This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Identification of BP16 as a non-toxic cell-penetrating peptide with highly efficient drug delivery properties†

DOI: 10.1039/b000000x

Antimicrobial peptides are an interesting source of non-cytotoxic drug delivery vectors. Herein, we report on the identification of a new cell-penetrating peptide (KKLFKKILKLL-NH₂, BP16) from a set of antimicrobial peptides selected from a library of cecropin-melittin hybrids (CECMEL11) previously designed to be used in plant protection. This set of peptides was screened for their cytotoxicity against breast adenocarcinoma MCF-7, pancreas adenocarcinoma CAPAN-1 and mouse embryonic fibroblasts 3T3 cell lines. BP16 resulted to be non-toxic against both malignant and non-malignant cells at concentrations up to 200 μM. We demonstrated by flow cytometry and confocal microscopy that BP16 is mainly internalized in the cells through a clathrin dependent endocytosis and that efficiently accumulates in the cell cytoplasm. We confirmed that the cell-penetrating properties of BP16 are retained after conjugating it to the breast tumor homing peptide CREKA. Furthermore, we assessed the potential of BP16 as drug delivery vector by conjugating the anticancer drug chlorambucil to BP16 and to a CREKA-BP16 conjugate. The efficacy of the drug increased between 6 and 9 times when conjugated to BP16 and between 2 and 4.5 times when attached to the CREKA-BP16 derivative. The low toxicity and the excellent cell-penetrating properties clearly suggest that BP16 is a suitable vector for the delivery of therapeutic agents into cells.

Introduction

The efficacy of anticancer treatments remains as a key challenge in medicine. Current therapies are hindered by the appearance of toxic side effects and the development of multi-drug resistance by cancer cells. 1,2 Moreover, the use of therapeutic agents is limited by their low permeability through biological membranes. Therefore, there is an actual interest in developing new approaches to cancer treatment. 3 A promising strategy in this area is the use of cell-penetrating peptides (CPPs) as drug delivery systems. 4-9 CPPs are usually short cationic sequences and may be derived from long peptides or proteins present in nature (i.e., Tat peptide or penetratin) or be de novo designed peptides (i.e., transportan, polyarginine peptides, β-peptides, peptoids, oligocarbamates or polyproline helices). 9-12 The mechanism of action of CPPs initially involves their binding to the negatively charged head groups of lipids or proteins in the plasma membrane which is then followed by their internalization. The exact mode of internalization is still poorly understood but it has been shown to depend on several factors such as the structure and concentration of the CPP as well as the cargo to be transported and the specific cell line. 7,8,12-14 It is believed that endocytosis is the major mode of uptake for CPPs, however direct translocation can also occur. Due to their ability to cross biomembranes in a non-disruptive way, CPPs offer an opportunity to increase bioavailability of drugs, enhancing their activity, and reducing their dosage. In this sense, CPPs have been described as efficient carriers of nucleic acids, proteins, small molecule drugs and imaging agents. 4-6 Focusing on the idea of obtaining new CPPs with very low toxicity, cationic antimicrobial peptides (AMPs) have emerged as good candidates 12,19,22 Like CPPs, AMPs are short sequences, containing between 9 and 30 amino acids, and most of them are cationic and amphiphatic. These peptides show a broad spectrum of activity against bacteria, fungi, enveloped viruses, parasites, and tumor cells, while exhibiting low eukaryotic cytotoxicity. 24-31 Several AMPs are being studied for the treatment of human diseases, and some of them have already entered pre-clinical and clinical trials. 26,27 The mechanism of action of AMPs also includes their electrostatic interaction with the negatively charged phospholipid membranes causing morphological changes such as pore formation or cell lysis, however their translocation into the cytoplasm is not uncommon. 32-35 Due to the latter property, the use of AMPs as CPPs is a field of interest to develop non-cytotoxic delivery vectors. In fact, AMPs, such as LL-37, SynB, melittin and bLFcin6, are able to translocate across human plasma membranes and to act as drug transporters. 36-39 Binding of a CPP to a low-molecular weight drug results in an improved uptake, which is associated with a decrease of the dose required to achieve a significant therapeutic effect. 1 In particular, several efforts have been made to conjugate the cytotoxic agent
chlorambucil (CLB) to CPPs in order to improve its efficacy.\textsuperscript{40-43} Chlorambucil (CLB) is a well-known nitrogen mustard typically used to treat leukemia, but also some breast, lung and ovarian cancers. It is believed that CLB is taken up by passive diffusion and alkylates DNA bringing about its cross-linking.\textsuperscript{44} Although this nitrogen mustard is highly effective against certain cancers, its use is limited by the lack of selectivity and the low permeability through cell membranes. To overcome these limitations, CLB has been conjugated to CPPs such as pVEC or sC18.\textsuperscript{40,41,43}

Despite the high efficiency of CPPs in mediating cellular uptake of pharmacologically active molecules, their use for targeted therapy is limited by their low level of selectivity. Several approaches aimed at improving the specificity of CPPs towards tumor cells have been developed.\textsuperscript{45} One of these strategies relies on the conjugation of a CPP with a homing peptide. These peptides bind selectively to overexpressed receptors in human tumor cells providing a means of targeting CPPs towards desired cells or tissues.\textsuperscript{46-49} However, most homing peptides have no internalization properties and only can deliver cargos to the cell surface. Thus, homing peptide-CPP conjugates may act as efficient vectors for drug delivery into a specific cell target, improving drug bioavailability, and decreasing side effects and toxicity in healthy cells. An example of homing peptide is CREKA (Cys-Arg-Glu-Lys-Ala) which was identified by in vivo screening of phage-displayed peptide libraries in breast tumors of MMTV-PyMT transgenic mice. CREKA specifically homes to tumors by binding to fibrin and fibrin-associated clotted plasma proteins present in the vessels and the interstitial stroma of tumors.\textsuperscript{47,50-52} Since CREKA is not able to internalize cancer cells, it is a good candidate to design peptide-mediated systems for targeted cell delivery of drugs.\textsuperscript{41,42}

This study is focused on the search for new CPP candidates and was based on a library of linear undecapeptides (CECMEL11) previously described by Badosa and co-workers to be used for plant protection.\textsuperscript{53} This library included sequences highly active against phytopathogenic bacteria and fungi, and low haemolytic activity. Similarly to CPPs, these peptides are cationic and are able to adopt an amphipathic structure. In fact, one member of this library, BP100, has been described as an efficient CPP in plant tobacco cells.\textsuperscript{54} This background prompted us to study the suitability of peptides from the CECMEL11 library as drug delivery vectors in cancer cells. We first selected several members of this library displaying different antimicrobial and hemolytic activity profiles. Some analogues containing arginine residues were also synthesized and included in the study. The cytotoxicity of these peptides was evaluated in cancer and healthy cell lines. The cellular uptake properties of the peptide with the optimal cytotoxic profile as CPP were then evaluated. We also examined the potential of this CPP candidate as drug carrier by conjugating it to CLB. In addition, this candidate was conjugated to the homing peptide CREKA to obtain a selective delivery

vector for CLB in cancer cells and to confirm that the cell penetrating properties were retained after the incorporation of CREKA and CLB. Thus, we evaluated the cytotoxicity of the CLB-CREKA-CPP conjugate against cancer and healthy cells and its cellular uptake properties.

Results and discussion

Peptide design and synthesis

AMPs represent a source of CPPs because both families share similar structural characteristics. With the aim of identifying new CPPs, we focused our attention on a 125-member library of AMPs (CECMEL11) previously described by Badosa and co-workers.53 The general structure of this library is R-X'KLKILLKX11-L-H2, where X' and X11 correspond to amino acids with various degrees of hydrophobicity and hydrophilicity (Leu, Lys, Phe, Trp, Tyr, Val) and R includes different N-terminal derivatizations (H, Ac, Ts, Bz, Bn). Thus, peptides of this library are highly cationic and their amphipathic character becomes evident when they are represented by means of an Edmunson wheel plot. These structural features have been described as crucial for their antimicrobial activity and also may confer on them cell-penetrating properties.32-33 In fact, BP100, a member of the CECMEL11 library, has been reported as an efficient agent to transport cargoes into plant cells.54

In the present study, we examined the ability of subsets of this CECMEL11 library to internalize cancer cells and to transport a drug. Two sets of peptides were considered: (i) undecapeptides BP16, BP76, BP81, BP100 and BP105, and the Arg-containing peptides BP307 and BP308; and (ii) peptide conjugates containing in their structure: the undecapeptide BP16 and the DNA alkylating agent CLB (BP325), BP16 and the homing peptide CREKA (BP327), and BP16, CLB and CREKA (BP329). To analyze the cellular internalization, BP16, BP325, BP327, and BP329 were labeled with 5(6)-carboxyfluorescein (CF).

The five peptides of the first set (BP16, BP76, BP81, BP100 and BP105) (Table 1) were selected based on their distinct antibacterial activity against the plant pathogens Erwinia amylovora, Pseudomonas syringae and Xanthomonas vesicatoria, and their different hemolysis percentage at 150 μM.52 BP100 and BP76 are highly active against these phytopathogens (MIC of 2.5 to 7.5 μM) and low hemolytic (22-34%), BP81 is highly active (MIC of < 2.5 to 5 μM) and moderately hemolytic (65%), BP105 is highly active (MIC of 2.5 to 7.5 μM) and highly hemolytic (91%), and BP16 is poorly active (MIC > 7.5 μM) and non-hemolytic (0%).

The Arg-containing peptides BP307 and BP308 were derived from BP100 and BP16, respectively (Table 1). They were included in this study because most common CPPs, such as Tat or penetratin, are Arg-rich peptides.53 This residue has been shown to play a key role in peptide internalization due to the hydrogen-bond formation of the guanidino moiety with phosphates, sulfates and carboxylates on cellular components. BP307 and BP308 were tested for their antibacterial activity against the above pathogens and for their hemolysis. The replacement of Lys for Arg in BP16 and BP100 significantly influenced the antibacterial activity. While BP307 resulted to be less active (MIC of 6.2 to 12.5 μM) than BP100, BP308 displayed higher antibacterial activity (MIC of 3.1 to 12.5 μM) than BP16. In contrast, the hemolysis was not affected and BP307 and BP308 exhibited similar hemolytic activity (28% and 1%, respectively) than the corresponding parent peptide.

Peptide conjugates included in the second set were designed based on BP16 (Table 1), which showed the best profile as drug delivery vector among all the above tested undecapeptides (see below). Peptide BP325 was prepared by coupling CLB to the N-terminus of BP16 via an amide bond. The use of CLB is hampered by its low stability in aqueous environments and its low permeability through biomembranes, limitations that have been overcome by its conjugation to a CPP.41,44 Moreover, since the use of homing peptides has been described to increase the cell-type specificity of CPPs. BP327 was designed by conjugating the homing peptide CREKA to the N-terminus of BP16. CREKA was selected for its excellent targeting ability to breast tumors and because its linear structure avoids the additional cyclization step required for most other homing peptides. In addition, with the aim of improving the specificity of the cytotoxic agent CLB, BP329 was synthesized by attaching CLB to CREKA-BP16. Control peptides CREKA and CLB-CREKA were also prepared (Table 1).

These peptides were manually synthesized on an FMoc-Rink-MBHA resin or on an aminomethyl ChemMatrix resin following a standard Fmoc/Bu strategy and were obtained as C-terminal

*The IC50 values were determined by the MTT assay after 48 h of peptide exposure. Data represents the mean ± SD of at least three independent experiments made in triplicates. Percent hemolysis at 150 μM. The confidence interval for the mean is included.
amides. Couplings of the conveniently protected Fmoc-amino acids and of CLB were mediated by ethyl 2-cyano-2-(hydroxyimino)acetate (Oxyma) and N,N'-diisopropylcarbodiimide (DIPCDI) in N,N-dimethylformamide (DMF) or N-methyl-2-pyrrolidinone (NMP), depending on the length of the sequence. Peptides were cleaved from the resin by acidolytic treatment and were obtained in excellent purities (87-100%, Table 1), as determined by analytical HPLC. Their identity was confirmed by ESI-MS and HRMS.

On the other hand, BP16 and BP327 (CREKA-BP16) were labeled with 5(6)-carboxyfluorescein by coupling this fluorescent label to their N-terminus leading to CF-BP16 and BP328, respectively (Table 1). 5(6)-Carboxyfluorescein labeled CREKA was also prepared (CF-CREKA). Moreover, BP325 (CLB-BP16) and BP329 (CREKA-BP16), incorporating CLB at the N-terminus, were labeled at the side-chain of Lys9 of the BP16 fragment, affording BP326 and BP330, respectively. 5(6)-Carboxyfluorescein was introduced using DIPCDI and Oxyma, followed by piperidine washes before cleavage of the peptide from the resin. These washes served to remove overincorporated carboxyfluorescein moieties. For the synthesis of peptides BP326 (CLB-BP16(CF)) and BP330 (CLB-CREKA-BP16(CF)), the lysine residue to be labeled was incorporated as Fmoc-Lys(Dde)-OH. The N-1-[4-(4,4-dimethyl-2,6-dioxycyclohex-1-ylidene)ethyl] (Dde) group was selectively removed by treatment with hydrazine prior to the coupling of the fluorescent label. Acidolytic cleavage afforded the labeled peptides in excellent purities (81-97%), and they were characterized by ESI-MS and HRMS.

**Cell cytotoxicity of the CPP candidates**

A good CPP to be used as a delivery vector of an anticancer drug must display no toxicity against cancer as well as healthy cells. Hence, the cytotoxicity of undecapeptides BP16, BP76, BP81, BP100, BP105, BP307 and BP308 was screened in breast adenocarcinoma MCF-7 and pancreas adenocarcinoma CAPAN-1 cell lines. The IC50 was determined by the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay after 48 h of peptide exposure. As shown in Table 2, except for BP100, the undecapeptides were more active against CAPAN-1 than against MCF-7 cells. The cytotoxic activity of BP76 and BP105 was significant against these two cell lines, displaying IC50 values of 23.5 and 22.7 µM against CAPAN-1, respectively, and of 26.3 and 29.2 µM against MCF-7 cells, respectively. BP81, BP100 and its Arg-containing analogue BP307 were considerably active against one cell line with IC50 values ranging from 24.2 to 35.7 µM. BP16 and BP308 were the least cytotoxic undecapeptides. BP308 showed an IC50 of 148.2 and 97.0 µM against CAPAN-1 and MCF-7 cells, respectively, and BP16 displayed no cytotoxic effects against any of the cancer cell lines tested (IC50 > 200 µM).

These results indicate that these undecapeptides exhibit lower cytotoxicity against cancer cells in comparison with their antibacterial activity. However, the structural features that govern the anticancer activity of the CECMEL11 library sequences, BP16, BP76, BP81, BP100 and BP105, correlate with the general trend for the antibacterial activity of this library. Thus, peptides with a net charge of +5 or +6 displayed high cytotoxic activity, whereas BP16 that has a net charge of +7 was inactive.

Moreover, BP16, BP76, and BP100 that only differ in the amino acid at position 10 displayed a very distinct cytotoxic activity. The same effect was observed for BP307 and BP308. This result confirms previous data on how subtle changes in a peptide sequence influence the biological activity. On the other hand, the replacement of Lys with Arg in BP16 and BP100 caused a different effect in the cytotoxicity. While this replacement...
preferentially bind to cancer cell membranes by electrostatic interaction and subsequently enter cells.

The analysis of the activity of undecapeptides on non-malignant mouse embryonic fibroblasts 3T3 revealed that the antiproliferative activity of BP76 and BP81 was high, with IC₅₀ values of 13.5 and 15.5 μM, respectively (Table 2). BP100, BP105, BP307 and BP308 were moderately active (IC₅₀ of 39.0 to 68.0 μM). Notably, BP16 was non-toxic against this cell line exhibiting an IC₅₀ > 200 μM. Furthermore, we also used the hemolysis assay to assess the toxicity of these peptides. As mentioned above, except for BP105 and BP81, undecapeptides displayed low hemolysis at 150 μM (0-34%). Interestingly, BP16 and its Arg analogue BP308 were non-hemolytic even at 375 μM (data not shown). Even though these undecapeptides did not show selectivity between the malignant and non-malignant cell lines tested, some sequences (BP76, BP100, and BP307) did not show significant hemolytic activity at concentrations much higher than the IC₅₀ values against the cancer cell lines tested.

Moreover, the stability in fetal bovine serum of BP16 was also evaluated and compared to that of Tat₅₂. After exposure to 10% serum at different time intervals, the presence of peptide was analyzed by HPLC. Results showed that both peptides exhibited similar stability, with 70% degradation after 45 min of incubation.

Taken together, these results allowed the identification of BP16, a short and highly cationic peptide with a suitable activity profile to be considered as an excellent CPP candidate. In particular, in contrast to most common CPPs that exhibited cytotoxicity even at low concentrations, BP16 was non-toxic to both malignant and non-malignant cell lines at concentrations up to 200 μM and, therefore, was selected for further studies.

Cellular uptake of BP16

To characterize the capacity of internalization of BP16 into cancer and non-malignant cells, MCF-7 and 3T3 cells were incubated at 37 °C with 5(6)-carboxyfluorescein labeled BP16 (CF-BP16) at different concentrations (0, 5, 25 and 50 μM) for different times (1, 3 and 6 h) (Figure 1). The mean fluorescence of the cells, corresponding to the peptide uptake, was quantified by flow cytometry. Cells were harvested by trypsinization, which also prevented non-specific plasma membrane binding of the peptide. As represented in Figure 1, CF-BP16 was efficiently internalized by the cells in a time and concentration-dependent manner. The mean fluorescence of the cells increased over time with parallel internalization kinetics in both cell lines. The cellular uptake of CF-BP16 was intense during the first 3 h of incubation, particularly when the cells were treated with the peptide at 25 and 50 μM. After treatment with 50 μM CF-BP16, the mean fluorescence of 3T3 cells increased from 5 ± 2 (0 h) to 1829 ± 335 (1 h), 4895 ± 464 (3 h) and 6953 ± 536 (6 h), while the mean fluorescence of MCF-7 cells rose from 4 ± 1 (0 h) to 1431 ± 307 (1 h), 3997 ± 720 (3 h) and 5830 ± 410 (6 h). These results point out that the internalization of CF-BP16 is more elevated in the non-malignant 3T3 cells than in MCF-7 cells, indicating the lack of selectivity of BP16 for cancer cells.

A good correlation between peptide concentration and its uptake by the cells was observed, especially when they were treated with 5 and 25 μM CF-BP16. At the different incubation times, the mean fluorescence of MCF-7 cells were lower than in MCF-7 cells. This finding is consistent with the observed selectivity of BP16 for cancer cells.
when CF-BP16 concentration was increased from 5 to 25 µM, the mean cellular fluorescence increased by 5 to 6-fold in 3T3 cells and by 8 to 13-fold in MCF-7 cells. In contrast, slight differences in the mean cellular fluorescence (less than 1.7-fold increase) were determined when both cell lines were incubated with CF-BP16 at 25 or 50 µM, revealing a saturation of the peptide uptake by the cells at concentrations higher than 25 µM.

We compared the capacity of internalization of BP16 with that of the well-known CPP Tat[40]. With this aim, MCF-7 cells were incubated at 37 °C with CF-BP16 and CF-Tat[49] at 25 µM for 1, 3 and 6 h (Figure 2). Interestingly, CF-BP16 and CF-Tat[49] showed the same mean fluorescence intensity values indicating that BP16 exhibits an excellent cellular uptake.

To gain more insight into the internalization and intracellular distribution of BP16, the cellular uptake of CF-BP16 was further analyzed by confocal microscopy. For this purpose, MCF-7 cells were incubated with 25 µM CF-BP16 at 4 °C for 30 min and at 37 °C for 10, 30, 60, 120 and 180 min (Figure 3A). No fluorescence was observed after 30 min of incubation at 4 °C. However, when the cells were treated at 37 °C, a very faint punctate fluorescent staining was observed inside the cells after 10 min, revealing an incipient cellular uptake of the peptide. The number of fluorescent particles gradually increased over time and, after 180 min of incubation, there was a prominent fluorescent staining inside the cells, demonstrating an intense internalization of the peptide during this period of time. Higher magnification (1000x) images from cells exposed to CF-BP16 for 180 min (Figure 3B) revealed that the fluorescent particle were located throughout the whole cytoplasm, with a significant clustering at the periphery of the cell nucleus. An optical sectioning indicated that no fluorescence particles were placed inside the cell nucleus (Figure 3C). In addition, to find out whether CF-BP16 cellular entry was dependent on specific interaction with the plasma membrane, MCF-7 cells were pre-incubated with 25 µM CF-BP16 at 4 °C for 30 min and, after extensive washing with saline phosphate buffer, were incubated at 37 °C for 25 min. CF-BP16 internalization was also compared with the Alexa647-conjugated transferrin (TF-A647) which is a well-known model of receptor dependent internalized ligands. Confocal images revealed that while transferrin-A647 labelled endocytic structures inside the cell as expected, no intracellular CF-BP16 was observed (Figure 3D). This result may indicate the possibility that CF-BP16 is weakly membrane associated and removed after washes or that CF-BP16 could be receptor independent and preferentially fluid phase internalized.

These findings highlight a plausible mechanism for the internalization of BP16. The mechanism of CPP uptake is controversial and still under debate. Two main pathways have been suggested: endocytosis and direct translocation across the membrane bilayer. These cell uptake phenomena can be related to the hydrophobicity of the CPP. Translocation has been associated with hydrophobic peptides while hydrophilic and amphipathic sequences can be internalized by both mechanisms. In addition, the endocytosis process is energy-dependent and is assumed to be inhibited by peptide incubation at low temperature. Altogether, the results observed for the incubation of CF-BP16 in MCF-7 cells at 4 and 37 °C suggest that the endocytic pathway may play a major role in BP16 internalization.

Figure 4. CF-BP16 is dynamin dependent internalized and follows the endocytic degradation pathway. (A) MCF-7 cells were pre-incubated for 15 min at 37 °C with or without 100 µM dynasore and then CF-BP16 (25 µM) and Alexa647-labelled transferrin (TF-A647, 60 µg/ml) were added and further incubated for 60 min. Confocal images were acquired through the Alexa647 (red) and CF (green) channels. (B) MCF-7 cells expressing RFP-Lamp1 (red) were incubated with CF-BP16 (green) and TF-A647 (blue) for 60 min at 37 °C. Insets show magnified images and arrows indicate CF-BP16/RFP-Lamp1 positive vesicles. (bars are 10 µm).

To further characterize the BP16 endocytosis, the role of dynamin, which is involved in vesicle scission from plasma membrane, was analysed by means of dynamin inhibition using the specific inhibitor dynasore (Figure 4). The BP16 endocytosis was also compared with the transferrin protein as a specific marker of a dynamin dependent endocytosis. MCF-7 cells were pre-incubated with 100 µM of dynasore for 15 minutes at 37 °C and then CF-BP16 and TF-A647 were added and further incubated for 60 minutes. Confocal microscopy images showed an accumulation of TF-A647 and CF-BP16 in the same structures at the plasma membrane after dynasore treatment, likely unscissored clathrin coated pits (CCPs) (Figure 4A). On the other hand, in control cells, CF-BP16 and TF-A647 were found mostly in different endocytic structures inside the cell (Figure 4A). Indeed, high degree of co-localization between CF-BP16 and the ectopically expressed RFP-Lamp1, a marker of late endosomes and lysosomes, was clearly detected (Figure 4B). These results suggest that CCPs, are an important port of entry for BP16. However, BP16 and transferrin follow different endocytic pathways inside the cell, a known recycling pathway for transferrin and a degradation route for BP16.

Next, in order to ascertain the importance of clathrin dependent endocytosis (CDE), the role of this dynamin dependent pathway in CF-BP16 uptake was examined in cells...

Cell cytotoxicity of peptide conjugates

The potential use of BP16 as vector for the delivery of the DNA alkylating agent CLB was assessed by exposing MCF-7, CAPAN-1 and 3T3 cells to CLB and the CLB-BP16 conjugate (BP325). The IC₅₀ was determined by the MTT assay after 48 h of peptide exposure. As shown in Table 3, CLB alone exhibited low cytotoxicity against the three cell lines (IC₅₀ of 73.7 to 152.5 µM). In contrast, BP325 displayed high activity, with IC₅₀ values of 12.0, 13.7 and 20.6 µM against MCF-7, CAPAN-1 and 3T3 cells, respectively. Thus, the conjugation of CLB to BP16 increased the cell cytotoxicity of this nitrogen mustard by 6-fold in MCF-7 cells, by 7-fold in 3T3 cells and by 9-fold in CAPAN-1 cells. Since BP16 is non-toxic at these concentrations (IC₅₀ > 200 µM), this toxicity must be attributed to the CLB moiety. This increase of activity clearly demonstrates that BP16 contributes to the internalization of CLB through the cell membrane, enhancing its efficacy. Therefore, in agreement with earlier reports, the mechanism of action of the CLB-BP16 conjugate seems to be much more efficient than the passive diffusion mechanism suggested for CLB alone.

Homing peptides are employed to enhance the selectivity of CPPs towards malignant cells. Thus, we next investigated whether the cell-penetrating properties of BP16 were retained after conjugation with the breast tumor homing peptide CREKA and also if this homing peptide-CPP conjugate could provide selective internalization of CLB into cancer cells. With this aim, the cytotoxicity of the conjugate CLB-CREKA-BP16 (BP329) was evaluated in MCF-7, CAPAN-1 and 3T3 cells, CREKA, CLB-CREKA and the conjugate CREKA-BP16 (BP327) were also assayed for comparison purposes. CREKA and CLB-CREKA were non-toxic (IC₅₀ > 200 µM) and BP327 displayed low cytotoxicity (IC₅₀ of 74.5 to 76.2 µM). In contrast, the conjugate CLB-CREKA-BP16 (BP329) was significantly active, with IC₅₀ values ranging from 33.0 to 35.2 µM. These results showed that the incorporation of CREKA decreased the activity of the CLB-BP16 conjugate BP325, however they confirmed that BP16 was able to internalize both CREKA and CLB since the cytotoxicity of BP329 (CLB-CREKA-BP16) increased 2- to 4-fold the one of CLB alone. Furthermore, the lack of selectivity observed for BP329 could be attributed to the fact that CREKA was originally identified by in vivo phage display and recognized fibrin-associated clotted plasma proteins in the tumor stroma. On this basis, the behavior of CREKA in vitro could differ to the one previously described in vivo. However, these results show that BP329 displayed a higher activity than CLB alone proving the validity of BP16 as CPP for cell delivery of therapeutically useful molecules.

The IC_{50} values were determined by the MTT assay after 48 h of peptide exposure. Data represents the mean ± SD of at least three independent experiments made in triplicates.

Cellular uptake of CLB peptide conjugates

In order to determine if the differences in the cytotoxic activity of the CLB peptide conjugates BP325 (CLB-BP16) and BP329 (CLB-CREKA-BP16) were related to their internalization properties, these conjugates were labeled with 5(6)-carboxyfluorescein (CF) affording BP326 and BP330, respectively, and analyzed by flow cytometry. In addition, the homing peptide CREKA and the CREKA-BP16 conjugate (BP327) were also labeled (CF-CREKA and BP328, respectively) and included in the study.

The cellular uptake of CF-CREKA and BP328 at 25 μM was determined by flow cytometry after 3 h of incubation in 3T3 and MCF-7 cells at 37 °C. As represented in Figure 6, very low intracellular fluorescence levels were detected in both cell lines when treated with CF-CREKA, indicating that CREKA alone was unable to internalize into the cells. These results are in accordance with previous studies describing that CREKA displays no cell-penetrating capacity in cultured breast cancer cells. When comparing the fluorescence of CF-BP16 and BP328 (CF-CREKA-BP16), it was observed that the cell-penetrating properties of BP16 were significantly reduced when conjugated to the homing peptide, probably because the coupling of CREKA restricts the interaction of BP16 with the cell membrane. Notably, as shown by the intracellular fluorescence levels, BP328 retains significant internalization ability which is required to deliver cytotoxic agents inside the cells.

The internalization ability of the CLB conjugates BP326 (CLB-BP16(CF)) and BP330 (CLB-CREKA-BP16(CF)) at 25 μM was evaluated by flow cytometry in MCF-7 cells after 3 h of incubation at 37 °C. To our surprise, while the fluorescence of BP326 (4272 ± 453) was not significantly different to that of CF-BP16 (3035 ± 643), BP330 showed a considerably higher intracellular fluorescence (3966 ± 217) than BP328 (CF-CREKA-BP16) (1789 ± 221). These results are noteworthy since they prove that BP16 is able to efficiently internalize both CLB and CREKA.

These findings also reveal that the incorporation of either CREKA and/or CLB has a strong influence on the cellular uptake of BP16, reflecting that any modification in the molecular structure of this peptide can lead to relevant changes in its cell penetrating properties. In fact, it has been reported that the cargo play an important role in the internalization mechanism of CPPs. Interestingly, despite these modifications, BP16 remains as an efficient drug delivery vector.

Conclusions

In the present study, we have identified BP16 as a new CPP with high cellular uptake in vitro. In contrast to other CPPs previously reported, BP16 displays no cytotoxicity against malignant and non-malignant cells and, moreover, shows no hemolytic activity. We have demonstrated that BP16 exhibits high efficient penetration through endocytic mechanisms, accumulating in the cell cytoplasm at short time periods. In addition, the conjugation of the DNA alkylating agent CLB to BP16 dramatically increases the cytotoxicity of this drug between 6- to 9-fold. We have also shown that, in conjugation with the homing peptide CREKA, BP16 is able to improve the cytotoxic activity of CLB from 2- to 4.5-fold. Taken together, these results confirm that BP16 is an excellent non-toxic delivery vector suitable for the effectively transport of drugs. Further studies on applications of this CPP are underway in our laboratory.

Experimental section

Materials and methods

Unless otherwise stated, common chemicals and solvents (HPLC-grade or reagent-grade quality) were purchased from commercial sources and used without further purification. The 9-fluorenylmethoxycarbonyl (Fmoc) derivatives and Fmoc-Rink-4-methylbenzhydrylamine (MBHA) resin (0.56 mmol/g) were obtained from Senn Chemicals International (Gentilly, France), NovaBiochem (Schwalbach, Germany) or from IRIS Biotech GmbH (Marktredwitz, Germany). Aminomethyl ChemMatrix resin (0.66 mmol/g) was obtained from Matrix Innovation Inc (St-Hubert, Canada). Ethyl 2-cyano-2-(hydroxymino)acetate (Oxyna) was purchased from Novabiochem (Nottingham, UK). Trifluoroacetic acid (TFA), triisopropylsilane (TIS), dimethyl sulfoxide (DMSO), D,L-dithiothreitol (DTT), N,N’-disopropylcarbodiimide (DIPCDDI), chlorambucil (CLB), 5(6)-carboxyfluorescein (CF), fluorescein isothiocyanate dextran mol wt 10000 (FITC-Dextran) and dyes were purchased from Sigma–Aldrich (St. Louis, MO, USA). Transferrin Alexa Fluor® 647 Conjugate was from Molecular Probes (Invitrogen, Life Technologies, Carlsbad, CA). Piperidine was purchased from Fluka (Buchs, Switzerland). N-Methyl-2-pyrrolidinone (NMP), N,N-dimethylformamide (DMF), CH$_3$OH, CH$_2$Cl$_2$, diethyl ether and solvents for high performance liquid chromatography (HPLC) were obtained from Scharlau (Sentmenat, Spain).
Peptide synthesis

General method for solid-phase peptide synthesis

Peptides from Table 1, Tat49 and CF-Tat49 were synthesized manually by the solid-phase method using Fmoc-type chemistry and the following side-chain protecting groups: tert-butylxycarbonyl (Boc) for Lys, tBu for Tyr and Glu, triyl (Tr) for Cys, and 2,2,5,7,8-pentamethylichroman-6-sulphonyl (Pmc) for Arg. A Fmoc-Rink-MBHA resin (0.56 mmol/g) or an aminomethyl ChemMatrix resin (0.66 mmol/g) were used as solid support to obtain peptide amides. Coupling of Fmoc-Rink (4 equiv) onto the aminomethyl ChemMatrix resin was mediated by DIPCDI (4 equiv) and Oxyma (4 equiv) in DMF at room temperature overnight. Couplings of the Fmoc-aminoacids (4 equiv) were performed using DIPCDI (4 equiv) and Oxyma (4 equiv) in DMF under stirring at room temperature for 2 h, and monitored by the Kaiser test.93 For sequences containing up to eleven residues, the Fmoc group was removed by treating the resin with a mixture of piperidine/DMF (3:7, 1 × 2 min + 1 × 10 min). For longer sequences, Fmoc group removal was carried out with piperidine/DMF (3:7, 1 × 3 min + 3 × 10 min). After each coupling and deprotection step, the resin was washed with DMF (6 × 1 min), and CH3Cl (6 × 1 min), and air-dried. After the coupling of the eleventh residue, NMP was used instead of DMF. Peptide elongation was performed by repeated cycles of Fmoc group removal, coupling and washings.

Once the synthesis was completed, peptidyl resins were subjected to N-terminal Fmoc group removal. Then, peptides were cleaved or the peptidyl resins were derivatized with CLB and/or with 5(6)-carboxyfluorescein. Cleavage of peptides from the resin was performed by treatment with TFA/TIS/H2O (95:2.5:2.5) for 3 h at room temperature. Peptides containing a cysteine residue were cleaved with TFA/TIS/H2O/DTT (92.5:2.5:2.5:2.5) for 3 h at room temperature. Both procedures were followed by TFA evaporation by bubbling N2 into the solution. Crude peptides were precipitated by adding cold diethyl ether (-20 °C) and collected by centrifugation. This procedure was repeated twice. Finally, peptides were dissolved in H2O/CH3CN (50:50 v/v containing 0.1% TFA), lyophilized and tested for purity by HPLC. Analysis was carried out with a Kromasil 18 C18 reverse-phase column (4.6 x 40 mm; 3.5 μm particle size) with a 2-100 % B linear gradient over 7 min at a flow rate of 1.0 mL/min. Solvent A was 0.1% aqueous TFA and solvent B was 0.1 % TFA in CH3CN. Detection was performed at 220 nm. ESI-MS and HRMS (ESI) were used to confirm peptide identity. Peptides from Table 1, Tat49 and CF-Tat49 were obtained in purities ranging from 81 to 100% (Table 1).

Synthesis of CLB-peptide conjugates

Derivatization with CLB was performed by treating the corresponding peptidyl resin with CLB (5 equiv), DIPCDI (5 equiv) and Oxyma (5 equiv) in DMF or NMP under stirring at room temperature for 5 h. The completion of the reaction was checked by the Kaiser test.94 The resin was then washed with NMP (6 × 1 min), CH3OH (6 × 1 min), and CH3Cl (6 × 1 min), and air dried.
Synthesis of N-terminal 5(6)-carboxyfluorescein-labeled peptides

For the N-terminal derivatization with 5(6)-carboxyfluorescein, this fluorophore (2.5 equiv) was first pre-activated with Oxyma (2.5 equiv) and DIPCDI (2.5 equiv) in CH₂Cl₂/NMP (1.9) for 10 min. The mixture was added to the corresponding N-terminal deprotected peptidyl resin and reacted overnight at room temperature protected from light by covering it with aluminum foil due to the light sensitivity of the 5(6)-carboxyfluorescein.

Completeness of the coupling was confirmed using the Kaiser test. The resin was then washed with NMP (1 × 5 min), piperidine/NMP (1:5, 1 × 15 min), NMP (6 × 1 min), CH₂Cl₂ (6 × 1 min), CH₃OH (6 × 1 min), and CH₂Cl₂ (6 × 1 min) and air dried.

Synthesis of 5(6)-carboxyfluorescein-labeled CLB-peptide conjugates

These conjugates were prepared from a peptidyl resin incorporating the lysine residue to be labeled protected with N-[4-(4-dimethyl-2,6-dioxycyclohex-1-ylidene)ethyl] (Dde) at the N°-amino group. After CLB coupling, the Dde group was removed by treatment with hydrazine/NMP (2.98, 5 × 20 min) under stirring at room temperature and the deprotection progress was monitored by the Kaiser test. Then, the resin was washed with NMP (6 × 1 min) and CH₂Cl₂ (6 × 1 min) and air dried.

Next, fluorophore labeling with 5(6)-carboxyfluorescein was carried out as described for the N-terminal carboxyfluorescein labeled peptides.

Cytotoxicity assays

Cytotoxicity of peptides BP16, BP76, BP81, BP100, BP105, BP307, BP308, CREKA and BP327, CLB-peptide conjugates CLB-CREKA, BP325 and BP329, and CLB in 3T3, MCF-7, and CAPAN-1 cells was determined by the MTT assay. Peptides and CLB-peptide conjugates were dissolved in Milli-Q water to obtain 2 mM stock solutions. CLB was dissolved in DMSO to provide a 75 mM stock solution.

Appropriate aliquots of these solutions were diluted in the cell culture medium to obtain the final working concentrations. Aliquots of 4000 3T3 cells, 6000 MCF-7 cells or 10,000 CAPAN-1 cells were seeded on 96-well plates 24 h prior to the treatments. Then, cells were treated for 48 h with the corresponding compound at concentrations ranging from 0 to 200 µM. After removal of the treatment, cells were washed with PBS and incubated for additional 2 h in the darkness with fresh culture medium (100 µL) with MTT (10 µL). The medium was discarded and DMSO (100 µL) was added to each well to dissolve the purple formazan crystals. Plates were agitated at room temperature for 10 min and the absorbance of each well was determined with an absorbance microplate reader (ELx800, BioTek, Winooski, USA) at a wavelength of 570 nm. Three replicates for each compound were used, and all treatments were tested at least in three independent experiments. For each treatment, the cell viability was determined as a percentage of the control untreated cells, by dividing the mean absorbance of each treatment by the mean absorbance of the untreated cells. The concentration that reduces by 50% the cell viability (IC₅₀) was established for each compound.

Hemolysis

The data corresponding to the hemolytic activity of peptides was previously reported by Badosa et al. It was evaluated at 150 µM by determining the hemoglobin release from erythrocyte suspensions of fresh human blood (5% v/v) using absorbance at 540 nm.

Stability of BP16 and Tat₄₉ in serum

The stability of BP16 and Tat₄₉ was evaluated in fetal bovine serum. Each peptide (1 mg) was exposed to 10% aqueous filtered fetal bovine serum (2 mL) at 37 ºC. After 5, 10, 15, 30 and 45 min exposure, aliquots (200 µL) were removed and proteins were precipitated with acetonitrile (200 µL). Samples were cooled to 0 ºC for 15 min and centrifuged (11,000 rpm, 5 min). The supernatant was analyzed by HPLC. The digestion was estimated as the percentage of degraded peptide calculated from the decrease of the HPLC peak area of the native peptide.

Flow cytometry

The uptake efficiency of CF-BP16, CF-CREKA, and BP328 by 3T3 and MCF-7 cells, and of CF-Tat₄₉, BP326, and BP330 by MCF-7 cells was quantified by flow cytometry. Aliquots of 50,000 cells were seeded in 24-well plates and allowed to attach for 24 h. Next, cells were incubated with CF-BP16 at 5, 25 and 50 µM for 1, 3 and 6 h, with CF-CREKA, BP328, BP326 and BP330 at 25 µM for 3 h or with CF-BP16 and CF-Tat₄₉ at 25 µM for 1, 3 and 6 h at 37 ºC. The cells were harvested by trypsinization and gently washed with 2% FBS in cold PBS. The fluorescence of the cells, corresponding to the cellular uptake of the carboxyfluorescein labeled peptides, was analyzed using a FACS Calibur (Becton Dickinson Immunocytometry Systems, San Jose, CA) equipped with the CellQuest™ software (Becton Dickinson). The mean fluorescence intensity was represented on a four orders of magnitude log scale (1–10,000). The effect of Cherry-DPF expression on CF-BP16, CF-Tat₄₉, transferrin-A647 and FITC-Dextran uptake in MCF-7 cells was also analysed by flow cytometry. MCF-7 cells seeded in 6 well-plates were transfected with Cherry-DPF plasmid using Effectene (Qiagen, Hilden, Germany) according to the manufacturer’s specifications. To generate the Cherry-DPF plasmid, the DPF fragment (aa: 501-874) from human Eps15 was obtained by polymerase chain reaction, cloned into pEGFP-C1 vector (Clontech) using Xhol and PstI restriction sites and after that GFP was replaced with the mCherry fluorescent protein. After 24 h of protein expression, cells were incubated with transferrin-A647 (60 µg/ml) combined with CF-BP16 (25 µM), CF-Tat₄₉ (25 µM) or FITC-Dextran (2 mg/ml) for 60 min at 37 ºC and washed two times with cold PBS. The remaining fluorescence at the cell surface was removed by a 3 min cold acid wash (sodium acetate 0.2 M, sodium chloride 0.5 M, pH 4.5) and the intracellular fluorescence was quantified using a LSRFortessa (Becton Dickinson) equipped with the CellQuest™ software (Becton Dickinson). Ten thousand cells were analyzed in each experiment.
Confocal microscopy

MCF-7 cells grown on coverslips and incubated with the different fluorescent-labeled molecules were washed with cold PBS and fixed with freshly prepared 4% paraformaldehyde in PBS for 15 min at 4°C. After washing twice with PBS, the coverslips were mounted in Mowiol (Calbiochem, Merck, KGaA, Darmstadt, Germany) or using a fluorescence mounting medium (Dako, Carpinteria, CA, USA). The images were acquired using a Leica TCS SP5 laser scanning confocal microscope (Leica Microsystems Heidelberg GmbH) equipped with DMi6000 inverted microscope, blue diode (405 nm), argon (458/476/488/514), diode pumped solid state (561 nm) and HeNe (633) lasers. Final imaging was performed using ImageJ software.

Statistical analysis

The statistical analysis was performed with the SPSS statistical software for Windows (version 15.0; SPSS Inc., Chicago, IL, USA). Quantitative variables were expressed as mean and standard deviation (SD). The normality of the data was tested using the Shapiro-Wilk test. The differences between data with normal distribution and homogeneous variances were analyzed using the parametric Student’s t test. A value of \(p<0.05\) was considered significant.

BP16 is a non-toxic cell-penetrating peptide with high cellular uptake in vitro. This peptide is an efficient vector for the delivery of therapeutic agents into cells, as it has been shown for the anticancer drug chlorambucil.
