7 A multiplexed immunoassay method was proposed for sequential detection of two
8 proteins in a single run based on a novel chemiluminescence (CL) reaction
9 kinetics-resolved strategy. This method was established by using acridinium ester (AE)
10 and alkaline phosphatase (ALP) as the signal probes due to the significant difference in
11 their CL reaction kinetics characteristics. Mouse IgG (MIgG) and mouse IgM (MIgM)
12 were detected as the model analytes with a competitive immunoassay format. AE and
13 ALP were used to tag goat anti-mouse IgG and rabbit anti-mouse IgM, respectively, to
14 form two immunocomplexes. The two CL reactions with flash type and glow type
15 kinetics characteristics were triggered simultaneously by adding the coreactants, then the
16 CL signals from the two reactions were recorded after 0.2 s and 500 s of the reaction
17 triggering, respectively. The multiplexed CL immunoassay provided a wide range of
18 0.50-200 ng mL⁻¹, with a low detection limit of 0.16 ng mL⁻¹ (S/N = 3) for both MIgG
19 and MIgM. Additionally, no obvious signal overlap was observed in the multiplexed
20 immunoassay. The proposed method was successfully applied for the detection of MIgG
21 and MIgM levels in mouse serums, and the results were in good agreement with those
22 from the reference ELISA method. We anticipate that it can be used in some other areas
23 such as drug screening, food safety, environment monitoring and clinical diagnosis.

1. Introduction

There is an increasing interest in developing multiplexed immunoassay that can substitute parallel single-analyte immunoassays in clinical diagnosis, environmental monitoring, and biodefense applications.¹ Multiplexed immunoassay shows some unique advantages, such as less sample consumption, shorter assay time, minimized repetitions of tedious procedures, and lower cost per test, in comparison with conventional parallel single analyte detection. Moreover, it is convenient for the analysis of some complex real samples, such as biological or environmental samples, in which many different analytes can interfere with the signal of a specific sensor.²

Nowadays, array mode and multi-label mode have been widely utilized in multiplexed immunoassay.³ For array mode, a universal signal probe is usually utilized to tag all analytes for fluorescent,⁴ colorimetric,⁵ chemiluminescent (CL),⁶⁻⁸ electrochemical⁹⁻¹¹ or surface-enhanced Raman spectroscopic¹² detection. These methods sometimes encounter signal cross-talk between the adjacent detection zones resulting from diffusion of the active product.¹³ When multi-label mode is employed, multiple signal probes are used to tag different antibodies or antigens corresponding to the analytes (one per analyte), in which the labels include enzymes,^{14,15} metal ions,¹⁶ fluorescent dyes¹⁷ and nanoparticles.^{18,19} For this mode wavelength^{15,17,19} and potential^{14,18} were usually utilized to distinguish the signal of one label from the others. However, such multi-label based multiplexed immunoassays are often limited by overlap of signals from different labels due to their broad signal band.²⁰ In view of the above, it is still a challenge to construct multiplexed immunoassays free of signal overlap based on the multi-label mode.

Compared with other multiplexed immunoassays, chemiluminescent immunoassay

1
2
3
4
5
6 (CLIA) has shown great potential in terms of its low background and wide linear range.
7
8
9 Furthermore, CL detection is usually conducted on simple and inexpensive
10 instrumentation without external light source and optical splitting system,²¹ which
11 facilitates developing point-of-care diagnosis method using portable detector. Differing
12 from the fluorometric and spectrophotometric approach, CL intensity is the only
13 considered factor in a CL assay, while wavelength is not considered, thus, it is very
14 difficult to distinguish CL signals from different labels.²² Therefore, multiplexed CL
15 detections are commonly established based on array mode.⁶⁻⁸

19
20
21
22
23
24

25 Up to now, most CL systems can be classified into three categories based on their
26 different reaction kinetics characteristics. The first category is flash type showing a
27 short-lived (seconds) but intense signal, including heavy metal ion-catalyzed
28 luminol-H₂O₂ system²³ and acridinium ester (AE)-H₂O₂ system;^{24,25} the second category
29 is glow type indicating a longer-lived (minutes to hours) and continuous increasing CL
30 emission, such as alkaline phosphatase (ALP)-adamantlyl-1,2-dioxetane system;²⁶ and
31 the third category is oscillating type whose CL signal periodically grow and decay, such
32 as Ru(bpy)₃²⁺-catalyzed Belousov-Zhabotinsky system.²⁷ The quite distinct kinetics
33 characteristics of these CL reactions provide a possible pathway to detect multiple
34 analytes in a single run with a reaction kinetics resolution strategy. CL reactions show
35 wide time window ranging from seconds to hours, thus discrimination of signals from
36 different probes can be easily achieved with the aid of a regular timer. However, for
37 time-resolved fluorescent assay which also collects signals from different fluorophores at
38 different time windows, a sophisticated timing instrumentation is required since lifetime
39 of most fluorophores typically ranges from ps to ms level.^{20,28,29}

6 As a typical flash-type CL substance with an emission duration of 0.2 s, AE has been
7 employed in immunoassays because of its high CL efficiency.³⁰
8 ALP-adamantlyl-1,2-dioxetane reaction is a glow type CL system with a signal
9 increasing duration of hours, accomplished with a distinguished sensitivity.²⁶ In this
10 research, a novel reaction kinetics-resolved multiplexed detection strategy was developed
11 by using AE and ALP as the CL labels in immunoassay. Mouse IgG (MIgG) and mouse
12 IgM (MIgM) were detected as the model analytes with a competitive format. After the
13 coreactants were added, the two different CL reactions were triggered simultaneously.
14 However, due to the significant difference in the reaction kinetics characteristics of the
15 labels, the two CL signals can be collected at the different time windows.

31 **2.1 Materials and equipments**

32
33 MIgG, MIgM, mouse IgA (MIgA), polyclonal goat anti-mouse IgG, and ALP-tagged
34 rabbit anti-mouse IgM were all purchased from Beijing Biosynthesis Biotechnology Co.,
35 Ltd. (China). Mouse serum albumin (MSA) and mouse prealbumin (MPA) were
36 purchased from Shanghai Jiahe Biotechnology Co., Ltd. (China). AE labeling kit was
37 provided by Enzo Life Sciences, Inc. (USA), and AE tagging of goat anti-mouse IgG was
38 performed according to the manual. The ELISA kits for MIgG and MIgM were provided
39 by Chongqing Biospes Co., Ltd. (China). Healthy adult Kunming mice were obtained
40 from Chongqing Tengxin Biotechnology Co., Ltd. (China). Blood samples were obtained
41 from eyeballs of the mice, and centrifuged at 3000 rpm for 20 min to obtain sera. ALP
42 substrate solution composed of disodium
43 3-(4-methoxy-spiro{1,2-dioxetane-3,2'-(5'-chloro) tricyclo [3.3.1.1^{3,7}]decan}-4-yl)

1

3
4
5
6 phenyl phosphate (CSPD, a derivative of adamantyl-1,2-dioxetane compound) and
7
8 Sapphire-IITM enhancer were purchased from Boson Biotech. Co., Ltd. (China).
9
10 SuperBlock[®] T20 (Thermo Fisher Scientific Inc., USA) was utilized as the blocking
11
12 buffer. The coating buffer was 0.10 M Tris-HCl buffer at pH 8.0. The dilution buffer for
13
14 the antibodies, the antigens and the tracers all were 0.10 M Tris-HCl buffer at pH 7.2.
15
16 The wash buffer was 0.10 M Tris-HCl buffer at pH 7.4, containing 0.05% Tween-20. All
17
18 aqueous solutions were prepared using ultrapure water (18.2 MΩ) produced by an ELGA
19
20 PURELAB Classic system (UK). All other reagents were analytical reagent grade and
21
22 used without further purification.
23
24
25

26
27 The polystyrene high-affinity 96-well microplate was provided by Greiner Bio-One
28
29 Biochemical Co., Ltd. (Germany). All CL measurements were performed on a MPI-A CL
30
31 analyzer (Xi'an Remax Electronic Science & Technology Co., Ltd., China) equipped with
32
33 a photomultiplier operated at -800 V.
34
35

36 **2.2 Procedure of competitive CLIA**

37

38
39 Each well of the polystyrene microplate was coated at 4 °C for 12 h with 100 μL of a
40
41 mixture of MIgG (20 μL mL⁻¹) and MIgM (10 μL mL⁻¹) dissolved in the coating buffer.
42
43 Subsequently, the well was washed thrice with 260 μL of wash buffer manually and
44
45 blocked with 150 μL of blocking buffer for 90 min at 37 °C. After that, the well was
46
47 washed thrice and filled with 80 μL of sample solution containing MIgG and MIgM at
48
49 different concentrations, followed by the mixture of AE-tagged goat anti-mouse IgG and
50
51 ALP-tagged rabbit anti-mouse IgM (10 μL for each). The competitive immune-reactions
52
53 were allowed to last for 90 min at 37 °C. Then the microplate was washed to remove the
54
55 unbound reactants.
56
57
58
59
60

1
2
3
4
5
6 The CL reactions were triggered by adding 60 μL of freshly prepared coreactants
7 composed of H_2O_2 and ALP substrate in carbonate buffer saline (CBS). The CL signals
8 for MIgG and MIgM were detected at 0.2 s and 500 s after the reactions were triggered,
9 respectively.

15 16 **3. Results and discussion**

17 18 **3.1 The principle of reaction kinetics-resolved CL for multiplexed detection**

19
20 The principle of reaction kinetics-resolved CL strategy for the multiplexed detection of
21 MIgG and MIgM is illustrated in Fig. 1. AE and ALP were adopted as the flash type and
22 glow type CL probes to tag goat anti-mouse IgG and rabbit anti-mouse IgM, respectively.
23
24 Then the AE- and ALP-tagged immunocomplexes were formed in a competitive
25 immunoassay format. Since the two tagged probes showed very different kinetics
26 characteristics, the signals from the different analytes could be sequentially collected in
27 different time windows after the two CL reactions were triggered simultaneously.
28
29
30
31
32
33
34
35
36
37

38 To demonstrate the feasibility of this reaction kinetics-resolved strategy, the kinetics
39 behaviors of the two CL systems were investigated in detail. Fig. 2A presents the
40 individual kinetics curves of the two CL reactions. As seen in this figure, CL emission
41 from AE- H_2O_2 system increased sharply to the maximum at about 0.2 s after the
42 coreactants were added, and then decayed quickly within 10 s (curve a). However, the CL
43 emission from the ALP-CSPD system was very weak within 10 s of reaction triggering,
44 then increased continuously and steadily in a long duration (curve b). Fig. 2B shows CL
45 kinetics curve (curve c) of the mixed reaction system of AE- H_2O_2 and ALP-CSPD. As
46 seen in this figure, the flash type reaction of AE- H_2O_2 system was not obviously affected
47 by the glow type one. However, for the glow type reaction of ALP-CSPD system, the

signal from this CL reaction was found to be obviously affected by the co-existing AE-based CL system at the beginning of the reaction triggering. After 70 s, the CL kinetics curve of the ALP-catalyzed reaction in the mixed system overlapped with that in the individual system, which indicated that the mutual influence was avoided effectively after 70 s.

As seen in Fig. 1, MIgG was detected at 0.2 s since AE-H₂O₂ system showed the maximal emission at this time. For MIgM detection, ALP-CSPD system showing a continuously increased signal was adopted, thus long reaction time resulted in obviously improved signal intensity and detection sensitivity, for example, signals for 100 ng mL⁻¹ MIgM at 700 s and 1000 s showed increase of 38% and 101%, respectively, in comparison with that at 500 s. However, long signal acquisition time led to low assay speed. Five hundredth second was chosen as the time window for MIgM signal detection considering the assay speed. Obviously, at the chosen time windows, the two CL reactions did not show any observable mutual interference. Therefore, multiplexed CLIA can be easily achieved without using any optical splitting system for wavelength discrimination.

3.2 Optimization of CLIA conditions

The performance of immunoassay usually depends on such parameters as the concentrations of the tracer antibodies and the incubation time. The effects of the concentrations of the tracer antibodies on the CL responses were investigated using MIgG (100 ng mL⁻¹), MIgM (100 ng mL⁻¹) and Tris-HCl (as a blank) in parallel. Fig. 3A and B show that the signal-to-blank ratios reached the minimum when the concentrations of the tracer antibodies for MIgG and MIgM were 5.0 μg mL⁻¹ and 1.0 μg mL⁻¹,

1
2
3
4
5
6 respectively, indicating that the competition capability of two analytes in the sample
7
8 against the immobilized antigens was the strongest under this condition. The effect of the
9
10 incubation time on the immunoreactions was also studied in detail. From Fig. 3C and D,
11
12 it was found that the both CL responses almost trended the maximum at 90 min,
13
14 suggesting that the immuno-binding reached the saturation at this incubation time.
15
16 Therefore, the concentrations of $5.0 \mu\text{g mL}^{-1}$ and $1.0 \mu\text{g mL}^{-1}$ for the tracer antibodies for
17
18 MIgG and MIgM, respectively, and the incubation time of 90 min were adopted in the
19
20 further investigation.
21
22
23

24
25 For the CL detection, the pH value and the concentrations of the coreactants were the
26
27 crucial factors influencing the signal intensities and the reaction kinetics characteristics.
28
29 The optimal pH values for AE-H₂O₂ and ALP-CSPD systems were around 13.0³¹⁻³³ and
30
31 9.5,²⁶ respectively. High pH value was found to damage the activity of ALP, thus
32
33 inhibited CL emission from ALP-CSPD system. Meanwhile, AE-H₂O₂ emitted strong CL
34
35 signal only in strong basic medium. Thus, a compromised pH value of 11.6 was adopted
36
37 since the both reaction systems showed acceptable signal intensity and detection
38
39 sensitivity. Also, pH value showed noticeable influence to the reaction kinetics
40
41 characteristics of the both CL reactions, and therefore affected signal resolution. An ideal
42
43 signal resolution was obtained at this compromised pH value. For the same reason, the
44
45 optimal concentrations of H₂O₂, CSPD and Sapphire-IITM enhancer were chosen to be
46
47 20 mM, 67 mM and 0.33 mg mL^{-1} , respectively.
48
49
50
51

52 53 **3.3 Estimation of specificity**

54
55 In order to evaluate the specificity of this immunoassay method, the interferences of
56
57 various species including MIgA, MSA and MPA were investigated since these proteins
58
59
60

1
2
3
4
5
6 exist in the real mouse serum samples. The specificity was estimated by comparing the
7 responses to MIgG, MIgM and the interferent proteins. As shown in Fig. 4, obvious
8 decrease of 30% and 40% in the CL intensity were observed for MIgG and MIgM at 100
9 ng mL⁻¹ since a competitive format was adopted in this method, while MIgA, MSA and
10 MPA at the same concentration all showed negligible decrease below 4.6%. The results
11 suggested that the specificity of the multiplexed detection method for MIgG and MIgM
12 was acceptable for real sample assay.
13
14
15
16
17
18
19
20
21
22

23 **3.4 Performance of CLIA**

24
25 As shown in Fig. 5, under the optimal conditions, the CL responses decreased linearly
26 with the increasing concentrations of MIgG and MIgM since a competitive immunoassay
27 format was adopted. The linear range was 0.50-200 ng mL⁻¹, with a detection limit of
28 0.16 ng mL⁻¹ at a signal to noise ratio of 3, for both MIgG and MIgM. The regression
29 equations could be expressed as $I(\text{a. u.}) = -23.3C(\text{ng mL}^{-1}) + 6837$ and $I(\text{a. u.}) = -26.1C$
30 $(\text{ng mL}^{-1}) + 7543$, with the correlation coefficients of 0.9915 and 0.9818 for MIgG and
31 MIgM, respectively. The reproducibility was assessed by intra- and inter-day relative
32 standard deviations (RSDs) for MIgG and MIgM at low (0.5 ng mL⁻¹), and high (100 ng
33 mL⁻¹) concentrations. As shown in Table 1, the intra- and inter-day RSDs were not higher
34 than 4.5 and 4.9%, respectively.
35
36
37
38
39
40
41
42
43
44
45
46
47
48

49 **3.5 Application in real samples assay**

50
51 In order to further estimate the application potential of this CL reaction
52 kinetics-resolved strategy, the levels of MIgG and MIgM in three healthy adult mouse
53 serum samples were evaluated with this method, and the obtained results were compared
54 with those from the reference ELISA method. All samples were diluted before assay to
55
56
57
58
59
60

1
2
3
4
5
6 ensure that the concentrations were within the linear ranges. From Table 2, it could be
7
8 seen that the two methods showed acceptable agreement. Known amounts of MIgG and
9
10 MIgM were spiked into the diluted samples to perform the recovery tests. The recoveries
11
12 for MIgG and MIgM were 88.0-109.6% and 90.0-112.0%, respectively, demonstrating
13
14 the reliability of this method (Table 3).
15
16

17 18 **4. Conclusions** 19

20
21 In summary, a novel CL reaction kinetics-resolved strategy was designed for
22
23 multiplexed immunoassay by using AE and ALP as the labels. This strategy did not need
24
25 optical splitting system to distinguish the signals from the two CL probes. Due to the very
26
27 different reaction kinetics characteristics of the two CL probes (a flash type and a glow
28
29 type), MIgG and MIgM could be sequentially detected in different time windows with the
30
31 aid of a regular timer. This proposed method was simple, rapid and low-cost. Furthermore,
32
33 no signal overlapping was found in this work, which was frequently encountered in the
34
35 previously reported multiplexed immunoassays based on multi-label mode. The results
36
37 for real sample assay and recovery test demonstrated its reliability and application
38
39 potential. Further work utilizing more CL labels to detect more analytes in a single run is
40
41 still ongoing. We anticipate that this multiplexed detection method can be used in some
42
43 important areas such as drug screening, food safety and clinical diagnosis.

Captions for Figures

Fig. 1. Schematic illustration of the reaction kinetics-resolved CLIA for the multiplexed detection of MIgG and MIgM.

Fig. 2. (A) The CL kinetics curves of (a) the AE-H₂O₂ reaction alone for MIgG (0.5 ng mL⁻¹) detection and (b) the ALP-CSPD reaction alone for MIgM (0.5 ng mL⁻¹) detection. (B) The CL response curve of (c) the mixed CL reactions for MIgG (0.5 ng mL⁻¹) and MIgM (0.5 ng mL⁻¹) detections. All other conditions were the optimal conditions.

Fig. 3. Effect of the concentrations of the tracer antibodies on their corresponding signal-blank-ratios for (A) MIgG and (B) MIgM at 100 ng mL⁻¹. Effect of the incubation times on the CL responses for (C) MIgG and (D) MIgM at 100 ng mL⁻¹. All other conditions were the optimal conditions, $n = 5$.

Fig. 4. The CL responses of MIgG, MIgM, MIgA, MSA, and MPA at 100 ng mL⁻¹. Tris-HCl buffer was used as the blank. All other conditions were the optimal conditions, $n = 5$.

Fig. 5. (A) Enlarged view for the CL responses of MIgG. (B) The CL responses of MIgG and MIgM at the concentrations of (a) 0, (b) 0.5, (c) 25, (d) 50, (e) 100, and (f) 200 ng mL⁻¹. All other conditions were the optimal conditions, $n = 5$.

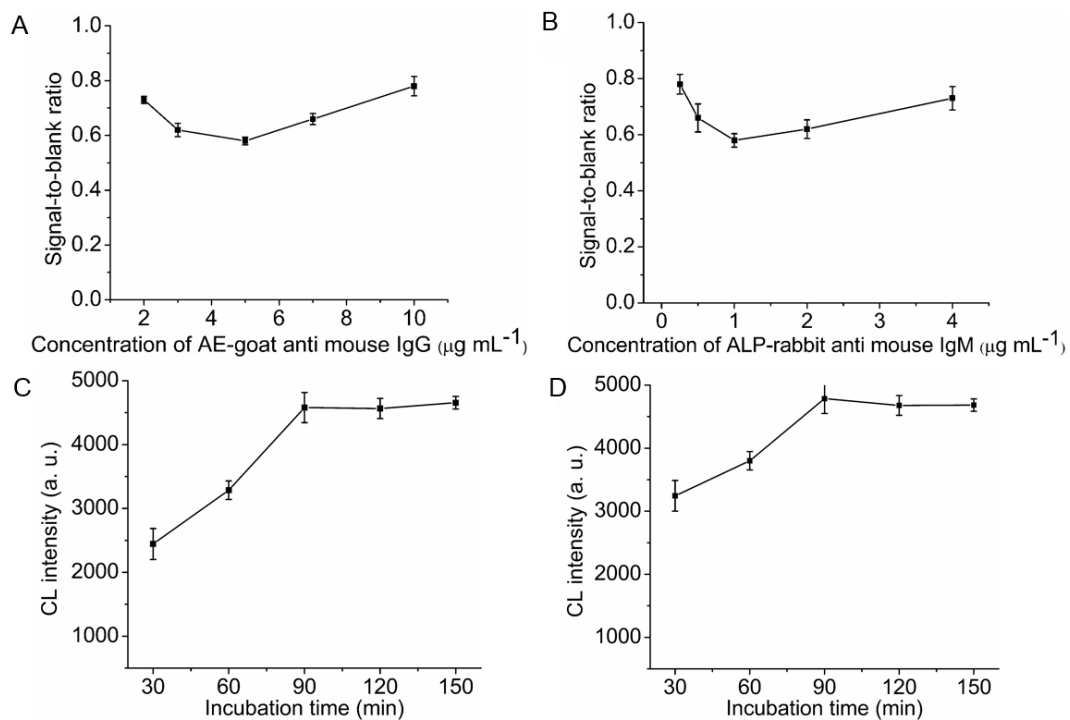

Figure 4

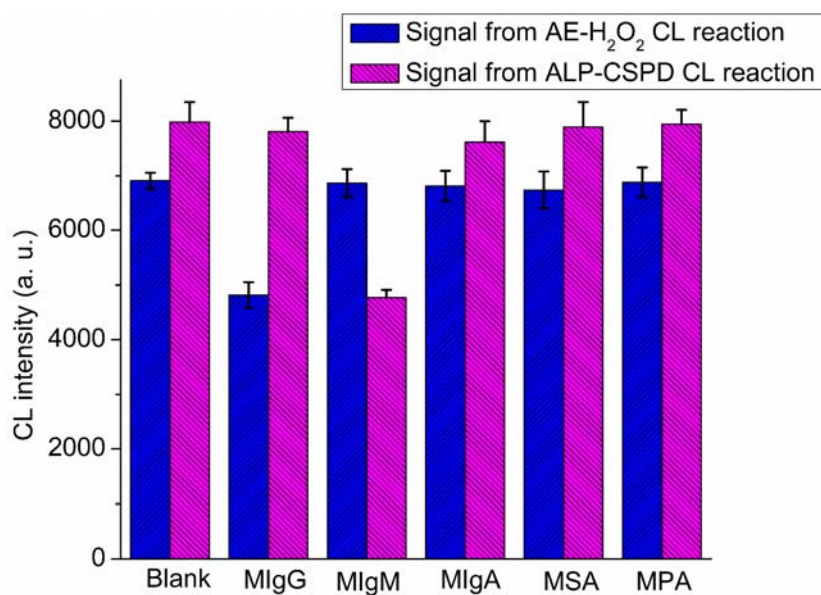

Figure 5

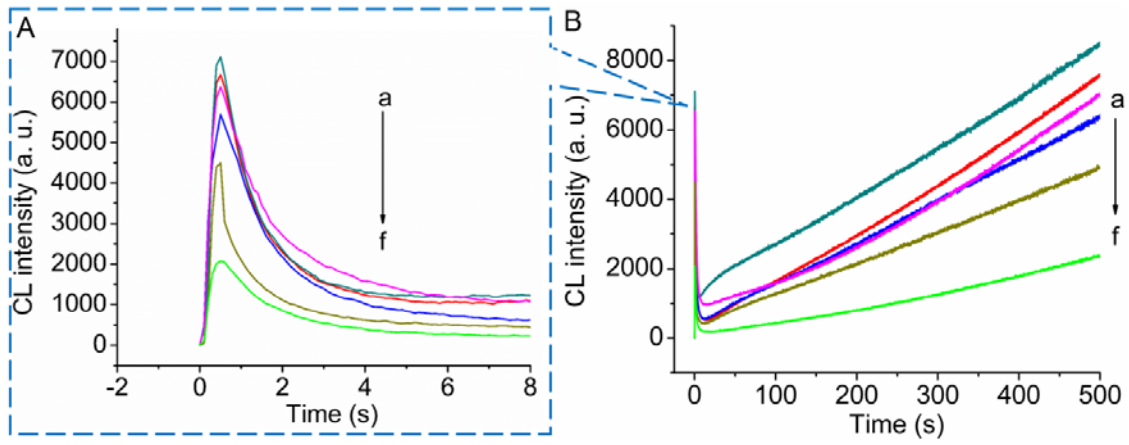

Table 1. Reproducibility for MIgG and MIgM detections ($n = 5$).

Analyte	MIgG		MIgM	
Concentration (ng mL ⁻¹)	0.5	100	0.5	100
Intra-day RSD (%)	1.0	4.5	2.2	4.0
Inter-day RSD (%)	1.1	4.9	3.3	4.7

Table 2. Assay results of the mouse serum samples using the proposed and reference methods ($n = 5$).

Sample no.	Concentration of MIgG (mg mL^{-1})		Concentration of MIgM (mg mL^{-1})	
	^a Proposed method	^b ELISA	^a Proposed method	^b ELISA
1	8.1±0.3	8.4±0.1	0.25±0.07	0.25±0.03
2	6.8±0.1	7.3±0.3	0.22±0.08	0.21±0.01
3	6.4±0.7	6.7±0.2	0.28±0.08	0.26±0.05

^a The samples were 2×10^5 -time diluted, ^b the samples were 100-time diluted.

Table 3. The results of the recovery tests of MIgG and MIgM spiked in the mouse serum samples obtained by the proposed method ($n = 5$).

^a Sample no.	1		2		3	
	MIgG	MIgM	MIgG	MIgM	MIgG	MIgM
Initial (ng mL ⁻¹)	40.5	1.2	34.0	1.1	32.0	1.4
Added (ng mL ⁻¹)	10.0	1.0	25.0	2.5	50.0	5.0
Found (ng mL ⁻¹)	49.3±2.9	2.1±0.1	61.4±1.9	3.7±0.3	82.2±1.1	7.0±0.6
Recovery (%)	88.0	90.0	109.6	104.0	100.4	112.0

^a Mouse serum samples were 2×10^5 -time diluted prior to the recovery test.
