Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

*Accepted Manuscripts* are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

**A turn-on fluorescent probe for hypochlorous acid based on the oxidation of  
diphenyl telluride**

**Abstract**

A fluorescent probe, **HCTe** was developed for rapid detection of hypochlorous acid based on the specific HOCl-promoted oxidation of diphenyl telluride. The reaction is accompanied by a 82-fold increase in the fluorescent quantum yield (from 0.009 to 0.75). The fluorescent turn-on mechanism is achieved by suppression of the photo induced electron transfer (PET) from the diphenyl telluride group to BODIPY. The fluorescence intensity of the reaction between HOCl and **HCTe** is linear in the HOCl concentration range of 1 to 10  $\mu\text{M}$  with a detection limit of 41.3 nM (S/N = 3). In addition, confocal fluorescence microscopy imaging using RAW264.7 macrophages demonstrated that **HCTe** could be an efficient fluorescent probe for HOCl detection in living cells.

## 1. Introduction

Hypochlorous acid (HOCl) is a reactive oxygen species (ROS), which has been used as a highly effective antimicrobial agent in mammalian immune systems.<sup>1,2</sup> Endogenous hypochlorite is formed from the reaction of hydrogen peroxide and chloride ions catalyzed by the heme-containing enzyme, myeloperoxidase (MPO) in leukocytes including macrophages, monocytes, and neutrophils.<sup>3,4</sup> However, excess production of hypochlorous acid in living organisms can cause various diseases, such as arthritis, cardiovascular disease, cancer, inflammatory disease and neuron degeneration.<sup>5-7</sup> Due to its biological importance, the development of highly sensitive and selective fluorescent probes will be useful in the dynamic detection of HOCl in living organisms.

The general approach for the design of HOCl fluorescent probes is to join a HOCl-reactive moiety with an organic fluorophore. HOCl has high oxidation properties. Several functional groups, such as p-alkoxyaniline, p-methoxyphenol, oxime, selenide, and thiol, have been identified as HOCl-reactive moieties.<sup>8-24</sup> The HOCl-reactive moiety functions as a controller that modulates the fluorescence intensity of the fluorophore. Organotellurium compounds are more electron rich than sulfur compounds, and have been used to design probes for some reactive oxygen species (ROS) and reactive nitrogen species (RNS).<sup>25-27</sup> Although several new HOCl sensors have been designed, fluorescent probes based on the redox cycle of tellurium to detect HOCl in living cells have not been studied in detail.

In this work, a new BODIPY (boron-dipyrromethene) based fluorescent probe **HCTe**, bearing an organotellurium group, was designed for HOCl detection (Scheme 1). The diphenyl telluride unit performed as a modulator that responds to the amount of HOCl, while BODIPY was used as the signal transduction unit. **HCTe** has weak fluorescence with a quantum yield of  $\Phi = 0.009$ , due to the photoinduced electron transfer (PET) from the diphenyl telluride group to the BODIPY moiety. However, the strong fluorescence of BODIPY is restored after the oxidation of tellurium by HOCl. This new probe exhibits higher selectivity and sensitivity towards HOCl in aqueous solutions, compared to other ROS and reactive nitrogen species (RNS). Most importantly, **HCTe** shows good cell-membrane permeability and can be successfully applied to image endogenous HOCl in living cells.

## 2. Materials and methods

### 2.1 Materials and Instrumentation

All solvents and reagents were obtained from commercial sources and used without further purification. UV/Vis spectra were recorded on an Agilent 8453 UV/Vis spectrometer. Fluorescence spectra measurements were performed on a Hitachi F-7000 fluorescence spectrophotometer. NMR spectra were obtained on a Bruker

1  
2  
3 DRX-300 and Agilent Unity INOVA-500 NMR spectrometer. Fluorescent images  
4 were taken on a Leica TCS SP5 X AOBS Confocal Fluorescence Microscope.  
5

## 6 **2.2 Preparation of ROS and RNS:**

7 Various ROS and RNS including HOCl,  $\bullet\text{OH}$ ,  $\text{H}_2\text{O}_2$ ,  $^1\text{O}_2$ ,  $\text{NO}_2^-$ ,  $\text{NO}_3^-$ , NO,  $\text{ONOO}^-$ ,  
8  $\text{O}_2$ , and *t*-BuOOH were prepared according to the following methods. HOCl was  
9 prepared from commercial bleach; the concentration of hypochlorite ( $\text{OCl}^-$ ) was  
10 determined by using an extinction coefficient of  $350 \text{ M}^{-1}\text{cm}^{-1}$  (292 nm) at pH 9.0.  
11 Hydroxyl radical ( $\bullet\text{OH}$ ) was generated by Fenton reaction on mixing  
12  $\text{Fe}(\text{NH}_4)_2(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$  with 10 equivalents of  $\text{H}_2\text{O}_2$ ; the concentration of  $\bullet\text{OH}$  was  
13 estimated from the concentration of  $\text{Fe}^{2+}$ . The concentration of the commercially  
14 available stock  $\text{H}_2\text{O}_2$  solution was estimated by optical absorbance at 240 nm. Singlet  
15 oxygen ( $^1\text{O}_2$ ) was generated by the addition of NaOCl and  $\text{H}_2\text{O}_2$  according to the  
16 literature.<sup>28</sup> The source of  $\text{NO}_2^-$  and  $\text{NO}_3^-$  was from  $\text{NaNO}_2$  and  $\text{NaNO}_3$ . Nitric oxide  
17 (NO) was generated from sodium nitroferricyanide(III) dihydrate. Peroxynitrite  
18 ( $\text{ONOO}^-$ ) was prepared as the reported method;<sup>29</sup> the concentration of peroxynitrite  
19 was estimated by using an extinction coefficient of  $1670 \text{ M}^{-1}\text{cm}^{-1}$  (302 nm).  
20 Superoxide ( $\text{O}_2^-$ ) is prepared from  $\text{KO}_2$ . *t*-BuOOH was obtained commercially from  
21 Alfa Aesar.

## 31 **2.3 Synthesis of 2-(phenyltellanyl) benzaldehyde:**

32 To a mixture of CuI (11.59 mg, 0.05mmol) and 2,2'- dipyridyl (9.56 mg, 0.05  
33 mmol) in DMSO (1 mL) and  $\text{H}_2\text{O}$  (1 mL), biphenyl ditelluride (500 mg, 1.22 mmol)  
34 and 2-formyl phenyl boronic acid (546 mg, 3.66 mmol) were added. The reaction  
35 mixture was stirred at  $100^\circ\text{C}$  for 5 hr in air. The reaction mixture was diluted with  
36 water and extracted with dichloromethane. The combined organic layer was dried  
37 over anhydrous  $\text{MgSO}_4$  and the solvent was removed under reduced pressure. The  
38 crude product was purified by column chromatography (hexane: dichloromethane =  
39 1:1) to give the compound as a yellow oil. Yield: 300 mg (55%).  $^1\text{H}$  NMR (300 MHz,  
40  $\text{CDCl}_3$ ):  $\delta$  9.91 (s, 1H), 7.85 (d,  $J = 7.2$  Hz, 2H), 7.63 (m, 4H), 7.39 (t,  $J = 6.6$  Hz, 1H),  
41 7.31 (t,  $J = 7.5$  Hz, 2H);  $^{13}\text{C}$  NMR (75 MHz,  $\text{CDCl}_3$ ):  $\delta$  191.7, 140.0, 138.0, 135.7,  
42 135.2, 130.0, 129.1, 127.0, 113.2. MS (ESI<sup>+</sup>):  $m/z = 312.9$  [M + H]<sup>+</sup>; HRMS (ESI<sup>+</sup>):  
43 Calcd. for  $\text{C}_{13}\text{H}_{10}\text{OTe}$ , 312.9872 [M + H]<sup>+</sup>; found, 312.9862 [M + H]<sup>+</sup>. FTIR ( $\text{cm}^{-1}$ )

## 54 **2.4 Synthesis procedure of HCTe**

55 TFA (0.1 mL) was added to the solution of 2-(phenyltellanyl)benzaldehyde  
56 (300 mg, 0.682 mmol) and ,2,4-dimethylpyrrole (136.40 mg, 1.433 mmol) in  $\text{CH}_2\text{Cl}_2$   
57  
58  
59  
60

(100 mL) under N<sub>2</sub> atmosphere. After the solution was stirred for 6 h, TLC analysis revealed complete conversion of starting materials to the dipyrromethane. To the reaction mixture, DDQ (170 mg, 0.7502 mmol) dissolved in CH<sub>2</sub>Cl<sub>2</sub> (50 mL) was added. Then, the solution was stirred for further 1h; TLC analysis revealed the complete disappearance of dipyrromethane and formation of the desired dipyrromethene. Triethyl amine (4.0 mL) and BF<sub>3</sub>.Et<sub>2</sub>O (4.0 mL) were added to the reaction mixture and stirring was continued for further 5 h. Reaction mixture was washed with water (50 mL) by three times and the organic phase was dried over anhydrous MgSO<sub>4</sub>. The solvent was removed under reduced pressure and the crude product was purified by column chromatography (hexane : dichloromethane = 1:1) to give the compound **HCTe** as a red solid. Yield: 290 mg (80 %); melting point 129-130 °C. <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>): δ 7.86 (d, *J* = 6.9 Hz, 2H), 7.42-7.18 (m, 7H), 6.01 (s, 2H), 2.61 (s, 6H), 1.50 (s, 6H); <sup>13</sup>C NMR (75 MHz, CDCl<sub>3</sub>) δ 156.2, 142.7, 141.9, 141.5, 141.3, 138.4, 135.4, 130.7, 129.7, 129.0, 128.2, 127.9, 121.4, 119.6, 112.5, 14.8, 14.3; <sup>125</sup>Te NMR (158 MHz, CDCl<sub>3</sub>): δ 665.6. MS (ESI<sup>+</sup>): *m/z* = 531.0 [M + H]<sup>+</sup>; HRMS (ESI<sup>+</sup>): calcd. for C<sub>25</sub>H<sub>23</sub>BF<sub>2</sub>N<sub>2</sub>Te, 531.1062 [M + H]<sup>+</sup>, found, 531.1057 [M + H]<sup>+</sup>. FTIR (cm<sup>-1</sup>) 3055, 2918, 1544, 1506, 1308, 1196, 1148, 1086, 984, 740, 700.

### 2.5 The oxidized product (HCTeO) from the reaction of HCTe and NaOCl

NaOCl (0.3 mL, 12% dissolved in H<sub>2</sub>O) was added to the solution of HCTe (60 mg) in CH<sub>3</sub>OH (50 mL). The reaction mixture was stirred at room temperature for 30 min. The solvent was evaporated under reduced pressure and the crude product was purified by column chromatography (Ethyl acetate / CH<sub>3</sub>OH = 9 : 1) to give the compound HCTeO as a dark red powder. Yield: 40 mg. (65%); melting point, 165-166 °C. <sup>1</sup>H NMR (500 MHz, CDCl<sub>3</sub>): δ 8.09 (d, *J* = 7.5 Hz, 2H), 7.52 (td, *J* = 7.5, 1.0 Hz, 1H), 7.39 (td, *J* = 8.5, 1.0 Hz, 1H), 7.25 (s, 1H), 7.15-7.11 (m, 2H), 7.01 (t, *J* = 7.0 Hz, 2H), 5.98 (s, 2H), 2.53 (s, 6H), 1.35 (s, 6H); <sup>13</sup>C NMR (75 MHz, CDCl<sub>3</sub>) δ 157.1, 156.9, 143.8, 142.7, 137.9, 137.6, 137.3, 136.6, 131.1, 130.8, 130.5, 130.4, 130.2, 130.1, 129.0, 128.5, 122.2, 121.8, 14.5, 13.8. <sup>125</sup>Te NMR (158 MHz, CDCl<sub>3</sub>): δ 1113.6. MS (ESI<sup>+</sup>): *m/z* = 547.1 [M + H]<sup>+</sup>; HRMS (ESI<sup>+</sup>): Calcd. for C<sub>25</sub>H<sub>23</sub>BF<sub>2</sub>N<sub>2</sub>TeO, 547.1012 [M + H]<sup>+</sup>, found 547.1001 [M + H]<sup>+</sup>. FTIR (cm<sup>-1</sup>) 3042, 2965, 1542, 1514, 1423, 1315, 1194, 1156, 1085, 977, 743, 734, 700.

### 2.6 Cell culture for RAW264.7 Macrophages

The cell line RAW264.7 was provided by the Food Industry Research and Development Institute (Taiwan). RAW264.7 cells were cultured in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% fetal bovine serum (FBS) at 37 °C under an atmosphere of 5% CO<sub>2</sub>. Cells were plated on 18 mm glass coverslips and

1  
2  
3 allowed to adhere for 24 h.  
4  
5

## 6 **2.7 Cytotoxicity assay**

7 The methyl thiazolyl tetrazolium (MTT) assay was used to measure the cytotoxicity  
8 of **HCTe** in RAW264.7 cells. RAW264.7 cells were seeded into a 96-well cell-culture  
9 plate. Various concentrations (5, 10, 15, 20, 25  $\mu\text{M}$ ) of **HCTe** were added to the wells.  
10  
11

12 The cells were incubated at 37 °C under 5% CO<sub>2</sub> for 24 h. 10  $\mu\text{L}$  MTT (5 mg/mL) was  
13

14 added to each well and incubated at 37 °C under 5% CO<sub>2</sub> for 4 h. Remove the MTT  
15

16 solution and yellow precipitates (formazan) observed in plates were dissolved in 200  
17  $\mu\text{L}$  DMSO and 25  $\mu\text{L}$  Sorenson's glycine buffer (0.1 M glycine and 0.1 M NaCl).  
18 Multiskan GO microplate reader was used to measure the absorbance at 570 nm for  
19 each well. The viability of cells was calculated according to the following equation:  
20  
21  
22  
23

24  
25 Cell viability (%) = (mean of absorbance value of treatment group) / (mean of  
26 absorbance value of control group).  
27  
28

## 29 **2.8 Fluorescence imaging of Exogenous HCTe in Living Cells**

30 Experiments to assess the sensing ability of **HCTe** for exogenous HOCl were  
31 performed in 0.1 M phosphate-buffered saline (PBS) with NaOCl (10  $\mu\text{M}$ ). Treat the  
32 cells with 2  $\mu\text{L}$  of 10 mM **HCTe** (final concentration: 10  $\mu\text{M}$ ) dissolved in DMSO and  
33 incubated for 30 min at 37 °C. The treated cells were washed with 0.1 M PBS (2 mL  
34  $\times$  3) to remove remaining **HCTe**. DMEM (2 mL) was added to the cell culture, which  
35 was then treated with 10 mM solution of NaOCl (2  $\mu\text{L}$ ; final concentration: 10  $\mu\text{M}$ )  
36 dissolved in sterilized 0.1 M PBS (pH 7.4). The samples were incubated at 37 °C for  
37 10 min. The culture medium was removed, and the treated cells were washed with 0.1  
38 M PBS (2 mL  $\times$  3) before observation. Confocal fluorescence imaging of cells was  
39 performed with a Leica TCS SP5 X AOBS Confocal Fluorescence Microscope  
40 (Germany), and a 63x oil-immersion objective lens was used. The cells were excited  
41 with a white light laser at 488 nm, and emission was collected at 530  $\pm$ 10 nm.

## 2.10 Quantum chemical calculation

Quantum chemical calculations based on density functional theory (DFT) were carried out using a Gaussian 09 program. The optimized geometries and energy levels of frontier molecular orbitals were performed using the B3LYP functional and the 6-31G basis set.

## 3. Results and discussion

### 3.1 Synthesis of the probe HCTe

The synthesis of the probe **HCTe** is outlined in Scheme 1. 2-(Phenyltellanyl) benzaldehyde was first prepared from the reaction of biphenyl ditelluride with 2-formyl phenyl boronic acid in the presence of CuI and 2,2'-dipyridyl. Treatment of 2-(phenyltellanyl) benzaldehyde with 2,4-dimethylpyrrole in the presence of trifluoroacetic acid (TFA) under N<sub>2</sub> produces the corresponding dipyrromethane. The dipyrromethane is then oxidized with 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ) to produce the corresponding dipyrromethene, which is transformed into the BODIPY skeleton in the presence of BF<sub>3</sub>. The structures of **HCTe** and **HCTeO**, the product of the reaction of **HCTe** with HOCl, were confirmed using <sup>1</sup>H and <sup>13</sup>C NMR spectroscopy and mass spectrometry.

### 3.2 Fluorescent response of HCTe with HOCl

We tested the sensing performance of the probe **HCTe** towards various ROS and RNS species, including HOCl, •OH, H<sub>2</sub>O<sub>2</sub>, <sup>1</sup>O<sub>2</sub>, NO<sub>2</sub><sup>-</sup>, NO<sub>3</sub><sup>-</sup>, NO, ONOO<sup>-</sup>, O<sub>2</sub>, and *t*-BuOOH, in a phosphate-buffered saline (PBS) solution. We found that strong green fluorescence only occurred upon addition of HOCl to a solution containing **HCTe**; other ROS and RNS produced no change in fluorescence (Fig. 1). Quantitative **HCTe** fluorescence was observed in the presence of several ROS and RNS that were tested, however, HOCl was the only reactive species that enhanced the fluorescence significantly. To study the influence of other ROS/RNS on the reaction of **HCTe** with HOCl, competitive experiments were performed with other ROS/RNS (100 μM) in the presence of NaOCl (20 μM).

In Fig. 2, the fluorescence enhancement caused by mixing NaOCl with most ROS/RNS was similar to that caused by NaOCl alone. When NaOCl was mixed with H<sub>2</sub>O<sub>2</sub>, the fluorescence intensity was lower. NaOCl reacts with H<sub>2</sub>O<sub>2</sub> to produce <sup>1</sup>O<sub>2</sub>, which does not respond to the **HCTe** probe. Due to the consumption of NaOCl by H<sub>2</sub>O<sub>2</sub>, a lower fluorescence intensity was observed in the presence of NaOCl and H<sub>2</sub>O<sub>2</sub>.<sup>28</sup> To further evaluate the selectivity of the **HCTe** probe towards HOCl, 15 different metal ions (Ag<sup>+</sup>, Al<sup>3+</sup>, Ca<sup>2+</sup>, Cd<sup>2+</sup>, Co<sup>2+</sup>, Cr<sup>3+</sup>, Cu<sup>2+</sup>, Fe<sup>2+</sup>, Fe<sup>3+</sup>, Hg<sup>2+</sup>, Mg<sup>2+</sup>,

1  
2  
3  $\text{Mn}^{2+}$ ,  $\text{Ni}^{2+}$ ,  $\text{Pb}^{2+}$ ,  $\text{Zn}^{2+}$ ) and 10 different anions ( $\text{Br}^-$ ,  $\text{CH}_3\text{COO}^-$ ,  $\text{CN}^-$ ,  $\text{F}^-$ ,  $\text{HSO}_4^-$ ,  
4  $\text{HPO}_4^{2-}$ ,  $\text{H}_2\text{PO}_4^-$ ,  $\text{I}^-$ ,  $\text{OH}^-$ ,  $\text{SCN}^-$ ) were tested. None of the ions tested produced a  
5 noticeable change in fluorescence intensity (Figure S17 and Figure S18 in the  
6 supporting information), indicating no response toward the **HCTe** probe. These results  
7 suggest that **HCTe** may respond to HOCl with low interference.  
8

9  
10 The reaction of **HCTe** with HOCl is fast; addition of NaOCl(aq) to a solution  
11 containing **HCTe** results in an immediate, strong increase in fluorescence intensity  
12 (see Figure S19 in the supporting information). During the titration of HOCl with  
13 **HCTe**, a new emission band appeared at 531 nm (Fig. 3). The emission intensity  
14 reached its maximum after the addition of one equivalent of HOCl. The quantum  
15 yield of the oxidized form, **HCTeO**, was  $\Phi = 0.75$ , which is 82-fold greater than that of  
16 **HCTe** (0.009). The structure of **HCTeO** was confirmed by  $^1\text{H}$  NMR,  $^{13}\text{C}$  NMR, and  
17 MS spectrometry. We observed a good linear correlation between fluorescence  
18 intensity and HOCl concentration over the range of 0–10  $\mu\text{M}$ , and found that **HCTe**  
19 has a detection limit of 41.3 nM (Figure S20 in the Supporting Information),  
20 indicating that it is sufficiently sensitive for the detection of HOCl in living cells.  
21

22 The HOCl-detection mechanism was determined by the density functional theory  
23 (DFT) calculation. As shown in Scheme 2, the highest occupied molecular orbital  
24 (HOMO) of the diphenyl telluride moiety (electron donor) is close to that of the  
25 fluorophore BODIPY (electron acceptor); the HOMO energy level (–5.45 eV) of the  
26 diphenyl telluride moiety is higher than that of BODIPY (–5.57 eV). Consequently,  
27 when the BODIPY moiety is excited by light, the electron transfer from the diphenyl  
28 telluride moiety to the BODIPY moiety is energetically allowed. Hence, the BODIPY  
29 fluorescence is quenched by the PET process ( $\Phi < 0.01$ ). In contrast, upon the  
30 oxidation of **HCTe** by HOCl, the HOMO energy level of the diphenyl telluroxide  
31 moiety (–6.29 eV) is below that of BODIPY. Thus, the PET process is avoided and  
32 the fluorescence of BODIPY is restored.<sup>30</sup>  
33

34 An experiment was conducted to determine the pH-dependence of **HCTe**, to  
35 establish a suitable pH range for HOCl sensing. Figure 4a shows that the emission  
36 intensities of **HCTe** are very low at a pH range of 4 – 10. After the addition of one  
37 equivalent of HOCl, the emission intensity at 531 nm increases significantly at a pH  
38 range of 5.5 – 8.0, which means that the probe could be used under these  
39 physiological conditions. When the pH exceeded 8.0, the emission intensity dropped  
40 slightly. This is because the  $\text{p}K_a$  of HOCl is 7.6 and hypochlorite ( $\text{ClO}^-$ ), which is  
41 dominant at  $\text{pH} > 8$ , has slightly poor reactivity with **HCTe**. The reducing agent  
42 glutathione (GSH) was used to determine the ability of **HCTeO** to be reduced to its  
43 original state. Figure 4b shows the reaction of the oxidized product **HCTeO** with  
44 GSH. A remarkable decrease in fluorescence was observed after the addition of GSH.

2  
3 This observation indicates the reversibility of **HCTe**, which can be used to monitor  
4 the dynamic changes in the HOCl present in living cells.

### 6 **3.3 Bioimaging of HCTe**

7 The potential of the probe **HCTe** for imaging HOCl in living cells was also  
8 investigated. RAW264.7 macrophages were used as a model cell line because  
9 macrophages are known to generate ROS and RNS in the immune system. An MTT  
10 assay was conducted with a RAW264.7 cell line to evaluate the cytotoxicity of **HCTe**.  
11 The cellular viability was estimated to be greater than 80% after 24 h, which indicates  
12 that **HCTe** (<25  $\mu$ M) has low cytotoxicity (see Figure S21 in the supporting  
13 information). Images of cells were obtained using confocal fluorescence microscopy.  
14 No fluorescence was observed for RAW264.7 cells that were incubated with 10  $\mu$ M  
15 **HCTe** (Fig. 5a). After treatment with NaOCl, bright green fluorescence was observed  
16 in the RAW264.7 cells (Fig. 5b). The overlay of fluorescence and bright-field images  
17 revealed that the fluorescence signals were localized in the intracellular area,  
18 indicating a subcellular distribution of HOCl and good cell-membrane permeability of  
19 **HCTe**. Further addition of GSH (200  $\mu$ M) in the culture medium caused the  
20 intracellular fluorescence in RAW264.7 cells to disappear (Figure 5c). This indicates  
21 that the oxidized probe (**HCTeO**) was reduced to the nonfluorescent probe (**HCTe**) by  
22 GSH.  
23

24 Furthermore, **HCTe** was used to detect PMA-induced endogenous HOCl  
25 production in RAW264.7 cells. Phorbol myristate acetate (PMA) activates the  
26 generation of ROS and RNS, including HOCl, in macrophage cells.<sup>31,32</sup> After  
27 stimulation with PMA (25 ng/mL) for 2 h in the presence of **HCTe**, strong green  
28 fluorescence was observed in the RAW264.7 cells (Fig. 6a). These results  
29 demonstrate that **HCTe** can enable the visualization of PMA-induced endogenous  
30 HOCl production in macrophages. When the MPO inhibitor 4-aminobenzoic acid  
31 hydrazide (ABAH, 100  $\mu$ M) was added to macrophage cells with PMA (25ng/mL), no  
32 fluorescence enhancement was observed. These results demonstrate that the presence  
33 of HOCl results in significant fluorescence enhancement in cells, whereas the  
34 fluorescence enhancement produced by other ROS and RNS is negligible.  
35

### 47 **4. Conclusion**

48 In summary, we have developed a BODIPY-based green fluorescent probe, **HCTe**,  
49 which displays a rapid, highly selective, and sensitive response to HOCl over other  
50 reactive species. This system utilizes the HOCl-promoted oxidation of diphenyl  
51 telluride to respond to the amount of HOCl. **HCTe** is rapidly oxidized by HOCl with  
52 an increase in emission. Confocal fluorescence microscopy imaging using RAW264.7  
53 cells showed that the probe **HCTe** could be used to evaluate the role of HOCl in  
54 biological systems
