IspG and IspH are proteins that are involved in isoprenoid biosynthesis in most bacteria as well as in malaria parasites and are important drug targets. They contain cubane-type 4Fe-4S clusters that are involved in unusual 2H⁺/2e⁻ reductions. Here, we report the results of electron paramagnetic resonance 10 spectroscopic investigations of the binding of amino- and thiolo-HMBPP (HMBPP=E-1-hydroxy-2methyl-but-2-enyl 4-diphosphate) IspH substrate-analog inhibitors to both proteins, as well as the binding of HMBPP and an acetylene diphosphate inhibitor, to IspG. The results show that amino-HMBPP binds to reduced IspH by Fe-C π -bonding with the olefinic carbons interacting with the unique 4^{th} Fe in the 4Fe-4S cluster, quite different to the direct Fe-N ligation seen with the oxidized protein. No such π -complex is 15 observed when amino-HMBPP binds to reduced IspG. No EPR signal is observed with IspH in the presence of dithionite and thiolo-HMBPP, suggesting that the 4Fe-4S cluster is not reduced, consistent with the presence of a 420 nm feature in the absorption spectrum (characteristic of an oxidized cluster). However, with IspG, the EPR spectrum in the presence of dithionite and thiolo-HMBPP is very similar to that seen with HMBPP. The binding of HMBPP to IspG was studied using hyperfine sublevel correlation ₂₀ spectroscopy with ¹⁷O and ¹³C labeled samples: the results rule out direct Fe-O bonding and indicate π bonding. Finally, the binding to IspG of a potent acetylene diphosphate inhibitor was studied by using electron-nuclear double resonance spectroscopy with ¹³C labeled ligands: the large hyperfine couplings indicate strong Fe-C π -bonding with the acetylenic group. These results illustrate a remarkable diversity in binding behavior for HMBPP-analog inhibitors, opening up new routes to inhibitor design of interest in 25 the context of anti-bacterial and anti-malarial drug discovery, as well as "cubane-type" metallobiochemistry, in general.

Introduction

There is currently great interest in the structure, function and inhibition of the enzymes involved in the 2-C-methylerythritol 4-30 phosphate (MEP) or 'non-mevalonate' isoprenoid biosynthesis pathway. This pathway is present in most bacteria as well as in the protozoan parasite, Plasmodium falciparum, the causative agent of the most common and serious form of malaria.^{2,3} This pathway is not used by humans and is essential for survival and 35 is, therefore, an important drug target. In addition, the MEP pathway is present in plants, making inhibitors of interest as potential herbicides. The last two steps in the pathway are $2H^{+}/2e^{-}$ reductions carried out by 4Fe-4S cluster-containing proteins (Scheme 1) in which there are unique 4th iron atoms in the cluster 40 that are not coordinated to protein Cys residues. The penultimate protein in the pathway is IspG, 2-C-methyl-D-erythritol-2,4cyclo-diphosphate (1) reductase (also known as GcpE), which catalyzes the reduction of 1 to E-1-hydroxy-2-methyl-but-2-enyl 4-diphosphate (HMBPP; 2). The last enzyme in the pathway is 45 IspH, HMBPP reductase (also known as LytB) and catalyzes the

reduction of HMBPP to isopentenyl diphosphate (IPP, 3) and dimethylallyl diphosphate (DMAPP, 4), in a ~ 5:1 ratio. The structures of both the bacterial IspG and IspH proteins are known. 4-7 IspG contains two domains: a TIM barrel (A) involved 50 in binding the diphosphate group of 1 as well as in providing H⁺, and a 4Fe-4S cluster containing domain (B), involved in reduction, and in recent work the structure of 1 bound to a bacterial IspG has been reported.8 The bacterial proteins function as "head-to-tail" dimers with the TIM (triose phosphate 55 isomerase) barrel of one partner in the dimer associated with the 4Fe-4S cluster-containing domain of the other molecule in the dimer.⁶⁻⁸ In plant and malaria parasite IspGs, there is also a third domain (A*), located between the A and B domains. The A* domain has essentially no sequence conservation between 60 different organisms, but has been proposed to again adopt a TIM (triosephosphate isomerase) barrel fold and act in a primarily structural capacity, enabling the A and B domains in a monomer to come together and function catalytically. IspH is also modular and contains three αβ domains, the 4Fe-4S cluster being buried at 65 the center of the trimeric structure. 4,5

In previous work we reported that two classes of molecules,

acetylenes and pyridines, 10-13 acted as modest IspH inhibitors, binding at or close to the 4th Fe of the 4Fe-4S cluster, with the acetylenes also inhibiting IspG^{9,11} with IC₅₀ values as low as 0.77 μM. More recently, the amine analog of 2, 7 as well as the thiol s analog 8 have been reported¹⁴ to be even more potent IspH inhibitors (IC₅₀ $\sim 0.2 \mu M$) and it was shown via Mössbauer spectroscopy and quantum chemical calculations that both bound to the oxidized ([Fe₄S₄]²⁺) form of IspH, forming Fe-N and Fe-S bonds, respectively, with the 4th Fe. Here, we report that IspG is 10 likewise inhibited by these compounds. We also present the results of EPR¹⁵ and HYSCORE (hyperfine sublevel correlation spectroscopy^{16,17}) investigations into the nature of the inhibition of both IspH as well as IspG by 7 and 8, in the presence of sodium dithionite; and ENDOR (electron nuclear double 15 resonance 16,18) spectroscopic examination of the inhibition of IspG by 5 using two selectively ¹³C-labeled species, and of the binding of 2 to IspG, using uniformly as well as three specifically ¹³C-labeled ligands.

Scheme 1. IspG- and IspH-catalyzed reactions and their inhibitors.

Results and discussion

Binding of amine and thiol inhibitors to IspH.

We first investigated the question of how 7 and 8 might bind to the reduced form of IspH, since they are known to bind via N or 25 S to the oxidized ([Fe₄S₄]²⁺) protein. Is this also the case with reduced IspH? To do this, we used EPR and HYSCORE spectroscopy. We began by investigating binding of the amine ligand 7 to Aquifex aeolicus IspH (AaIspH), Plasmodium falciparum IspH (PfIspH), and E. coli IspH (EcIspH). The 9.05 30 GHz EPR spectrum (at 10K) of dithionite-reduced AaIspH was reported previously¹⁹ to be a mixture of an $S = \frac{1}{2}$ and $S = \frac{3}{2}$ species, with the $S = \frac{1}{2}$ species having g-values of 2.040, 1.919, 1.849 (Table S1).

The $g \sim 2$ region in the absence of any added ligand is shown 35 for reference in Figure 1A. The spectrum is similar to that found with other 4Fe-4S proteins, such as aconitase. ²⁰ On addition of **7**, a sharp new feature appears (having $g_i = 2.134, 2.006, 1.973,$ Table S1). With PfIspH and EcIspH, there is only very weak signal intensity in the absence of added ligands, but in both cases 40 in the presence of 7 intense and sharp signals with $g_i \sim 2.137$, 2.007, 1.980, Table S1, are seen (Figure 1C,D) suggesting that the ligand binds at or close to the $[Fe_4S_4]^+$ cluster in all three IspHs. The question then arises as to how 7 binds. There are two main possibilities: First, 7 binds via its NH2 group to the [Fe₄S₄]⁺ 45 cluster in basically the same manner as that proposed for binding to the oxidized cluster, i.e. by forming a Fe-N bond to the 4th Fe. 14 Second, 7 might bind to IspH with its aminomethyl group "rotated-out", away from the cluster, interacting with E126, as proposed earlier¹¹ for the CH₂OH group in the HMBPP substrate, 50 as now seen crystallographically²¹ with HMBPP, and

confirmed by ¹⁷O-HYSCORE spectroscopy. ²²

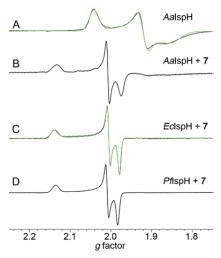

Figure 1. 9.05 GHz CW-EPR spectra of IspHs. (A) 1.3 mM AaIspH 55 (reduced) + 20 eq dithionite. (B) 1 mM AaIspH + 40 eq dithionite + 28 eq 7. (C) 1.1 mM EcIspH + 10 eq 7 + 30 eq DT. (D) 0.5 mM PfIspH + 20 eq **7** + 80 eq DT. Spectra acquired at 10-24 K.

To help distinguish between these two possibilities, we obtained the HYSCORE spectra of 7 bound to AaIspH, Figure 60 2A, as well as to PfIspH and EcIspH, Figures S1 and S2. To distinguish any 14N hyperfine interaction with the protein backbone from that with the ligand 7, we also obtained the HYSCORE spectrum of 7 bound to ¹⁵N-labeled AaIspH, Figure 2B. If there were a Fe-N bond present in the complex, we would 65 expect a sizeable ¹⁴N hyperfine coupling since there would be a strong metal-ligand orbital overlap facilitating spin density transfer from the metal to the ligand. For example, with the pyridine inhibitor 9 bound to IspH, ¹³ as shown in Figure 2C, the 14 N hyperfine interaction A_{iso} (14 N) is ~ 8 MHz and we previously 70 noted that, on average, A_{iso} (14 N) values were ~ 6 MHz for a series of proteins containing Fe-N bonds. Given that there is no large hyperfine coupling observed (Figure 2A, B), we conclude that there is no direct Fe-N bond in the reduced IspH + 7 complex. In addition, the g_i , g_{iso} and Δg values for IspH + 7 are 75 essentially identical to those we find with HMBPP (2) bound to both E. coli and A. aeolicus IspH mutants (Table S1, shown graphically in Figure 3), supporting similar binding of both 2 and 7. Plus, the spectrum of the pyridine inhibitor 9 bound to IspH is very broad, quite different to the sharp spectrum found with 7. 80 We thus propose that 7 binds to IspH in basically the same manner as does HMBPP (2), and a model based on the "rotatedout" HMBPP X-ray structure²¹ in which the HMBPP ligand's OH group is replaced by an NH₃⁺ group is shown in Figure 2D. As can be seen in this (HMBPP X-ray based) structural model, the 85 ligand's CH₂NH₃⁺ group can interact with the E126 carboxylate, providing strong Coulombic interactions that may help account for its potent IspH inhibition (where assays are carried out under reducing conditions).

As we reported previously²², there are three major clusters in ₉₀ this (Figure 3) and related $\Delta g/g_{iso}$ plots²²: classic [4Fe-4S]⁺ clusters where $g_{iso} < g_e$, from proteins such as ferredoxins, aconitase, and ligand-free IspH/IspG; oxidized HiPIPs and synthetic $[4\text{Fe}-4\text{S}]^{3+}$ models with $g_{iso} > g_e$ and $[4\text{Fe}-4\text{S}]^+$ clusters

with alkene or alkyne ligands where $g_{iso} > g_e$ but where the g_{iso} values are generally smaller than those of typical HiPIPs. Clearly, the amine inhibitor 7 falls in the "ligand free" region discussed earlier, that is, the nitrogen does not bind directly to Fe.

Figure 2. HYSCORE spectra of IspH with nitrogen-containing inhibitors, and a model for the AaIspH + **7** complex. (A) AaIspH + **7**. T = 15 K, v = 10 9.706 GHz, magnetic field = 3455 G, sum spectrum of $\tau = 136$, 168, 200 and 256 ns. (B) ¹⁵N-labeled AaIspH + **7**. T = 15 K, v = 9.712 GHz, magnetic field = 3460 G, sum spectrum of $\tau = 136$, 168, 200 and 256 ns.

(C) AaIspH + **9** (adapted from Wang et al. ¹²). T = 8 K, v = 9.66 GHz, magnetic field = 3600 G, $\tau = 136$ ns. (D) Model for binding of **7** is (protonated, ammonium form) based on the X-ray structure of IspH + **2** (PDB ID 3KE8 and 3SZU, Span et al. ²¹)

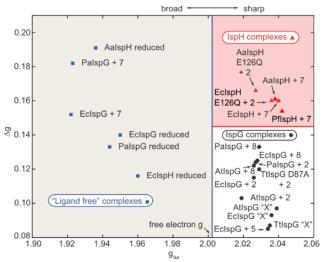

Figure 3. Plot of Δg versus g_{iso} for IspH and IspG. Points to the left are proposed to originate from proteins in the absence of exogenous ligands bound to the cluster and are all broad; points on the right are all from sharp spectra and are proposed to originate from π/σ or HiPIP-like complexes.

Interestingly, there is a small feature centered close to (-1.5, 1.5) MHz in all three AaIspH+7, PfIspH+7 and EcIspH+7 spectra that has not been seen previously with any other ligands. It did not change when ¹⁵N-labeled AaIspH protein was used instead of natural abundance AaIspH (Figure 2B), so it does not arise from a ¹⁴N hyperfine coupling with the protein backbone. The feature can be simulated with a ¹⁴N hyperfine interaction having A_i = ³⁰ [1.85, 1.25, 3.70] MHz, A_{iso} = 2.33 MHz, e^2qQ/h = 0.8 MHz, η = 0.2 (Figure S2). The quadrupole coupling constant is consistent with that expected for an alkyl ammonium²³ group ($e^2qQ/h \sim 0$ – 1 MHz) and the hyperfine coupling anisotropy suggests close proximity to the paramagnetic center, consistent again with the ³⁵ "rotated-out" model proposed above.

We next investigated binding of the thiol ligand **8**, to *Ec*IspH. The IC₅₀ values for **7** and **8** in inhibiting *Ec*IspH are very similar and both bind to the oxidized protein, forming Fe-N and Fe-S bonds, respectively, with the 4th Fe in the cluster. However, the electronic structure of the complex with **8** is spin-delocalized while that with **7** is spin-localized, suggesting that there might be significant differences in electronic structure between **7** and **8** when bound to reduced IspH.

The EPR spectrum of AaIspH in the presence of sodium distribution d

nm, which disappears on dithionite reduction (green trace). The spectrum of oxidized IspH + 8 (red trace) is similar to that of the oxidized protein in the absence of 8; however, addition of dithionite minimally changes the spectrum; the shoulder at ~ 420 5 nm is still seen with IspH + 8 + dithionite. We also find that addition of 8 to dithionite-reduced IspH generates the 420 nm shoulder (superimposed on the large dithionite background peak), suggesting that reduced IspH+8 is relatively unstable, consistent with the lack of any EPR signal for this system, Figure S3A.

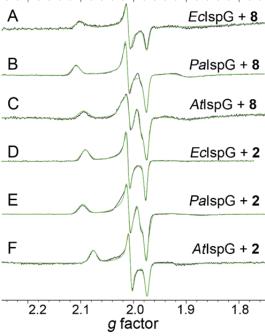

Figure 4. 9.05 GHz CW-EPR spectra (black) and spectral simulations (green) of E. coli (A, D), P. aeruginosa (B, E), and Arabidopsis thaliana (C, F) IspG in the presence of 8 (A-C) or 2 (D-F). T = 8K, Power = 5 mW. $500-600 \mu M \text{ IspG} + 80 \text{ eq dithionite} + 20-40 \text{ eq 8 or 2}$.

15 Binding of amino, thiol inhibitors and HMBPP to IspG.

We next investigated the inhibition of IspG (GcpE) by 7 and 8. As can be seen in Supporting Information Figure S4, 7 and 8 both inhibit IspG. The IC50 values are in the range 0.8-2.5 μM (Supporting Information Table S2). The EPR spectra of the thiol 20 8 bound to the (two-domain) bacterial IspGs (from E. coli and P. aeruginosa) are shown, together with their spectral simulations and data for the three domain Arabidopsis thaliana IspG, in Figure 4A-C. All three spectra have very similar g_i (Table S1) and hence, g_{iso} (~ 2.03) and Δg (~ 0.13) values (Figure 3), 25 indicating little inter-species variability, as well as no differences between the 2- and 3-domain proteins. Very similar results are found with 2 (HMBPP, containing an OH group) bound to the same proteins, Figure 4D-F, although on average the g_{iso} and Δg values found with 2 are slightly smaller, Table S1. It might be 30 assumed that both 2 and 8 would bind to the unique 4th iron in the same way, via Fe-O or Fe-S bonds. However, it is also possible that there are no direct Fe-O or Fe-S bonds arising from these ligands, in reduced IspG. Of course, strong EPR signals are seen with e.g. 4Fe-4S ferredoxins, but there, g-values are rather 35 different, on average g_3 = 1.91, g_{iso} = 1.97 and Δg (= $g_1 - g_3$) ~ 0.15, 22,24 to be compared with the average values of $g_3 \sim 1.98$, g_{iya}

= 2.03 and $\Delta g \sim 0.12$ for 2 and 8 bound to the IspGs, Table S1.

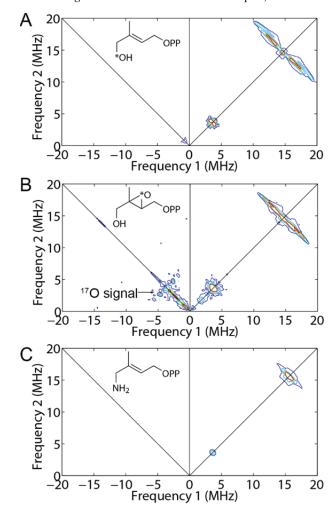

Figure 5. 9.66 GHz HYSCORE spectra of (A) [1-17O]-2 (HMBPP) bound 40 to PaIspG. T = 10 K, magnetic field = 3435 G, $\tau = 136$ ns. (B) HYSCORE of [2,3-¹⁷O]-2 epoxide bound (as the ferraoxetane "X") to TtIspG (adapted from Wang et al. 10). T = 18 K, magnetic field = 3420 G, τ = 136 ns. (C) HYSCORE of 7 bound to PaIspG. T = 8 K, magnetic field = 3660 G, τ = 136 ns.

To investigate HMBPP binding in more detail, we synthesized the $[1-^{17}O]$ analog of 2, labeled at the terminal (1-CH₂OH) group, and obtained a HYSCORE spectrum, Figure 5A. (For more spectra acquired at different field positions and τ values, see Figure S5) There is no evidence for any ¹⁷O HYSCORE signal, 50 suggesting that there is no direct Fe-O bond to the ligand, 2. For purposes of comparison, the HYSCORE spectrum of the ¹⁷Olabeled IspG reactive intermediate "X", shown in Figure 5B, exhibits an intense signal (data from Wang et al. 10), proposed earlier to arise from a ferraoxetane species (i.e. a species 55 containing an Fe-O bond). We thus propose that since we see no evidence for any ¹O hyperfine coupling that 2 (HMBPP) binds to the 4Fe-4S cluster by another mechanism, e.g. π -bonding. This would be similar to the mechanism proposed earlier for the isomer of HMBPP (10) binding to the EcIspH E126Q mutant²² in 60 which the g-values are essentially identical (with $g_1 \sim 2.09$; $g_{iso} \sim$ 2.03, $\Delta g \sim 0.10$) to those seen with 2 bound to EcIspG ($g_1 \sim 2.09$, $g_{iso} = 2.03$, $\Delta g \sim 0.12$, Table S1). The strong similarity in the EPR spectra of 2 and 8 bound to IspG would then suggest that the thiol

ligand binds in a similar manner, consistent with the observation that these spectra are quite unlike those of reduced ferredoxins.²⁴ To investigate the interaction between HMBPP carbon atoms and the IspG [4Fe-4S] cluster, we obtained HYSCORE spectra of [U- 5 13 C], [1- 13 C], [2- 13 C], and [3- 13 C] HMBPPs bound to reduced IspG, Figure 6. There were no large hyperfine couplings observed with the $[U^{-13}C]$ labeled ligand, Figure 6A, unlike the ~17 MHz hyperfine coupling seen for 1 bound to IspG.²⁵ To assign the resonances that were observed we next investigated the three 10 selectively ¹³C-labeled HMBPPs: spectra are shown in Figure 6B-D. The results of spectral simulations (Figures S5-S9) using EasySpin^{26,27} yielded the hyperfine coupling tensors shown in SI Table S3: $[1^{-13}C]$, $A_{ii} = [-0.7, -0.9, 2.2]$ MHz; $[2^{-13}C]$, $A_{ii} = [0.5, -0.9, 2.2]$ 0.7, 4.9] MHz; $[3^{-13}C]$, $A_{ii} = [3.9, -0.3, -0.1]$ MHz. Clearly, all 15 three hyperfine interactions are quite small, although those for the 2 and 3-positions (the double bond) are larger than for C-1, consistent again with a weak π -interaction.

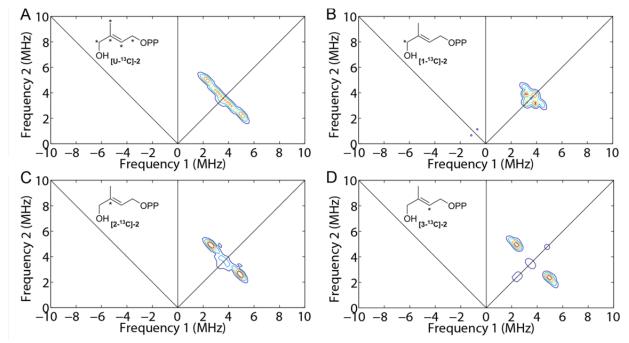

Figure 6. 9.7 GHz HYSCORE spectra of 13 C labeled 2 bound to PaIspG. (A) [U^{-13} C]-2 + PaIspG. Magnetic field = 3315 G, τ = 136 ns. (B) [1^{-13} C]-2 + $_{20}$ PalspG. Magnetic field = 3480 G, τ = 136 ns. (C) [2- $_{13}$ C]-2 + PalspG. Magnetic field = 3435 G, τ = 136 ns. (D) [3- $_{13}$ C]-2 + PalspG. Magnetic field = 3315 G, $\tau = 136$ ns. 1-1.7 mM PaIspG + 40 eq dithionite + 16-20 eq ¹³C labeled **2**. T = 10 K.

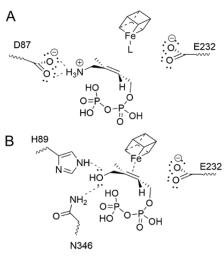

In sharp contrast to the results with 2 and 8, with the amine ligand 7 binding to EcIspG we find a very broad spectrum (Figure S10A) that has similar g_i , g_{iso} and Δg values to those 25 found with the "un-liganded" protein (Figure S10B, Table S1) in which of course OH, H₂O or a protein ligand might be bound to the 4th Fe. We see no evidence for a Fe-N interaction in the HYSCORE spectrum, Figure 5C (also at 3 other fields, Figure S11), plus, we find that the amine ligand 7 displaces HMBPP (2) 30 from PalspG on a tens-of-seconds timescale, as shown in Figure S10C,D. Here, the HMBPP signals (red arrows, Figure S10C) arise from adventitiously bound HMBPP that co-purified with the PaIspG protein.

What is surprising about the results with IspG is how different 35 they are to those found with IspH, given that both proteins have similar 4Fe-4S clusters with unique 4th Fe atoms, and both carry out 2H⁺/2e⁻ reductions. Specifically, with IspH, the amine ligand 7 binds to the reduced protein; the resulting EPR spectrum is very similar to that found with the IspH substrate HMBPP (2) bound 40 to an E126Q mutant; and there is no large ¹⁴N HYSCORE signal - all suggesting π -bonding of a "rotated-out" -CH₂NH₃⁺ species, while with the thiol inhibitor 8, the IspH 4Fe-4S cluster is not reduced, so inhibition is due to binding to oxidized protein. With IspG, the cluster can be reduced in the presence of 2, 7, or 8. The 45 EPR spectra of 2 (HMBPP) and 8 (the thiol ligand) bound to IspG

are very similar to each other, but there is no ¹⁷O hyperfine coupling (or it is very small), suggesting no direct Fe-O bonding (or Fe-S bonding, with 8). Plus, there are only weak interactions between the π -bond in 2 and the cluster, based on the 13 C 50 HYSCORE results. With the amine-ligand 7, the EPR spectrum is similar to that seen with ligand-free protein (and the Δg , g_{iso} values cluster in the "ligand-free region" in Figure 3), and there is no evidence for Fe-N bonding, in which case it seems likely that water or protein ligands (or both) bind to the 4th Fe. These results ss are also supported by the observation that spectra of 2 + PaIspGcan be seen at both 10 and 20 K, Figure S12A, but only at 8 K with 7, Figure S12B. That is, the HMBPP-bound spectrum, as with other HiPIP-like spectra, is sharp and does not broaden at higher temperatures, while the spectrum of 7 bound to IspG is 60 broad and has almost disappeared at 20K, as seen in conventional σ -complexes.

Based on computational docking (with AutoDock Vina²⁸) we find that the ligand NH₂ group can interact (in the NH₃⁺ form) with D87 in IspG, similar to the proposed E126/NH₃⁺ interaction 65 for IspH (based on the X-ray structure of the rotated-out conformer), as illustrated in Figure 7A. To help test this hypothesis we used a D87A Thermus thermophilus IspG mutant. With this mutant there is essentially no EPR signal observed in the absence of any ligand, Figure S13A and only a very weak

signal in the presence of 7, Figure S13). However, in the presence of HMBPP (2) the spectrum (Figure S13C) is essentially the same as that seen with the other, wild-type proteins, suggesting that D87 is involved in binding of the amino-HMBPP (7), but not 5 HMBPP itself. With HMBPP and the thiol ligand 8, we therefore propose that both bind as weak π -complexes to the 4th Fe, as illustrated for 2 in Figure 7B.

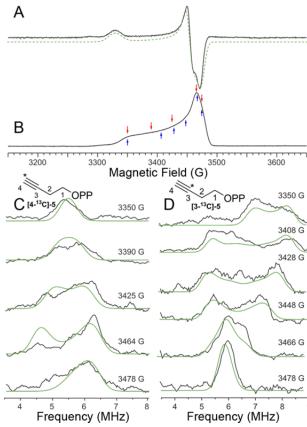

10 Figure 7. Proposed binding of (A) 7 and (B) 2 to IspG (T. thermophilus residue numbering). The nature of L in (A) is unknown.

Binding of acetylene inhibitors to IspG.

Finally, we investigated the EPR and ENDOR spectra of the two specifically ¹³C-labeled acetylene inhibitors, 5. We show the 15 EPR spectra of 5 bound to EcIspG in Figure 8A, B, as well as the Davies ENDOR spectra of [3-13C]-5 and [4-13C]-5 bound to EcIspG, in Figure 8C, D. The g-values found (by spectral simulation) for 5 bound to EcIspG are 2.087, 2.012 and 2.003, leading to $g_{iso} = 2.034$ and $\Delta g = 0.085$, Table S1 and Figure 3. 20 These values are similar to those found with the reactive intermediate "X" bound to both EcIspG as well as T. thermophilus IspG, shown in Table S1 $(g_1 \sim 2.09, g_2 \sim 2.02; g_3 =$ 2.00; $g_{iso} = 2.04$; $\Delta g \sim 0.09$) and Figure 3. In previous work²² we proposed that "X" arose from a $[Fe_4S_4]^{3+}$ $S = \frac{1}{2}$ HiPIP-like 25 cluster and, based on these g-values, extensive charge transfer to the acetylene 5 due to metal-alkyne π interactions seems likely. We also find sizeable ¹³C hyperfine couplings, and from field dependence and spectral simulation results (Figure 8, green) we determined the principal components of the two hyperfine 30 tensors. For [4-13C]-5 (i.e. labeled at the terminal carbon), we obtain $A_{ii} = [5.4 \ 1.5 \ 3.8]$ MHz, and for $[3^{-13}C]$ -5, we find $A_{ii} =$ [4.5 3.0 10] MHz, Figure 8C, D. These tensors indicate close proximity of the acetylene group to the reduced 4Fe-4S cluster, facilitating, we propose, a strong pi interaction. To obtain 35 estimates of the distances involved, we employed the point dipole approximation.²⁹ Using the largest diagonal component of the anisotropic hyperfine tensor together with previously reported spin-projection coefficients for aconitase²⁹ leads to Fe-C₃ distances in the range 2.0-2.6 Å, and Fe-C₄ distances in the range $_{40}$ 2.6-3.2 Å. Since the sum of the Fe and C van der Waals radii is \sim 3.5 Å, 30 these distances are indicative of Fe-C bonding. For HMBPP, the Fe-C2 and Fe-C3 distances are in the range ~2.3-2.9

Å, Table S3, again consistent with a weak pi interaction.

45 Figure 8. 9.7 GHz (A) CW-EPR and (B) swept-spin echo spectrum of EcIspG + 5, T = 15 K. Simulation of spectrum in (A) yields $g_i = [2.003,$ 2.012, 2.087]. Microwave frequency = 9.729 GHz for (A) and 9.758 for (B). Arrows indicate the magnetic fields at which the ENDOR spectra in (C) and (D) were obtained. (C) 9.7 GHz ¹³C Davies ENDOR spectra of 50 EcIspG + [4- 13 C]-5. The principal components of the 13 C hyperfine coupling tensor are A_{ii} (4-13C) = [5.4 1.5 3.8] MHz. Euler angles are α = 32°, $\beta = \gamma = 0$ °. (D) 9.7 GHz ¹³C Davies ENDOR of *Ec*IspG + [3-¹³C]-5. A_{ii} (3-¹³C) = [4.5 3.0 10] MHz and Euler angles are $\alpha = 80^{\circ}$, $\beta = 30^{\circ}$ and γ = 60°. Simulations are in green.

55 Conclusions

In summary: the results we have presented here are of interest for several reasons. First, we find that in addition to inhibiting IspH, both the amine (7) and thiol (8) ligands inhibit IspG, with IC₅₀ values in the 0.8-2.5 uM range. Second, we find that the EPR 60 spectra of 7 bound to IspH as well as 2 or 8 bound to IspG are indicative of π -bonding, with the amino/hydroxyl/thiol groups not directly bonded to Fe. The absence of a large ¹⁴N hyperfine coupling for 7 bound to reduced IspH as well as the absence of a large ¹⁷O hyperfine coupling for [1-¹⁷O]-2 bound to reduced IspG 65 are consistent with these bonding proposals. Third, we find that the g-values for the acetylene inhibitor 5 bound to IspG suggest a π -interaction between Fe and the alkyne group, ^{33,34} and the ¹³C hyperfine tensors for both carbons in the acetylene group of 5 in the complex with IspG also indicate Fe-C bonding. Fourth, the 70 binding of 7 to IspG (see Figure S12) as well as of 8 to IspH did not result in any π -interaction type EPR spectra, and with 8 it appears that the 4Fe-4S cluster in IspH is not reduced by dithionite. These results show, then, an unexpected diversity in spectroscopic behavior – and hence binding modes – for three IspG/IspH inhibitors, results that are of interest in the context of anti-infective drug design targeting isoprenoid biosynthesis. In particular, the possibility of developing leads that inhibit both 5 IspG as well as IspH is likely to be of importance in decreasing resistance, as well as reducing the pro-inflammatory effects of 2 in acute infections³⁵ that would be expected to occur with solely IspH inhibition.

Experimental

10 Chemical Synthesis.

The NH₂- (7) and SH- (8) analogs of HMBPP, as well as [1-¹³C], [2-¹³C], and [3-¹³C]-HMBPP, were from the batches described previously. In addition, in order to investigate bonding of the acetylene 5, we synthesized both [3-¹³C]-5 and [4-¹³C]-5, as described in the Supporting Information, in order to unambiguously determine the hyperfine coupling tensor elements, *A*_{ii}, for each site.

CW-EPR/ENDOR/HYSCORE spectroscopy.

All CW (continuous wave)-EPR experiments were performed on a Varian E-line 122 X-band spectrometer with an Air Products helium cryostat. Typical data acquisition parameters were: microwave frequency = 9.05 GHz; field center = 3250 G; field sweep = 1000 G; modulation frequency = 100 kHz; modulation amplitude = 5 Gauss; time constant = 32 ms; temperature = 8 - 20 k.

Pulsed ENDOR/HYSCORE spectra were obtained on a Bruker ElexSys E-580-10 FT-EPR EPR spectrometer equipped with an Oxford Instruments CF935 cryostat. A Bruker RF amplifier (150 watts, 100 kHz -250 MHz) was used for ENDOR experiments.
30 Davies ENDOR used a three-pulse sequence $\pi_{\rm mw} - t - \pi/2_{\rm mw} - \tau - \pi/2_{\rm mw} = 96$ ns, with $\pi_{\rm RF}$ (10 µs, 3 dB attenuation) applied during t. HYSCORE used a four-pulse sequence $\pi/2_{\rm mw} - \tau - \pi/2_{\rm mw} - t_1 - \pi_{\rm mw} - t_2 - \pi/2_{\rm mw} - {\rm echo}$; $\pi/2_{\rm mw} = 16$ ns and $\pi_{\rm mw} = 32$ ns, 128 points for both t_1 and t_2 , each using 24 ns steps. Time-35 domain data were baseline corrected using a 3rd order polynomial, and then Hamming windowed, followed by zero-filling, and 2D-Fourier transformation and symmetrization. Parameters were typically: microwave frequency = 9.65 - 9.72 GHz, temperature = 8 - 15 K, microwave power attenuation = 6.5 40 - 9 dB.

Acknowledgments

This work was supported by NIH Grant GM065307 (to E. O.). W.W. and J.L. were both supported by predoctoral fellowships from the American Heart Association, Midwest Affiliate (awards 10PRE4430022 to W.W. and 11PRE7500042 to J.L.). We would like to thank Dennis Dean for providing the *isc* protein expression system, Pinghua Liu for providing the *E. coli* IspG expression system, Manuel Rodriguez-Concepción for providing the *A. thaliana* IspG expression system, Hassan Jomaa and Jochen Wiesner for providing the *A. aeolicus* IspH, *P. falciparum* IspH, and *T. thermophilus* IspG expression systems, and Mark J. Nilges for assistance with the EPR spectroscopy.
