22 **Abstract**  
23

24 A kind of natural material, cotton fiber, has been applied as solid-phase extraction  
25 (SPE) adsorbent for sample preparation in the analysis of polycyclic aromatic  
26 hydrocarbons (PAHs) in water samples coupling with high-performance liquid  
27 chromatography (HPLC). The cotton fiber was directly used without any chemical  
28 modifications, which avoided complex synthesis process and large volume organic  
29 solvent consuming. The conditions affecting the extraction efficiency have been  
30 optimized to achieve high detection sensitivity, including elution solvent, ultrasonic  
31 elution time, extraction time, sample volume, salt concentration and organic modifier  
32 addition. Under the optimal conditions, the detection limits for seven PAHs  
33 compounds could reach up to 0.1 - 2.0 ng/L, correspondingly. Furthermore, the  
34 method accuracy was evaluated by recovery measurements in standard spiked  
35 samples and good recoveries of 70.69 – 110.04% with relative standard deviations  
36 (RSDs) less than 10% have been achieved. Consequently, the developed method was  
37 successfully applied for analyzing PAHs in environmental samples: snow water,  
38 metal-fabrication factory wastewater and Xiangjiang River water, with PAHs contents  
39 ranging from 13.2 to 83.1 ng/L, correspondingly. Therefore, the cotton fiber as new  
40 SPE adsorbent showed easy preparation, low cost and great reusability, implying its  
41 promising application for sample preparation.

## 1. Introduction

Polycyclic aromatic hydrocarbons (PAHs) are formed originally during the incomplete combustion of hydrocarbons and are commonly released into the environment during fossil fuel combustion, oil refinement, and industrial and municipal discharges.<sup>1</sup> PAHs are recalcitrant and have high carcinogenicity and mutagenicity, especially after they are concentrated by biological chain.<sup>2</sup> They could induce oxidative stress and oxidative DNA damage through the metabolic activation and the generation of reactive oxygen species, so they have become appreciable environmental concerns around the world.<sup>3-5</sup>

Various analytical methods have been developed and applied for monitoring PAHs in the natural environment, such as high performance liquid chromatography with fluorescence detection (HPLC-FLD)<sup>6, 7</sup> and gas chromatography-mass spectrometry (GC-MS)<sup>8, 9</sup>. However, considering complicated sample matrices and trace amount of analytes existed in environment, sample clean-up and preconcentration become necessary to improve detection sensitivity and selectivity, so as to adapt to analytical instruments.

In last decades, a variety of extraction methods have been developed for preparing environmental samples, including solid-phase micro-extraction (SPME),<sup>10</sup> <sup>11</sup> liquid-phase micro-extraction (LPME),<sup>12, 13</sup> dispersive liquid-liquid micro-extraction (DLLME),<sup>14</sup> microwave-assisted headspace solid-phase micro-extraction (MA-HS-SPME),<sup>15, 16</sup> and solid-phase extraction (SPE).<sup>17, 18</sup> SPE has advantages of high recovery, short extraction time, high enrichment factor, low consumption of

1  
2  
3  
4 organic solvents, and ease of automation and operation. However, adsorbents with  
5  
6 superior properties play key role in SPE for enhancing enrichment efficiency and  
7  
8 analytical performance. Nowadays, multiple materials have been synthesized and  
9  
10 utilized as SPE sorbents, including multi-walled carbon nanotubes (MWCNTs),<sup>19, 20</sup>  
11  
12 graphene,<sup>21, 22</sup> magnetic nanoparticle,<sup>23, 24</sup> and metal-organic framework<sup>25</sup>. However,  
13  
14 the synthesis process of such materials are rather complex and often consume large  
15  
16 amounts of organic solvents and time. Therefore, new materials with simple  
17  
18 preparation process are still highly desired.  
19  
20  
21  
22  
23

24 Natural fiber is a very important material and widely used in many areas. For  
25  
26 example, hemp fiber is applied to absorb heavy metal ions from aqueous solutions.<sup>26</sup>  
27  
28 Choi et al. reported that cotton, milkweed, and kenaf have great sorption capacities for  
29  
30 oil with sorption properties 1.5-3 times better than that of polypropylene fibers.<sup>27, 28</sup>  
31  
32 As a kind of natural fiber, cotton fiber mainly consists of cellulose which is  
33  
34 polysaccharide composed mainly of carbon, oxygen, and hydrogen (scheme 1).  
35  
36 Jonker and Zhang have reported that cellulose exhibited an ability to adsorb PAHs  
37  
38 from water with cellulose–water partition coefficients ranging from 3.80 to 5.64.<sup>29, 30</sup>  
39  
40 Liu et al. used cotton as a sorbent for on-line precolumn to enrich PAHs from  
41  
42 waters,<sup>31</sup> however, only four kinds of PAHs have been investigated with high  
43  
44 detection limits and PAHs had not been detected in the real sample. Takagai et al.  
45  
46 applied blue cotton, cotton modified with blue pigment copper(II) phthalocyanine  
47  
48 trisulfonate, as sorbent to enrich PAHs.<sup>32</sup>  
49  
50  
51  
52  
53  
54  
55

56 In the present work, natural cotton fiber was used as SPE adsorbent to enrich  
57  
58  
59  
60

1  
2  
3  
4 PAHs from real water samples. The green material was easy to get, without  
5  
6 preparation and chemical modification, and convenient for usage in PAHs adsorption  
7  
8 and desorption with only by acetonitrile. Under optimal conditions, highly sensitive  
9  
10 detection for seven PAHs was achieved, and to the best of our knowledge, it is the  
11  
12 first time for such material to be successfully applied for real environmental samples  
13  
14 analysis. Thereby, natural cotton fiber proves its promising application in sample  
15  
16 enrichment and analysis.

## 24 **2. Experimental**

### 25 **2.1. Chemicals and materials**

26  
27  
28  
29 The certified reference standards of fluorine (Flu), anthracene (Ant), fluoranthene  
30  
31 (FlA), pyrene (Pyr), benzo[a]anthracene (BaA), benzo[b]fluoranthene (BbF) and  
32  
33 benzo[k]fluoranthene (BkF) were purchased from Acros Organics (NJ, USA). Stock  
34  
35 solutions of these PAHs at the concentration of 100  $\mu\text{g/mL}$  (Flu, Ant, Pyr ), 1000  
36  
37  $\mu\text{g/mL}$  (FlA, BaA) and 50  $\mu\text{g/mL}$  (BbF, BkF) were prepared in methanol. To achieve a  
38  
39 response at the same level in HPLC-FLD detection, the standard mixture of PAHs was  
40  
41 composed of Flu (1.5  $\mu\text{g/mL}$ ), Ant (4  $\mu\text{g/mL}$ ), FlA (8  $\mu\text{g/mL}$ ), Pyr (4  $\mu\text{g/mL}$ ), BaA  
42  
43 (1.5  $\mu\text{g/mL}$ ), BbF (1.5  $\mu\text{g/mL}$ ) and BkF (0.4  $\mu\text{g/mL}$ ) which were diluted from their  
44  
45 stock solutions with methanol. n-Hexane and dichloromethane were purchased from  
46  
47 Sinopharm Chemical Reagent (Shanghai, China), while HPLC grade methanol and  
48  
49 acetonitrile were purchased from Merck (Darmstadt, Germany). The cotton fiber was  
50  
51 purchased from Zhenxiang Labor Protection Product Company (Changsha, China).  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 Titanium wire was obtained from Lihua Non-ferrous Metals Co., Ltd (Baoji, China).

4  
5  
6 Ultrapure water was prepared by MilliQ system (Bedford, USA). Working solutions  
7  
8  
9 were freshly prepared by diluting mixed standard solution with methanol to required  
10  
11 concentrations. All standards and working solutions were stored at 4 °C.  
12

## 13 **2.2. Instrumentation**

14  
15  
16 HPLC analysis of PAHs was performed with a Shimadzu (Tokyo, Japan) LC-20AT  
17  
18 liquid chromatograph equipped with a Shimadzu RF-10A XL fluorescence detector  
19  
20 and a CTO-10AS VP column oven. A Diamonsil C<sub>18</sub> column (250 mm × 4.6 mm,  
21  
22 particle size 5 μm; Dikma Technologies, China) was used for separation. Ultrasonic  
23  
24 wash and elution were operated by a B5500S-DTH ultrasonic machine (Branson,  
25  
26  
27  
28  
29 USA).

## 30 **2.3. Water samples collection**

31  
32  
33 The water samples selected for the investigation included river water sample  
34  
35 collected from the Xiangjiang River (Changsha, China), snow water sample collected  
36  
37 from Yuelu Mountain (Changsha, China) and factory waste water collected from a  
38  
39 metal-fabrication factory (Changsha, China). Before experiments, all the water  
40  
41 samples were filtered through 0.22 μm micropore membranes and stored at 4 °C in  
42  
43  
44  
45  
46  
47 refrigerator.

## 48 **2.4. Preparation of cotton fibers**

49  
50  
51 The cotton fibers were cut into 5 cm of each section ( $55 \pm 2$  mg,  $\Phi$ : 1.80 mm) by  
52  
53  
54 scissors and fixed at a titanium wire. To increase the contact area between the fiber  
55  
56  
57 and the sample to improve the enrichment efficiency, the cotton fibers were unraveled  
58  
59  
60

1  
2  
3  
4 until each cotton are separated as shown in scheme 1, and then ultrasonic washed by  
5  
6 acetonitrile for about 10 min at room temperature.  
7

## 8 9 **2.5. SPE Procedure**

10  
11 The SPE procedure is schematically shown in scheme 1. Briefly, extraction process  
12  
13 was performed in a 50 mL glass vial containing 50 mL of sample solution. A cotton  
14  
15 fiber was directly immersed in the sample solution for 1 h under constant stirring at  
16  
17 room temperature. After extraction, the extracted PAHs were ultrasonically eluted  
18  
19 from the cotton fibers by 3×2 mL of acetonitrile. The eluate was collected and dried to  
20  
21 about 200 μL under a gentle nitrogen stream, and then reconstituted to 500 μL by  
22  
23 acetonitrile. Finally, 20 μL of this solution was injected directly into the HPLC system  
24  
25 for analysis.  
26  
27  
28  
29

## 30 31 **2.6. HPLC-FLD analysis**

32  
33 Determination of PAHs was carried out by a HPLC-FLD system. Chromatographic  
34  
35 analysis was performed using a Diamonsil C<sub>18</sub> column maintained at 30 °C. The  
36  
37 mobile phase consisted of water (solvent A) and acetonitrile (solvent B) and the flow  
38  
39 rate was 1 mL min<sup>-1</sup>. The gradient elution program was set as follows: maintained  
40  
41 75% B for 15 min; then increased B to 90% in 3 min, and kept from 18 min to 26 min;  
42  
43 at last, decreased B to 75% at 27 min and kept for 5 min to equilibrate the column.  
44  
45  
46  
47  
48 The time program of fluorescence detection is given in Table S1.  
49  
50

## 51 52 **3. Results and discussion**

### 53 54 **3.1. Optimization of SPE procedure** 55 56 57 58 59 60

1  
2  
3  
4 In order to achieve accurate and sensitive chromatographic quantification of  
5  
6 trace PAHs in samples, the optimum conditions for SPE using cotton fibers were  
7  
8 investigated. Several conditions affecting the extraction efficiency were optimized,  
9  
10 including elution solvent, ultrasonic elution time, extraction time, sample volume,  
11  
12 volume of organic modifier, and salt concentration. Optimization experiments were  
13  
14 performed using standard aqueous solution of PAHs containing 0.75 µg/mL Flu, 2  
15  
16 µg/mL Ant, 4 µg/mL FIA, 2 µg/mL Pyr, 0.75 µg/mL BaA, 0.75 µg/mL BbF, and 0.2  
17  
18 µg/mL BkF to ensure relatively the same level of responses to each compound.  
19  
20  
21  
22  
23

### 24 **3.1.1. Optimization of desorption conditions**

25  
26 As far as SPE method is concerned, analyte desorption from adsorbent can  
27  
28 significantly affect analyte extraction sensitivity. Thereby, proper elution solvent plays  
29  
30 key role in the process. According to the properties of PAHs, methanol,  
31  
32 dichloromethane, n-hexane and acetonitrile were selected as possible solvents in this  
33  
34 experiment. As shown in Fig. 1, n-hexane has a poor eluting power toward the targets.  
35  
36 Dichloromethane yields the highest recovery for BaA, while acetonitrile is preferable  
37  
38 to Flu, Ant, FIA, Pyr, BbF and BkF. Therefore, acetonitrile was chosen as elution  
39  
40 solvent and used for further studies.  
41  
42  
43  
44  
45

46  
47 Meanwhile, the elution efficiency also relies on the volume of elution solvent. As  
48  
49 shown in Fig. S1, for most of PAHs, the recovery increased with eluent volume  
50  
51 increasing from 2 to 6 mL, which remains nearly unchanged with volume further  
52  
53 increasing from 6 to 8 mL. Considering the elution solvent consumption and time  
54  
55 consuming, 6 mL (2 mL each for three times) of acetonitrile was selected for  
56  
57  
58  
59  
60

1  
2  
3  
4 desorption.

5  
6 In order to resolve any possible carryover problem and avoid the loss of PAHs, the  
7  
8 ultrasonic desorption time was further optimized. The process of desorption was  
9  
10 carried out in an ultrasonic mode with desorption times of 1, 3, 5 and 10 min,  
11  
12 respectively. The results shown in Fig. S2 prove that peak areas of PAHs increased  
13  
14 with desorption time increasing from 1 to 5 min, while remain unchanged with  
15  
16 desorption time elongation. Thus 5 min was sufficient to achieve maximum  
17  
18 desorption. Mosier et al. reported that Trypan blue, a polyaromatic, planar molecule  
19  
20 was irreversibly adsorbed to cotton cellulose at temperatures of  $<120^{\circ}\text{C}$ <sup>33</sup>, probably  
21  
22 induced by amino, sulfo and aromatic group of Trypan blue. Thereby, PAHs  
23  
24 desorption from cotton fibers with only poly-aromatic groups, was rather easy to  
25  
26 happen. That is why 5 min was enough for PAHs desorption, which was chosen as  
27  
28 optimized desorption time.  
29  
30  
31  
32  
33  
34  
35

### 36 37 **3.1.2. Effect of salt concentration and organic modifier**

38  
39 Salt ion in sample might also affect SPE by the competitive interaction between the  
40  
41 salting-out and the salting-in effect, a widely accepted mechanism. The salting-out  
42  
43 effect induces analyte solubility decreasing in water and enhances its partition onto  
44  
45 the fiber, while salting-in effect leads to an opposite result. Hence, the effect of the  
46  
47 addition of salt to the samples was investigated. As shown in Fig. S3, no obvious  
48  
49 change was observed for the recoveries with KCl at 0 – 200 mM, indicating salt ion  
50  
51 addition does not affect extraction efficiency. Salt ion had been reported to enhance  
52  
53 polar compounds recoveries.<sup>34</sup> Considering low polarity of seven PAHs, the reason  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 for above results was understandable. Thereby, no salt was added in the following  
5  
6 experiments.  
7

8  
9 Meanwhile, organic modifier addition, such as methanol might also promote SPE  
10  
11 extraction efficiency, by avoiding carbon chains from cross-linking and completely  
12  
13 contact with target analytes<sup>7</sup>. Thereby, organic modifier volume was investigated.  
14  
15 However, methanol of 0 to 3 mL addition results in no actual changes in extraction  
16  
17 efficiency as shown in Fig. S4. It probably resulted from that cellulose with  
18  
19 hydrophilic groups spreading out well in water. Therefore, no organic modifier is  
20  
21 needed.  
22  
23  
24

25  
26 The above results indicated that the cotton fiber as sorbent was stable in various  
27  
28 solutions, and the extraction efficiency was independent of the salinity and organic  
29  
30 modifier.  
31  
32

### 33 34 **3.1.3. Effect of sample volume**

35  
36 To obtain high concentration factors and satisfactory recoveries for all analytes, as  
37  
38 well as reliable analytical results, sample initial volume as large as possible was  
39  
40 recommended. Therefore, a series of aqueous solution volume (20 – 250 mL) were  
41  
42 investigated. It was found the highest extraction efficiency was obtained with sample  
43  
44 volume of 50 mL, as shown in Fig. 2. In contrast, only below 50% recoveries of  
45  
46 PAHs was achieved with sample volume increasing up to 100 mL, inferring its  
47  
48 insufficient extraction efficiency. Thereby, initial sample volume was set at 50 mL for  
49  
50 further SPE process.  
51  
52  
53  
54

### 55 56 **3.1.4. Optimization of extraction time**

57  
58  
59  
60

1  
2  
3  
4 Furthermore, extraction time as another key factor was also investigated. Extraction  
5  
6 time was set ranging from 15 to 90 min. As shown in Fig. 3, recoveries of all targets  
7  
8 increased with extraction time altering from 15 to 60 min, and remain unchanged even  
9  
10 when time up to 90 min, inferring extraction equilibrium achieved at about 60 min,  
11  
12 which was selected for this work.  
13  
14

### 15 16 **3.2. Regeneration and reusability**

17  
18 The durability of cotton fiber was also investigated by extracting PAHs from water  
19  
20 sample for 30 times. The cotton fiber was regenerated ultrasonically in 10 mL  
21  
22 acetonitrile for 10 min. The extraction efficiency was almost unchanged for the cotton  
23  
24 fiber after 30 times extractions, and the results are shown in Fig. 4. The results  
25  
26 indicate that the cotton fibers can be repeatedly used for extraction.  
27  
28  
29

### 30 31 **3.3. Method performance**

32  
33 Under the optimized extraction conditions, the performance of the proposed SPE  
34  
35 method was evaluated using 50 mL ultrapure water samples spiked with different  
36  
37 analytes concentrations. Quantitative parameters of the proposed method including  
38  
39 linear range, correlation coefficients ( $R^2$ ), limit of detections (LODs), and RSDs are  
40  
41 listed in Table 1. The linear range from 0.025 to 30 mg/L with  $R^2$  ranging from  
42  
43 0.9964 to 0.9999 for all target analytes were obtained. The LODs calculated on the  
44  
45 basis of a signal/noise (S/N) ratio of 3 were 0.38 ng/L for Flu, BaA and BbF, 2.00  
46  
47 ng/L for Ant, 0.80 ng/L for FlA, 1.00 ng/L for Pyr, and 0.10 ng/L for BkF,  
48  
49 respectively. According the Drinking Water Directive (98/83/EC) of the European  
50  
51 Union and the Standards for Drinking Water Quality (GB 5749—2006) from China,  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 the total content of PAHs must under 100 ng/L in drink water. Thus, the method of  
5  
6 this paper meets the requirement for real water analysis.  
7

### 8 9 **3. 4 Environmental water sample analysis**

10  
11 Subsequently, the method developed was applied for PAHs detection in  
12  
13 environmental real water samples: river water, snow water and factory waste water.  
14  
15 Quintuplicate analyses were performed and the recoveries, concentrations found for  
16  
17 the target compound and RSD are summarized in Table 2. Among the three kinds of  
18  
19 environmental samples, PAHs were not detected in snow water; Only Flu was  
20  
21 detected in the metal-fabrication factory waste water with a concentration of 22.6  
22  
23 ng/L. Then seven river water samples were analyzed, collected from different spots in  
24  
25 Xiangjiang River with detail spots shown in Fig. 5. In (A) point at the outlet of  
26  
27 wastewater, Flu, Pyr, BaA, BbF and BkF were detected at 31.9 ng/L, 50.3 ng/L, 83.1  
28  
29 ng/L, 79.4 ng/L, 21.3 ng/L, respectively (shown in Table 3); while in (F) point of a  
30  
31 dock, BbF and BkF were also detected at 41.5 ng/L, and 13.2 ng/L, respectively,  
32  
33 suggesting PAHs mainly come from the wastewater. Method accuracy was evaluated  
34  
35 by relative recovery of spiked real water samples at three concentration levels.  
36  
37 Relative recoveries in range of 70.69 – 110.04% have been successfully achieved.  
38  
39 These above results indicated that our established method could be successfully  
40  
41 applied in PAHs analysis in real water samples. The typical chromatograms of the  
42  
43 snow water, waste water, river water samples and standard spiked solution were  
44  
45 presented in Fig. 6.

### 55 56 **3.5 Comparison with other methods**

57  
58  
59  
60

1  
2  
3  
4 The present method with the cotton fiber as absorbent was also compared with  
5  
6 other materials reported in literatures (as shown in Table 4).<sup>35-37</sup> The time and organic  
7  
8 solvent required in sorbent preparation and limits of detection (LOD) were contrasted.  
9  
10 LODs achieved in present paper are lower or comparable with that of reported.  
11  
12 Furthermore, cotton fiber as sorbent has obvious advantages: considering previous  
13  
14 SPE sorbent synthesis requires several days and dozens or hundreds mL of organic  
15  
16 solvent, resulted in time-consuming and environment pollution, cotton fiber without  
17  
18 any modification needs only 10 min ultrasonic washing with several mL of  
19  
20 acetonitrile. Therefore, cotton fiber is proven to be a green, convenient, efficient and  
21  
22 reliable material for the pre-concentration of trace PAHs from environmental water  
23  
24 samples.

#### 36 **4. Conclusion**

37  
38  
39 In summary, we directly and successfully applied cotton fiber as SPE adsorbent  
40  
41 for PAHs analysis in real environmental water samples. LODs of the developed  
42  
43 method for seven PAH compounds was achieved at 0.1 – 2 ng/L, correspondingly.  
44  
45 Compared to traditional SPE methods, the present sorbent is easy to prepare and  
46  
47 simple to regenerate, which can meet the need for rapid analysis. In addition, cost in  
48  
49 cotton fiber adsorbent preparation is much lower than reported methods, with much  
50  
51 less organic solvent consumption; Furthermore, cotton fiber can be regeneration and  
52  
53 re-usage for more than 30 times, considering its degradable, which is friendly to  
54  
55  
56  
57  
58  
59  
60

environment. Thereby, the green and inexpensive material implied great potential for analyzing PAHs in environmental water samples.

(a): Not detected

(b): sample (H) was snow water sample collected in Yuelu Mountain

(c): sample (I) was waste water collected in a metal-fabrication factory

Table 4 Comparisons of analytical performances of the developed method with those in literature.

| Method   | Sorbent preparation cost (per time) |                        |                                    | Number of analytes | LOD (ng L <sup>-1</sup> ) | References      |
|----------|-------------------------------------|------------------------|------------------------------------|--------------------|---------------------------|-----------------|
|          | Material                            | Time(h) <sup>(a)</sup> | Organic solvent(ml) <sup>(b)</sup> |                    |                           |                 |
| MIPs-SPE | imprinted sol-gel adsorbent         | 38                     | 90                                 | 16                 | 5.2–12.6                  | [35]            |
| MSPE     | TPA-functionalized MNPs             | 37.5                   | 104                                | 6                  | 0.04–3.75                 | [36]            |
| μ-SPE    | functionalized graphene sheet       | 29.5                   | -                                  | 7                  | 0.8–3.9                   | [37]            |
| SPE      | Cotton fiber                        | 0.5                    | -                                  | 7                  | 0.1–2                     | Proposed method |

(a) Experiment operation time was not counted.

(b) Wash solvent was not counted.

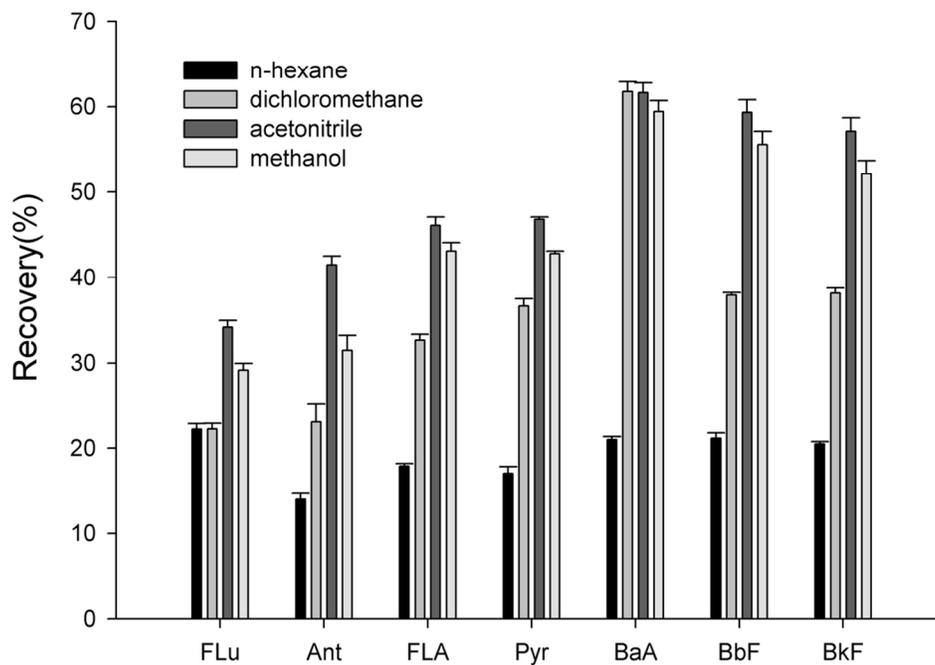

Figure 1. Effect of different eluting solvent on SPE performance. Extraction conditions: sample volume, 50 mL; extraction time: 60 min; eluent volume, 2 mL; ultrasonic desorption time, 10 min.  
109x80mm (300 x 300 DPI)

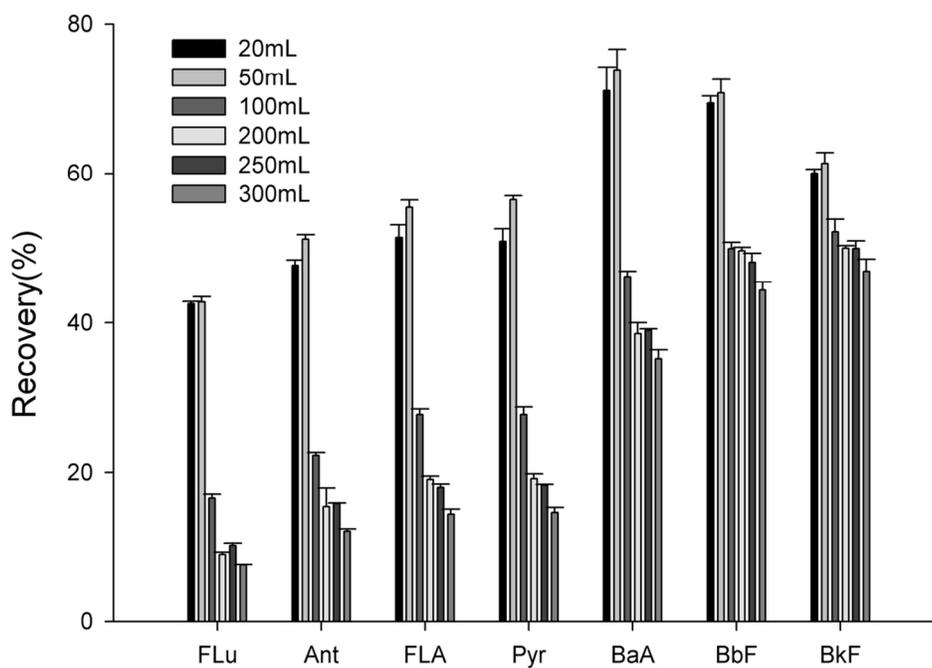

Figure 2. Effect of sample volume. Extraction conditions: extraction time: 60 min; eluent solvent, acetonitrile; volume of elution solvent, 3×2 mL; ultrasonic desorption time, 5 min.  
109x80mm (300 x 300 DPI)

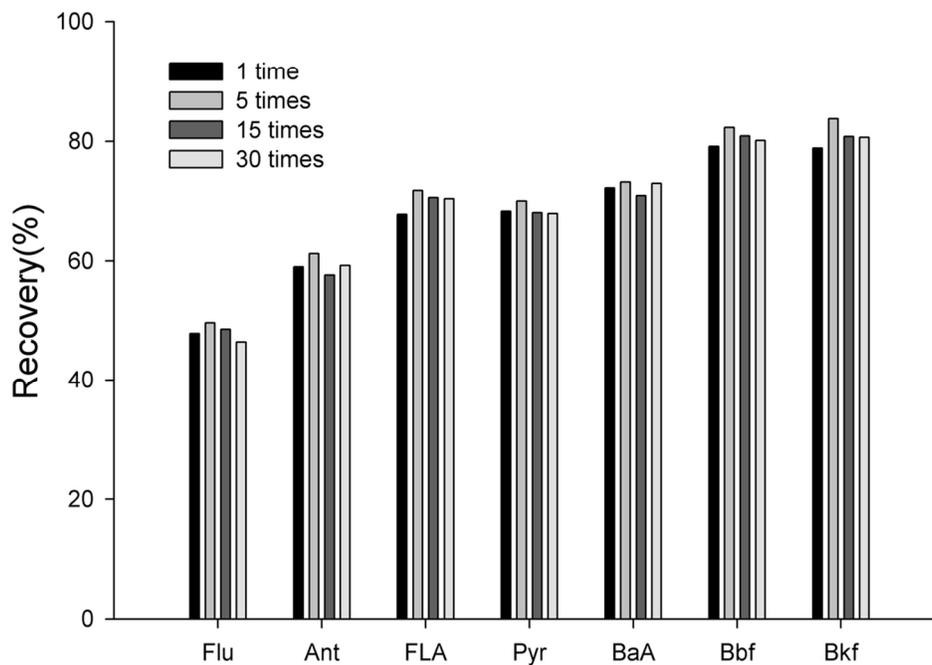

Figure 4. Regeneration and reusability. Extraction conditions: extraction time: 60 min; eluent solvent, acetonitrile; volume of elution solvent, 3×2 mL; ultrasonic desorption time, 5 min.  
109x80mm (300 x 300 DPI)

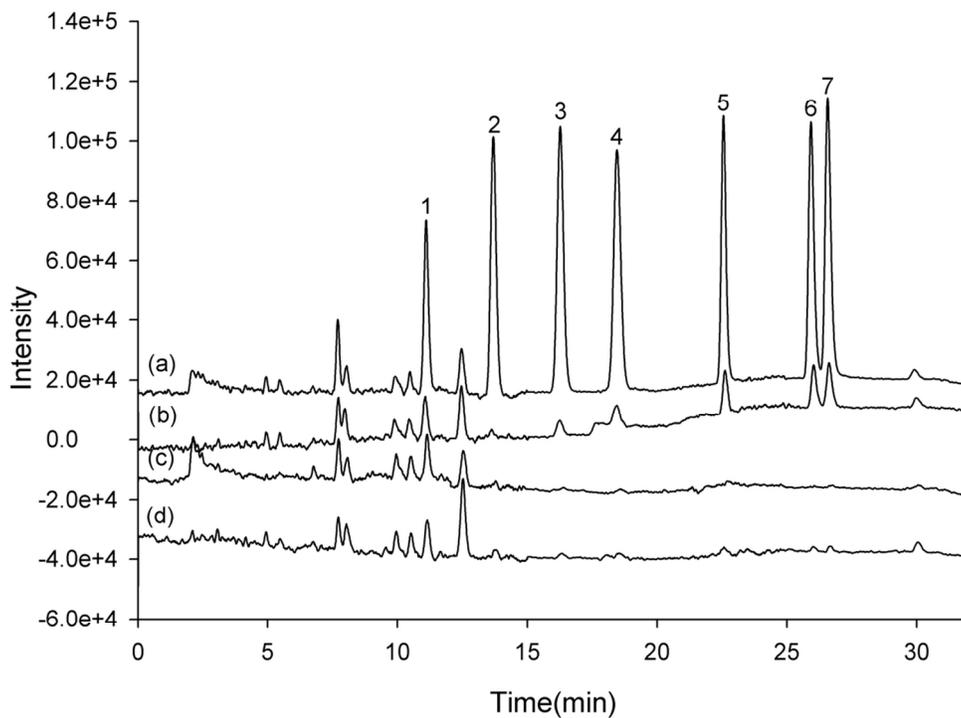

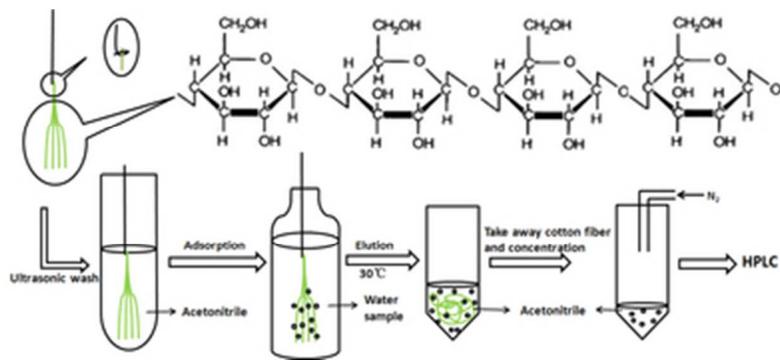

Figure 6. Chromatograms of PAHs in samples: (a) factory waste water spiked with 0.75  $\mu\text{g/L}$  Flu, 2  $\mu\text{g/L}$  Ant, 4  $\mu\text{g/L}$  FIA, 2  $\mu\text{g/L}$  Pyr, 0.75  $\mu\text{g/L}$  BaA, 0.75  $\mu\text{g/L}$  BbF and 0.2  $\mu\text{g/L}$  BkF. Peaks: (1) Flu; (2) Ant; (3) FIA; (4) Pyr; (5) BaA; (6) BbF; (7) BkF; (b) Xiangjiang River water; (c) factory waste water; (d) snow water.  
109x80mm (300 x 300 DPI)

Scheme 1. Structural formula of cellulose and the SPE procedure.  
34x14mm (300 x 300 DPI)
