCC only led to oily product mixtures that couldn’t be separated.

![Molecular structure of compound 3·3 C_6H_6 (30% probability thermal ellipsoids).](image)

**Fig. 1** Molecular structure of compound 3·3 C_6H_6 (30% probability thermal ellipsoids). Hydrogen atoms and solvent molecules have been omitted for clarity. Selected bond lengths (Å) and angles (°): P(1)-N(1) 1.7160(15), P(2)-N(2) 1.7148(13), P(1)-Li(1) 2.651(3), P(2)-Li(4) 2.624(3), Si(1)-O(1), 1.6005(11), Si(2)-O(2) 1.6004(11), Si(1)-N(1) 1.7807(14), Si(2)-N(2) 1.7767(13), O(1)-Li(3) 1.907(3), O(1)-Li(1) 1.921(3), O(1)-Li(4) 1.993(3), Li(1)-O(2) 1.934(3), Li(1)-N(4) 2.132(3), O(2)-Li(2) 1.896(3), O(2)-Li(4) 1.921(3), Li(2)-N(6) 1.938(3), Li(2)-N(4) 2.041(3), Li(3)-N(5) 1.952(3), Li(3)-N(7) 2.070(3), Li(4)-N(7) 2.135(3), N(4)-C(53) 1.3384(19), N(5)-C(53) 1.303(2), N(6)-C(66) 1.3048(19), N(7)-C(66) 1.338(2); P(1)-N(1)-Si(1) 116.46(8), P(2)-N(2)-Si(2) 117.49(7), Li(3)-O(1)-Li(4) 79.76(12), Li(1)-O(1)-Li(4) 81.96(11), Li(3)-O(1)-Li(1) 96.93(12), N(5)-C(53)-N(4) 125.10(13), N(6)-C(66)-N(7) 125.30(14).
The reaction of a solution of [(LLi)$_4$(LiH)$_4$] 1 with varying amounts of azobenzene, PhN=NPh, was followed by $^1$H and $^{31}$P{$^1$H} NMR over three days, see Fig 2 for a partially assigned $^1$H and $^{31}$P{$^1$H} NMR spectrum after 16 h, and the ESI (Fig. S6-S9). The reaction changed colour from orange via green to brown-yellow over the course and a product mixture was obtained that shows two main broad resonances at $\delta$ 19.7 and $\delta$ 22.5 ppm in the $^{31}$P{$^1$H} NMR spectrum and broad resonances for the iPr methyl and methine protons in the $^1$H NMR spectrum. A sharp singlet at $\delta$ 4.46 ($^1$H NMR)$^{14}$ for dihydrogen is also found. For comparison, the reaction of poorly soluble [LLi] 2 with approximately one equivalent of azobenzene is surprisingly faster and shows a very similar outcome, namely the domination of the same broad resonances in $^1$H and $^{31}$P NMR spectra (ESI, Fig. S10 and S11) as compared to the same reaction involving 1, albeit with no observed H$_2$ formation. The new product [{(LN(Ph)N(Ph)Li)$_2$}] 5, could be isolated as colourless crystals from both reaction mixtures in moderate to good yields, see Fig. 3 (and see scheme 3 below).
Fig 2. $^1$H NMR (400.17 MHz) spectrum (top) and $^{31}$P{$^1$H} NMR (161.98 MHz) spectrum (bottom) of the in-situ reaction of [(LLi)$_4$(LiH)$_4$] 1 with PhN=NPh at room temperature after ca. 16 h in deuterated benzene recorded at 303 K showing partial conversion to [{(LN(Ph)N(Ph)Li}$_2$] 5. $^1$H: #: PhN=NPh resonances; *: H$_2$; +: characteristic resonances of [(LLi)$_4$(LiH)$_4$] 1; >: selected
resonances of \([\{(LN(Ph)N(Ph)Li)\}_2]\) 5; § toluene resonance. \(^{31}\)P\(^{\{1\}H}\): %: small amounts of a DCC donor-stabilised Ph\(_2\)PN(Dip)Li species; $: small amounts of Ph\(_2\)PN(H)Dip; 1: \([(LLi)_4(LiH)_4]\) 1; 5: \([\{(LN(Ph)N(Ph)Li)\}_2]\) 5.

**Fig. 3** Molecular structure of compound 5 (30% probability thermal ellipsoids). Hydrogen atoms have been omitted for clarity. Selected bond lengths (Å) and angles (°): P(1)-N(1) 1.5648(14), P(1)-N(2) 1.6845(14), N(1)-Li(1) 1.943(3), Li(1)-N(3) 2.020(3), Li(1)-N(3)’ 2.035(3), N(2)-N(3) 1.4439(19), N(3)-Li(1)’ 2.035(3); N(1)-P(1)-N(2) 106.95(7), N(3)-N(2)-P(1) 115.49(10), N(1)-Li(1)-N(3) 90.35(13), N(1)-Li(1)-N(3)’ 134.78(18), N(3)-Li(1)-N(3)’ 107.89(14); symmetry transformations: ‘1 -x+1,-y,-z.

Isolated compound 5, see Fig. S12 and S13 for \(^1\)H and \(^{31}\)P\(^{\{1\}H}\) NMR spectra, shows the broadened \(^1\)H NMR \(i\)Pr resonances and the two broad \(^{31}\)P NMR resonances at 30°C previously observed from in-situ experiments, see Fig 2 and S8-S11, and only shows one broad resonance at \(\delta\) 21.0 ppm (\(^{31}\)P\(^{\{1\}H}\) NMR) at 60°C (Fig. S13), and the \(^1\)H NMR spectrum now shows one broad resonance for the \(i\)Pr methyl protons and a sharp septet (\(\delta\) 3.44 ppm) for the \(i\)Pr methine protons at this temperature (Fig. S12). One broad resonance is observed for 5 in its \(^7\)Li\(^{\{1\}H}\) NMR spectrum. Complex 5 crystallizes with half a molecule in the asymmetric unit and shows an addition product of the phosphinoamide lithium complex and azobenzene with newly formed P-N bond that forms a dimeric aggregate via Li···N interactions. The newly formed fragment is a monoanionic, chelating...
ligand that forms a five-membered ring with its lithium countercation. The P1-N1 bond lengths (1.5648(14) Å) suggests a predominantly iminophosphorane description and the significantly longer P1-N2 bond lengths (1.6845(14) Å) supports a formulation as a single bond (see scheme 3 below). The Li cation is three-coordinated (sum of angles 333.0(5)°) plus shows short contacts to \(^3\)Pr hydrogens, the shortest being ca. 2.55 Å. N2 is close to planar three-coordinate (sum of angles 358.3(5)°) and is singly bonded (1.4439(19) Å) to N3 with a C-N-N-C torsion angle of ca. 78°. Recrystallization of a sample of 5 from \(n\)-hexane/THF afforded a crop of the structurally similar monomeric mono-THF adduct [(LN(Ph)N(Ph)Li(THF))] 6, see Fig. S15. Complex 6 crystallizes with a full molecule in the asymmetric unit. The structure represents one half of molecule 5 plus one THF molecule coordinating to the Li ion resulting in a three-coordinate environment. The coordination of the Li centre is somewhat asymmetric and the N-Li-O angle for the anionic hydrazide is much larger (143.9(2)°) than that involving the neutral iminophosphorane donor (118.8(2)°). The Li coordination is also not fully planar (sum of angles 355.6(6)°) and is partially distorted by short contacts to \(^3\)Pr-hydrogens; the shortest is a methine-C–H···Li contact of ca. 2.35 Å. The \(^1\)H NMR spectrum of 6 shows somewhat broadened resonances comparable to 5 that sharpen at elevated temperature and show one sharp septet at 70°C for the \(^3\)Pr methine protons and a broad resonance for the \(^3\)Pr methyl protons. The \(^{31}\)P{\(^1\)H} NMR spectrum shows one broad resonance at \(\delta\) 10.3 at 30°C.

To further investigate the fate of the LiH moieties in the reaction of 1 with azobenzene and the source of the dihydrogen, we tried to separate further products from the reaction mixture. We obtained yellow crystals of [([PhN(Li)-N(Li)Ph]₄) 7·6 C₆H₆ that were structurally characterized using synchrotron radiation, see Fig. 4. Complex 7 crystallizes with half a molecule in the asymmetric unit and consists of four PhN(Li)-N(Li)Ph units that form a central inorganic cage of four Li and eight N atoms plus four outer ‘terminal’ Li atoms. The former azobenzene N=N double bonds in 7 are now reduced to Ph-N-N-Ph\(^2\)-units that show long N-N single bonds of 1.466 Å and 1.469 Å. The two phenyl groups of each substituted hydrazine-1,2-diide are twisted relative to each other around the long N-N bond by ca. 92-93°, as measured from their C-N-N-C torsion angles. The inner cage comprises four N,N,Li,N,N,Li six-membered rings and two N,Li,N,Li four-membered rings. Each N atom is connected to a phenyl group and one neighbouring N atom, and coordinates to two Li atoms, both with different coordination environments. The four ‘inner’ Li atoms coordinate to three N atoms each and the four outer ‘terminal’ Li atoms coordinate only to one N atom, plus to two phenyl groups with short \(\eta^6\) and approximate \(\eta^2\) coordination, respectively. The Li···\(\eta^6\)-Ph(centroid) distances measure ca. 2.014 Å and 2.049 Å, and the Li···\(\eta^2\)-Ph(C-C midpoint) distances are ca. 2.375 Å and 2.454 Å, respectively. In addition, these outer Li atoms further show
one contact each to lattice benzene molecules (not shown in Fig. 4), the shortest being either a $\eta^1$-$C_6H_6$ contact of ca. 3.052 Å, or a $\eta^2$-$C_6H_6$ contact of ca. 3.410 Å to the C-C midpoint. The product is a tetrameric PhN(Li)-N(Li)Ph aggregate from the formal addition of zero-valent lithium to azobenzene.

**Fig. 4** Molecular structure of compound 7 (30% probability thermal ellipsoids). Hydrogen atoms and solvent molecules have been omitted for clarity. Selected bond lengths (Å) and angles (°): N(1)-N(2) 1.466(2), N(3)-N(4) 1.469(2), N(1)-Li(1) 1.992(4), N(1)-Li(2) 2.023(4), N(2)-Li(3) 2.018(4), N(2)-Li(3’) 2.052(4), Li(2)-N(3’) 2.022(4), Li(2)-N(3) 2.048(3), N(3)-Li(2’) 2.022(4), Li(3)-N(4) 1.998(4), Li(3)-N(2’) 2.052(4), N(4)-Li(4) 1.984(4); N(2)-N(1)-Li(1) 92.47(14), N(2)-N(1)-Li(2) 100.11(14), N(1)-N(2)-Li(3) 105.54(14), Li(1)-Li(2)-N(1) 101.06(15), N(1)-N(2)-Li(3’) 124.16(14), Li(3)-Li(2)-Li(3’) 74.24(15); Symmetry transformation: ‘1 -x,y,-z+1/2.

In order to obtain compound 7 for additional spectroscopic data, we attempted a synthesis from an excess of lithium metal and azobenzene. A slurry of an excess of lithium metal in benzene was treated with azobenzene at room temperature and within minutes to one hour, the red-orange colour from azobenzene faded to a more yellow reaction mixture. After several hours of stirring, the mixture was filtered and concentration of the yellow solution afforded crystalline $[\{\text{PhN(Li)-N(Li)Ph}_4\}]_7$·6$C_6H_6$ in low to moderate isolated yield. The identity of the crystalline material was
confirmed by a unit cell determination using synchrotron radiation and compared to the previously obtained crystals using 1. Once crystallised, which likely happens during the reduction reaction, the yellow compound is only sparingly soluble in hot benzene. \(^1\)H and \(^{13}\)C\{\(^1\)H\} NMR spectra of this compound as a yellow solution/slurry recorded at elevated temperature in deuterated benzene are not very informative and only display weak and very broad resonances characteristic for aromatic groups. The addition of some THF led to dissolution, but is accompanied with a colour change to yellow-green brown and further only shows very broad and overlapping \(^1\)H, \(^7\)Li\{\(^1\)H\} and \(^{13}\)C\{\(^1\)H\} NMR resonances in the respective spectra.

The reactivity of the LiH units from 1 and metallic Li, respectively, towards azobenzene is summarized in scheme 2 in a simplified form. Hydrolithiation of soluble LiH across the N=N double bond of azobenzene is expected to furnish a monolithiated hydrazine derivative with newly formed protic hydrogen with umpolung of its charge. From the s-block of the periodic table, there is precedent for this reactivity in form of a stable analogous \(\beta\)-diketiminate magnesium fragment [LMg\(^+\) \(\leftrightarrow\) Li\(^+\)] formed via the comparable hydromagnesiation reaction.\(^{17}\) This intermediate was not observed in the Li case and likely rapidly reacts with further LiH units under hydrogen evolution, as observed by \(^1\)H NMR spectroscopy, and forms the isolated dilithium hydrazine-1,2-diide product 7. This represents a complete and facile low temperature hydrogen generation from lithium hydride without protic reagents. Alternatively, the hydrazine-1,2-diide product 7 was prepared by direct reduction of azobenzene with two equivalents of lithium metal. Similarly, a \(\beta\)-diketiminate stabilized dimeric magnesium(I) compound adds the magnesium fragments across the N=N double bond of azobenzene, [LMg\(\leftrightarrow\) Li\(\cdot\)], though the Mg\(^{2+}\) coordination to the resulting hydrazine-1,2-diide ligand involves some dearomatization of the phenyl rings and it thus acts as a bis-azaallyl ligand, and shows a shorter N–N single bond (1.424(2) Å).\(^{17}\)

![Scheme 2 azobenzene reaction with LiH fragments and Li metal](image)

The stabilizing phosphinoamide ligand \([\text{Ph}_2\text{PNDip}]^-, \text{L}^-\) in 1 and 2 was found to react with several of the investigated substrates, and addition products with dimethylsilicone (3) and azobenzene (5) units have been structurally characterized. The different reactivity is shown in Scheme 3. The
phosphinoamide reaction with the dimethylsilicone units proceeds with an N-attack on the Si centre and forms a silanolate with a neutral donating amidophosphine (P^{III}) centre (a). In contrast, the phosphinoamide addition onto azobenzene proceeds with P-attack to yield a chelating hydrazido ligand with a \( \sigma^4 \lambda^5 \) phosphorane (P^{V}) centre plus neutral donating imino nitrogen centre (b). The first reaction is an addition reaction without formal change of redox states and the latter involves a redox reaction between the P centre and azobenzene-N\(_2\) core.

Scheme 3 silicone and azobenzene addition onto a lithium phosphinoamide

This difference in reactivity can be explained with the ‘hard and soft (Lewis) acid and base concept’. The hard amide nitrogen atom attacks the hard silicone Si^{IV} centre (scheme 4 (a)) and the softer phosphine attacks the softer electrophile azobenzene (b). Although a likely explanation, steric reasons for this difference cannot completely be excluded. Structural data on phosphinoamide complexes strongly favour a formulation with the negative charge located on the more electronegative N atom,\(^8,18\) see chart 2 A, and not on the P atom, chart 2 B. Previously it has been pointed out that phosphinoamides (such as in form A) rather react as iminophosphides (as in B) towards electrophiles such as MeI or Ph\(_2\)PCl and P-substituted products are formed.\(^8,18\) These electrophiles can be regarded as relatively soft and are thus attacked by the softer nucleophilic site of the anion.

Chart 2 phosphinoamide and iminophosphide mesomeric forms of \( \text{L}^- \)
Conclusions

The LiH moieties in the hydrocarbon-soluble LiH complex 1 can undergo hydrolithiation reactions with some heteroatom-containing unsaturated organic substrates, such as benzophenone, dicyclohexylcarbodiimide (DCC) and azobenzene. For DCC, fragments with the expected lithium formamidinate have been found while for azobenzene, a hydrolithiation leads to an umpolung reaction yielding a protic NH that reacts with a further LiH to produce H₂. This represents a facile low temperature hydrogen liberation from LiH fragments without the use of protic reagents (though a protic species is formed as an intermediate) or high temperature. No reactions of 1 with 1,1-diphenylethylene, diphenylacetylene, and 1,1-diphenylfulvene, respectively, have been observed at room temperature. The hydrometalation reactivity is comparable to that of related s-block β-diketiminate stabilized CaH²,¹⁹ and MgH²,¹⁷,²⁰ fragments, though the latter examples appear both more reactive and thermally robust; the former observation is likely due to the capacity of the divalent metal ions to better activate the substrate and likely not due to differences in ionic character of the hydride moieties.

It has furthermore been found that several of the investigated reactions of 1 in here were accompanied by reactions of the stabilizing phosphinoamide ligand with the respective substrates. The phosphinoamide [Ph₂PNDip] was found to react with azobenzene via attack of the P atom, and with a dimethylsilicone moiety from silicone grease via attack of the N atom. This differing reactivity can be explained by the hard and soft acid base approach, though steric reasons can’t be excluded. The phosphinoamide moiety can consequently not be considered an inert spectator ligand for these reactivity studies and the introduction and development of more inert stabilizing ligands is required to further advance the chemistry of group 1 metal hydride complexes. To this end, the recent introduction of large pyrazolato-stabilised LiH clusters¹⁰ can be a suitable approach to suppress these types of side-reactions.

Experimental section

General considerations

All manipulations were carried out using standard Schlenk and glove box techniques under an atmosphere of high purity dinitrogen. Benzene, toluene, tetrahydrofurane and hexane were dried and distilled over molten potassium. ¹H, ⁷Li{¹H}, ¹³C{¹H}, and ³¹P{¹H} NMR spectra were recorded on a Bruker DPX 300 or Bruker Avance 400 spectrometer in deuterated benzene and were referenced to the residual ¹H or ¹³C{¹H} resonances of the solvent used, or external aqueous LiCl,
or H$_3$PO$_4$ solutions, respectively. IR spectra were recorded using a Perkin Elmer RXI FT-IR spectrometer as Nujol mulls between NaCl plates, or on solids protected with a thin layer of nujol using an Agilent Cary 630 ATR FTIR spectrometer. The solid state mass spectrum was recorded using an Agilent 5975C inert MSD with triple-axis detector and SIS direct insertion probe. Melting points were determined in sealed glass capillaries under dinitrogen and are uncorrected. Elemental analyses were performed by the Elemental Analysis Service at London Metropolitan University. [(LLi)$_4$(LiH)$_4$] 1, and [LLi] $^2$ were prepared according to literature procedures. All other reagents were used as received (Aldrich chemical company). Abbreviations: br = broad, vbr = very broad, m = multiplet. NMR scale reactions were typically carried out on ca. 20 mg samples in 5 mm NMR tubes with J.Young stopcock in dried deuterated benzene (ca. 0.55 mL), followed by $^1$H and $^{31}$P{$^1$H} NMR spectroscopy, and are described in the main text. $^1$H and $^{31}$P{$^1$H} NMR spectra of reactions of [(LLi)$_4$(LiH)$_4$] 1, and [LLi] 2, with DCC and PhN=NPh, respectively, are given in the electronic supplementary information (ESI).

Spectroscopic data for [LLi(THF)$_3$]

The title compound was obtained by recrystallization of a [LLi] containing sample from THF. The spectroscopic data is similar to that previously reported for [LLi(THF)$_2$]. Yellow crystals; mp: 97-100°C; $^1$H NMR (C$_6$D$_6$, 400.1 MHz, 303 K): δ 1.22 (m, 12H, THF-OCH$_2$CH$_2$), 1.31 (d, $J_{CH}$ = 6.8 Hz, 12H, CH(CH$_3$_)$_2$), 3.18 (m, 12H, THF-OC$_2$H$_2$CH$_2$), 4.16 (sept, br, $J_{CH}$ ≈ 6.8 Hz, 2H, C$_3$H$_2$(CH$_3$_)$_2$), 6.95-7.29 (m, 9H, Ar-H), 7.75-7.85 (m, 4H, Ar-H); $^7$Li NMR (C$_6$D$_6$, 155.5 MHz, 303 K): δ 0.77 (s); $^{13}$C{$^1$H} NMR (C$_6$D$_6$, 100.6 MHz, 303 K): δ 24.4-24.5 (CH(C$_3$)$_2$), 28.0 (d, $J_{CP}$ = 4.8 Hz, CH(CH$_3$_)$_2$), 68.2 (THF-OCH$_2$CH$_2$), 118.7 (d, not well resolved, Ar-C), 123.5 (d, $J_{CP}$ = 1.7 Hz, Ar-C), 126.6 (Ar-C), 127.9 (d, $J_{CP}$ = 4.5 Hz, Ar-C), 131.6 (d, $J_{CP}$ = 18.8 Hz, Ar-C), 144.6 (d, $J_{CP}$ = 5.4 Hz, Ar-C), 152.9 (d, br, $J_{CP}$ ≈ 30 Hz, Ar-C), 156.2 (d, $J_{CP}$ ≈ 19 Hz, Ar-C); $^{31}$P{$^1$H} NMR (C$_6$D$_6$, 162.0, 303 K): δ 60.5 (br); IR (nujol), ν~cm$^{-1}$: 1583m, 1460s, 1432m, 1417m, 1375m, 1366m, 1307s, 1253m, 1231s, 1185s, 1102m, 1075m, 1045s, 911s, 822m, 778s, 737s, 699s, 680m, 574m.

[(LSiMe$_2$OLi)$_2$(HDCCLi)$_2$] 3·3 C$_6$H$_6$ and [(HDCC)$_9$Li$_8$O] $^4$ $^3$ 3

The reaction of [(LLi)$_4$(LiH)$_4$] 1 with DCC at room temperature led to oily product mixtures that couldn’t be separated. $^1$H and $^{31}$P{$^1$H} NMR spectra for the in-situ reaction can be found in the ESI (Fig S1 and S2) plus those of the related reaction of [LLi] 2 with DCC (Fig S3-5). Separation attempts did lead to small amounts of crystals of the title compounds that were structurally
characterised only after incorporation of silicone grease (3) or traces of air or moisture (4); further details are described in the main text.

\[ [(\text{LN(Ph)N(Ph)Li})_2] \ 5 \]

The title compound was formed and isolated from reactions involving \([\text{LLi}_4(\text{LiH})_4] \ \text{1, and [LLi]} \ \text{2 with azobenzene, respectively, see main text. For a preparative scale: Azobenzene (0.245 g, 1.346 mmol, 1.03 eq) was added to a cooled (-80°C) fine slurry of [LLi] \ 2 (0.48 g, 1.306 mmol) in toluene (20 mL). The reaction was stirred briefly at this temperature, then slowly warmed to room temperature and stirred overnight. An off-white crystalline precipitate of 5 had formed which was filtered off. Concentration of the yellow-brown filtrate to \(\text{ca. 10 mL and cooling to 4°C afforded a second crop of colourless crystals of 5, further concentration to ca. 4 mL and cooling to 4°C afforded a small third crop. Obtained crops were washed with a small amount of } n\text{-hexane (ca. 3-4 mL) and dried under vacuum. Yield: 0.42 g (0.382 mmol, 58%); mp: decomposition, above ca. 210°C gradually more yellow, then brown; fully decomposed at around 240°C; } ^1\text{H NMR (C}_6\text{D}_6, \ 300.1 \text{ MHz, 303 K): } \delta 0.25 \text{ (vbr, 12H, CH(C}_3\text{H}_3)_2 \text{), 0.90 (vbr, 12H, CH(CH}_3)_2 \text{), 3.47 (br, 4H, CH(CH}_3)_2 \text{), 6.47-7.33 (m, 38H, Ar-H), 7.67-7.83 (br, 8H, Ar-H); } ^1\text{H NMR (C}_6\text{D}_6, \ 300.1 \text{ MHz, 333 K): } \delta 0.70 (\text{br, 24H, CH(CH}_3)_2 \text{), 3.44 (sept, } J_{\text{H-H}} \approx 6.8 \text{ Hz, 4H, CH(CH}_3)_2 \text{), 6.54 (t, br, } J_{\text{H-H}} \approx 7.2 \text{ Hz, 4H, Ar-H), 6.72 (t, vbr, 4H, Ar-H), 6.82-7.31 (m, 30H, Ar-H), 7.74 (dd, br, } J_{\text{H-H}} \approx 10.8, 7.8 \text{ Hz, 8H, Ar-H); } ^7\text{Li NMR (C}_6\text{D}_6, \ 155.5 \text{ MHz, 303 K): } \delta 3.3 \text{ (br); } ^{13}\text{C\{^1\text{H}} \text{ NMR (C}_6\text{D}_6, \ 75.5 \text{ MHz, 333 K): } \delta 24.4 \text{ (vbr, CH(CH}_3 \text{)), 28.5 (CH(CH}_3)_2 \text{), 112.8 (br, Ar-C), 114.9 (Ar-C), 119.8 (d, not well resolved, Ar-C), 121.3 (Ar-C), 122.8 (d, } J_{\text{C-P}} = 3.5 \text{ Hz, Ar-C), 123.9 (d, } J_{\text{C-P}} = 2.4 \text{ Hz, Ar-C), 128.3 (Ar-C), 128.7 (Ar-C), 130.0 (Ar-C), 131.3 (br, Ar-C), 133.0 (m, br, overlapping Ar-C), 141.3 (Ar-C), 145.3 (d, } J_{\text{C-P}} = 6.3 \text{ Hz, Ar-C), 147.2 (d, } J_{\text{C-P}} = 19.2 \text{ Hz, Ar-C), 160.9 (Ar-C); } ^3\text{P\{^1\text{H}} \text{ NMR (C}_6\text{D}_6, \ 162.0, \ 303 K): } \delta 19.7 \text{ (vbr, 22.5 (vbr), } ^{31}\text{P\{^1\text{H}} \text{ NMR (C}_6\text{D}_6, \ 121.5, \ 333 K): } \delta 21.0 \text{ (br); IR (nujol), } \nu_{\text{~cm}^{-1}}: 1594, 1479, 1460, 1437, 1376, 1332, 1298, 1280, 1228, 1214, 1111, 1052, 1027, 944, 812, 778, 750, 721, 690; \text{ elemental analysis (%) for C}_72\text{H}_74\text{Li}_2\text{N}_6\text{P}_2: calcd: C 78.67, H 6.79, N 7.65; found: C 78.63, H 6.68, N 7.55.}

\text{Spectroscopic data for } [(\text{LN(Ph)N(Ph)Li(THF)})] \ 6 \text{ Colourless crystals of the title compound were obtained by recrystallizing a sample of 5 from hexane/THF. } ^1\text{H NMR (C}_6\text{D}_6, \ 300.1 \text{ MHz, 303 K): } \delta 0.85 (\text{vbr, 6H, CH(CH}_3)_2 \text{), 1.14 (vbr, 6H, CH(CH}_3)_2 \text{), 1.18 (m, 4H, THF-OCH}_2\text{CH}_2 \text{), 3.36 (m, 4H, THF-OCH}_2\text{CH}_2 \text{), 3.64 (sept, br, 2H, }}}
Yellow, rod to needle-like crystals of the title compound were obtained from the reaction of LiH complex 1 with PhNNPh, alongside [{(Dip)NP(Ph)₂N(Ph)(Ph)Li}₂] 5, see main text.

Route to material for spectroscopic data: Azobenzene (0.23 g, 1.26 mmol) was added to a suspension of finely divided and washed (n-hexane, 2 × 15-20 mL) Li metal (dispersion in mineral oil, high sodium, excess, ca. 60-100 mgs) in benzene (15 mL) at room temperature. Within several minutes, the colour changed from red-orange to largely yellow. The mixture was stirred for six hours and a yellow precipitate had formed alongside residual fine-divided Li. The reaction mixture was brought to 70°C for 30 min to allow more product to dissolve and was filtered at that temperature. Concentration to ca. 6 mL and cooling to 12°C afforded a crop of yellow rod to needle-like crystals of [{PhN(Li)-N(Li)Ph}₄] 7·6 C₆H₆. Inspecting the material under a microscope showed that only one crystal form was present. A determination of the unit cell dimensions on these crystals using synchrotron radiation matched those obtained from the reaction using 1. Two further extractions of the reaction residue with benzene (20 mL) at 70°C afforded yellow solution that, after concentration and cooling, afforded further crops. The yield seems to be largely limited by the low solubility once the product has crystallized, and by separation issues from metallic lithium. The combined solids were dried under vacuum at ca. 40°C to afford [{PhN(Li)-N(Li)Ph}₄] 7·x C₆H₆ (x ≈ 2). NMR spectroscopy suggests that not all six benzene molecules per formula unit were removed upon drying under vacuum. Yield: ca. 70 mgs (ca. 23%); mp: slow colour change towards brown above ca. 240°C, rapid decomposition above ca. 260°C; ¹H NMR (C₆D₆, 300.1 MHz, 338 K): δ ca. 6.12, 6.50, 6.90 (all v br, Ph-H); ¹³C{¹H} NMR (C₆D₆, 75.5 MHz, 338 K): δ ca. 110, 114.2, 128.5 (all br, Ph-C); Addition of a small amount of THF to this sample led to the dissolution of the yellow crystalline material, but also to a colour change to yellow-green brown. ¹H NMR (C₆D₆/THF (ca. 10:1), 300.1 MHz, 300 K): δ ca. 6.36, 6.52, 7.14 (all v br, Ph-H); ⁷Li NMR (C₆D₆/THF (ca. 10:1), 155.5 MHz, 303 K): δ 2.6 (m).
155.5 MHz, 300 K): δ ca. 0.4-1.4 (br m); $^{13}$C{¹H} NMR (C₆D₆/THF (ca. 10:1), 100.6 MHz, 300 K): δ ca. 108, 114, 130 (all v br, Ph-C); IR (nujol), ν~cm⁻¹: 1569s, 1543m, 1533m, 1464s, 1320m, 1286s, 1256s, 1164m, 1151m, 1070m, 1017m, 974m, 835m, 864m, 835m, 813m, 775m, 759s, 742s, 688s; El-MS (solid state, 70eV) m/z (%): 182.1 (27, PhN₂⁺), 105.0 (13, PhN⁺), 93 (21, PhNH₂⁺), 77.0 (100, Ph⁺).

X-ray crystallography

Suitable crystals were mounted in silicone oil and were either measured using an Oxford Xcalibur Gemini Ultra diffractometer (6) with MoKα radiation (λ = 0.71073 Å), or at the MX1 beamline at the Australian Synchrotron using synchrotron radiation with a wavelength close to MoKα radiation. All structures were refined using SHELX.²¹ All non-hydrogen atoms were refined anisotropically. Semi-empirical (multi-scan) absorption corrections were performed on all datasets. In the structure of [LLi(THF)₃] (see the electronic supplementary information), one coordinated THF molecule (O2) was disordered and successfully modelled with two positions (ca. 65% and 35% parts) for C29-C32. The three benzene molecules in [(LSiMe₂OLi)₂(HDCCLi)₂] 3·3C₆H₆ were poorly ordered and have been refined using geometry restraints. The Dip group on N1 shows a relatively large libration mode that lead to some Level B alerts in cif-check. The relatively low data completeness of 95.7% (at 25.00° theta) for [{(LN(Ph)N(Ph)Li)}₂] 5 is due to the experimental setup at the synchrotron at time of collection and only one phi scan was collected. Refinement details are summarized in Table 1 and further information can be found in the crystallographic information files. CCDC 948283-948287 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.
