## Abstract

The preparation of lauryl methacrylate (LMA) monolithic column for CEC by reversible addition-fragmentation chain transfer polymerization has been investigated. The *s,s*-2 (α, α-methyl-α"-acetic acid) 3-thiocarbonate (TTC1) was synthesized and added into the LMA monolithic column preparation as a chain transfer agent. At the same time, the preparation was compared with LMA -based monolith columns thermally polymerized without TTC1. The SEM and pore size measure showed that reversible addition-fragmentation chain transfer polymerization had more uniform polymer particle pore size, relatively narrower pore size distribution and larger surface area. The two kinds of monoliths had median pore diameters comprised 703 nm and 950 nm with pore volume of 13.22 cm<sup>3</sup>/g and 8.31 cm<sup>3</sup>/g, respectively. The influences of TTC1 amount and porogenic solvent composition on the physical and electrochromatographic properties of the LMA-based monolithic columns were also evaluated by capillary electrochromatography (CEC). Under the optimum conditions, H<sub>min</sub> value of 7.39 μm for naphthalene was achieved. The relative standard deviations (RSDs) of column-to-column (n=9), run-to-run (n=5) and day-to-day (n=3) reproducibility were lower than 4.8 %.

## 1 Introduction

Monolithic materials have been widely studied as stationary phase in high

1  
2  
3  
4 -performance liquid chromatography (HPLC) and capillary electrochromatography  
5  
6 (CEC) since the introduction of these materials in the early 1990s by Svec and  
7  
8 Frechet.<sup>1, 2</sup> In recent years, the development of the monolithic column has attracted  
9  
10 great attention in the field of micro-separation.<sup>3, 4</sup> The organic polymer monolith has  
11  
12 advantages, such as chemical stability and easy preparation with different monomers,  
13  
14 which has shown considerable application potential to the analytical field.<sup>5-7</sup> The  
15  
16 methacrylate monolithic column is a type of organic polymer monolith, which is  
17  
18 usually prepared through in situ polymerization of a mixture composed of functional  
19  
20 monomers, cross linkers, initiators and porogenic solvents.<sup>8-13</sup> Currently, many  
21  
22 technologies are applied to the monolithic columns preparation. The traditional free  
23  
24 -radical polymerization is one of common approaches to the monolithic columns  
25  
26 preparation.<sup>14-16</sup> As we know, the traditional free-radical polymerization reaction  
27  
28 could not easily control the polymerization rate and phase separation in  
29  
30 polymer-based monolithic column fabrication. These drawbacks could cause a large  
31  
32 variation in polymer molecular weight and the formation of a heterogeneous polymer  
33  
34 structure.<sup>17</sup> Therefore, it is important that a novel method is applied to create a more  
35  
36 uniform polymer in the process of the polymerization reaction.  
37  
38  
39  
40  
41  
42  
43  
44  
45

46 Living radical polymerization has been widely used for the commercial  
47  
48 production of high molar mass polymers.<sup>18</sup> The emergence of techniques for  
49  
50 implementing reversible deactivation radical polymerization serves to impart living  
51  
52 characteristics to the process and has provided a new set of tools for polymer chemists  
53  
54 that allow control over the polymerization process whilst retaining much of the  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 versatility of conventional radical polymerization.<sup>19</sup> Living radical polymerization  
5  
6 methods could be potential alternatives to overcome some of the above mentioned  
7  
8 drawbacks of the traditional free-radical polymerization reaction. The living radical  
9  
10 methods were proven to be a versatile and robust approach to preparing well-defined  
11  
12 organic polymers.<sup>20</sup> The termination and controlled reaction was established by an  
13  
14 equilibration between active and dormant species in the controlled/living radical  
15  
16 polymerization. The polymerization techniques have attracted attention, including  
17  
18 nitroxidemediated polymerization (NMP), atom transfer radical polymerization  
19  
20 (ATRP) and reversible addition-fragmentation chain transfer (RAFT).<sup>21-23</sup>  
21  
22  
23  
24

25  
26 RAFT polymerization is a promising living radical method for synthesizing  
27  
28 well-defined graft polymers.<sup>24, 25</sup> The RAFT polymerization has more advantages than  
29  
30 other living radical polymerization techniques, including the ability to polymerize in  
31  
32 the controlled manner of a wide range of monomers and the relatively easy reaction  
33  
34 conditions.<sup>26, 27</sup> Importantly, the RAFT polymerization process allows linear increases  
35  
36 in molar mass, therefore, the majority of the growing block polymers reaches the  
37  
38 point of becoming incompatible in the polymerizing monomer medium and  
39  
40 microphase separation over a small time interval, thereby resulting in a homogeneous  
41  
42 cross-linked, mechanically robust and nanostructured composite.<sup>28</sup> Nowadays, some  
43  
44 reports have showed that the RAFT techniques have been used to prepare monolithic  
45  
46 columns.<sup>29, 30</sup>  
47  
48  
49  
50  
51  
52

53  
54 In this study, TTC1 was initially prepared as a chain transfer agent and the TTC1  
55  
56 was then added into the LMA-based monolithic column preparation for CEC using 2,  
57  
58  
59  
60

1  
2  
3  
4 2-azobisisobutyronitrile (AIBN) as thermal initiator. The influence of the porogenic  
5  
6 solvent composition on the morphological properties and electrochromatographic  
7  
8 behaviors of the prepared monoliths were evaluated by CEC. The TTC1 amount was  
9  
10 also investigated in the preparation process. The benzene and benzene homologues  
11  
12 were investigated to determine the column efficiency of the prepared monolithic  
13  
14 column. Compared to the preparation of LMA monoliths thermally initiated using  
15  
16 AIBN without TTC1, the prepared monolithic column showed higher column  
17  
18 efficiency and separation performance.  
19

27  
28 2-Acrylamide-2-methylpropanesulfonic acid (AMPS), ethylene dimethacrylate  
29  
30 (EDMA), 3-(trimethoxysilyl)propylmethacrylate ( $\gamma$ -MAPS), LMA, cyclohexanol and  
31  
32 1, 4-butanediol were purchased from Alfa Aesar (Alfa Aesar, China). AIBN,  
33  
34 acetonitrile (ACN), concentrated hydrochloric acid, sodium dihydrogen phosphate  
35  
36 ( $\text{NaH}_2\text{PO}_4$ ), trichloromethane and methanol (HPLC grade) were obtained from  
37  
38 Sinopharm Chemical Reagents (Shanghai, China). Petroleum ether, acetone, carbon  
39  
40 disulfide and tetrabutyl ammonium bromide (TBAB) were supplied by Chen Hua  
41  
42 Chemical Reagent (Tianjin, China). Thiourea, benzene, methylbenzene, ethylbenzene  
43  
44 and naphthalene were supplied by Sinopharm Chemical Reagents (Shanghai, China).  
45  
46  
47  
48  
49 A fused-silica capillary of 100  $\mu\text{m}$  *id* was obtained from Yongnian Optic Fiber Plant  
50  
51 (HeBei, China). Water was purified by a Milli-Q purification system (Millipore,  
52  
53  
54  
55  
56  
57  
58  
59  
60 Bedford, MA).

## 2.2 Apparatus

CEC experiments were performed on a HP<sup>3D</sup> CE instrument (Agilent Technologies, Waldbronn, Germany) system equipped with a diode array detector (DAD), and connected to an external nitrogen pressure source. The cassette holding the capillary column was kept at 25 °C. Data acquisition and analysis were performed with Agilent CE ChemStation. SEM photographs of monolithic materials were taken with a scanning electron microscope (Philips, Eindhoven, Netherlands). FT-IR spectra were recorded on a Nicolet 360 smart (Nicolet, USA). Elemental analysis was measured by Vario EL (Elementar). AutoPore IV 9520 was used to measure the pore size (micromeritics, USA).

## 2.3 Pre-treatment of the silica capillary

According to the literature,<sup>14</sup> prior to the preparation of the monolithic column, the silica capillary was treated for vinyl group modification by the following procedure. The capillary was rinsed with 0.1 mol/L NaOH for 2 h, water for 30 min, 0.1 mol/L HCl for 2 h and water for another 30 min, respectively. Subsequently flushing with methanol for 60 min, it was dried by nitrogen gas.  $\gamma$ -MAPS was dissolved in methanol (50%, v/v) and pumped into capillary by a syringe, then the capillary was sealed with rubber. The reaction was performed at 60 °C for 24 h in a water bath. The capillary was washed with methanol for 30 min and dried under nitrogen. Thus, the inner wall of the capillary was modified by a layer of  $\gamma$ -MAPS, which could supply sufficient sites for subsequent attachment of column to the wall during the following preparation.

## 2.4 Preparation of chain transfer agent

According to the literature,<sup>31</sup> TTC1 was synthesized by following procedure: carbon disulfide (2.74 g), acetone (5.23 g), chloroform (10.75 g), TBAB (0.229 g) and petroleum ether (20 mL) were added into a 100 mL three-necked flask with the dropping funnel and condensing tube under nitrogen. Sodium hydroxide (50%) (201.6 g) was added drop wise over 90 min; the stirring reaction was kept below 25 °C for over 12 hours. When the reaction was completed, 90 mL of water was added to dissolve solid and 30 mL concentrated hydrochloric acid (6 mol/L) was used to adjust the pH < 4. The stirring reaction was kept for 30 min under nitrogen again. The yellow solid was obtained after filtration with plenty of washing and recrystallized with ethanol. The reaction route is showed in Fig. 1.

## 2.5 Preparation of LMA-based monolithic columns

The polymerization mixtures consisting of suitable amounts of LMA (240 µL), EDMA (160 µL) as monomers, AMPS (2 mg) supporting EOF, a ternary mixture composed of water (20 µL), cyclohexanol (440 µL), 1, 4-butanediol (140 µL) as porogenic solvent and AIBN (4 mg) containing different amount of TTC1 as initiator were ultrasonicated for 10 min to obtain a homogeneous solution and then purged with nitrogen for 10 min. The deaerated mixture was filled into the modified capillary (33 cm) to a total length of 25 cm by syringe injection. After both ends sealed with rubber stoppers, the capillary was submerged into a bath of water at 60 °C for 20 h. The resulted column was flushed with methanol for 2 h using a HPLC pump to remove pore-forming solvent and unreacted monomers. The detection window was

1  
2  
3  
4 burned with a flame torch at the adjacent to the monolithic material.  
5

## 6 **2.6 Evaluation of LMA-based monolithic column**

7

8  
9 Prior to experiment, phosphate buffers (pH 9.2) were prepared by adding sodium  
10 hydroxide to sodium dihydrogen phosphate. All buffers were filtered with a 0.22  $\mu\text{m}$   
11 membrane filter. Standard solutions and running buffers were degassed by  
12 ultrasonication for 10 min. Each monolithic column was placed in the instrument and  
13 equilibrated with the mobile phase by applying a stepwise increase in voltage up to 25  
14 kV and 8 bar pressure at the both ends of the column, until a stable baseline was  
15 observed. The separations were performed at 20 kV with the column kept at 25 °C. A  
16 test mixture containing thiourea, phenol, benzene, methyl benzene and naphthalene  
17 was used to evaluate the CEC performance of columns using a mobile phase  
18 consisting of 65 % (ACN w/w), 10 mM buffer at pH 9.2. The sample solution was  
19 injected electrokinetically at 10 kV for 6 s. Detection was performed at 214 nm.

## 36 **3 Result and discussion**

37

### 38 **3.1 Structural characterization of the TTC1**

39

40  
41 The chemical structure of TTC1 was confirmed by FT-IR spectroscopy (Fig. 2).  
42 The peak at 3423.84  $\text{cm}^{-1}$  was evident as hydroxyl group and the peak at 1703.52  $\text{cm}^{-1}$   
43 was carbonyl group. In addition, the peaks at 1286.32  $\text{cm}^{-1}$  and 1066.06  $\text{cm}^{-1}$   
44 confirmed the presence of carbon-sulfur bond (C-S-C) and carbon-sulfur double bond  
45 (C=S), respectively. Other peaks were also labeled in Fig. 2. In fact, the FT-IR data  
46 were very similar to the data of TTC1 in the literature.<sup>32</sup> The chemical structure of  
47 TTC1 was confirmed with C: 31.220; H: 4.282; S: 26.206 and O: 17.471 by elemental

analysis.

### 3.2 Mechanism of Polymerization

The mechanism of RAFT polymerization was involved in a reversible addition fragmentation sequence. The transfer of S=C(S)-S-moiety between active and dormant chains serves to maintain the living character of the polymerization (Fig. 3). The S=C(S)-S-moiety was confirmed by infrared spectrogram for evidence of this mechanism. Fig. 3 shows that the S=C(S)-S-end group was retained in the polymeric product. TTC1 was doped into the RAFT polymerization as a chain transfer agent. The effectiveness of TTC1 was attributed to its high transfer constants which could ensure a rapid rate of exchange between dormant and living chains. The S=C(S)-S-end group of TTC1 was crucial to the success of the RAFT process. It not only could activate the C=S double bond toward radical addition, but also was a good free radical leaving group.

### 3.3 Optimization of preparation for monolithic columns

#### 3.3.1 Effect of porogenic solvent composition

As we know, the ratio of porogenic solvent composition could not only affect the monolithic column structure, but also relate to performance of monolithic columns in the process of preparation. Therefore, it was necessary to optimize the porogenic solvent composition in the process of preparation for the LMA-based monolithic columns. Based on our previous experiment, firstly, the polymerization temperature was selected at 60 °C, then 4.0 mg AIBN (1.0 wt % with respect to the monomers) and 2.0 mg AMPS (0.5 wt % with respect to the monomers) were selected. Secondly,

1  
2  
3  
4 the water content (2.0 %, v/v) was fixed and the proportion of monomers to  
5  
6 pore-forming solvents was 40:60 (v/v). Then, a series of LMA-based monolithic  
7  
8 columns were prepared by changing the percentage of 1, 4-butanediol in the  
9  
10 polymerization mixture. The different compositions were listed in Table 1. Table 1  
11  
12 indicates that with the increase of the 1, 4-butanediol content, the progressive rise in  
13  
14 the flow velocity was obtained and the retention factor  $k_{naphthalene}$  calculated from the  
15  
16 equation  $k = (t_r - t_0)/t_0$  was reduced, where  $t_r$  and  $t_0$  are the retention time of naphthalene  
17  
18 and thiourea. The results were in agreement with the reported literature.<sup>33</sup> It was a  
19  
20 reasonable explanation that the polarity of the polymerization mixture and pore size  
21  
22 increased with an increase of 1, 4-butanediol percentage. The column efficiency was  
23  
24 also examined by measuring the minimum plate height ( $H_{min}$ ) of naphthalene. The  
25  
26 experimental result also showed that the monolithic column with liquid pump flushing  
27  
28 was difficult with 1, 4-butanediol less than 12% (v/v). At the same time, we found  
29  
30 that when the content of 1, 4-butanediol was 14.0%,  $H_{min}$  achieved the best level in the  
31  
32 CEC experiment. It was a reasonable explanation that the pore size increased  
33  
34 gradually with an increase of 1, 4-butanediol percentage. The behavior has been  
35  
36 reported by other literatures.<sup>34</sup>

### 3.3.2 Effect of TTC1 amount

37  
38  
39 As we know, the polymerization reaction rate and uniformity play important roles  
40  
41 for the homogeneities and sizes of pores and globules in the preparation of monolithic  
42  
43 column. Therefore, the TTC1 was added into the polymerization reaction. Different  
44  
45 proportions of TCC1 and AIBN were investigated in our experiment. The initial  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 polymerization reaction was chosen as follows: the proportions of monomers to  
5  
6 pore-forming solvents were 40:60 (v/v), and the optimal content of 1, 4-butanediol  
7  
8 (14%, v/v) was found in the previous section. The TTC1 amount in the  
9  
10 polymerization mixture was optimized by varying its amount to compare the AIBN in  
11  
12 Table 2. The temperature was kept at 60 °C for 20 h. Table 2 shows different amounts  
13  
14 of TTC1 which is doped to the 1 wt% AIBN as initiator exhibited different  $H_{\min}$   
15  
16 values for naphthalene. With an increase of TTC1 amount in the polymerization  
17  
18 reaction, the  $H_{\min}$  values of naphthalene were clearly improved. However, when TTC1  
19  
20 amount was double to AIBN content, the  $H_{\min}$  values were stable. The retention  
21  
22 behavior was also examined along this series. The results showed that flow rates and  $k$   
23  
24 values had little changes with the increase of TTC1 amount in the polymerization  
25  
26 reaction.  
27  
28  
29  
30  
31  
32

### 34 **3.4 Evaluation of monolithic column**

#### 36 **3.4.1 Morphology and column efficiency**

37  
38  
39 In order to investigate the difference of the only AIBN and the AIBN containing  
40  
41 TTC1 as initiator, SEM pictures and CEC performance of monoliths have been  
42  
43 performed. SEM pictures of the optimal monolithic beds show a significant difference  
44  
45 (Fig. 4). Fig. 4B exhibits more uniform polymer pore particle size, relatively narrower  
46  
47 pore size distribution and larger surface area than that of Fig. 4A. The porous  
48  
49 properties of the rigid monolithic phases were further investigated using mercury  
50  
51 intrusion porosimetry. As shown on Fig.5, The two kinds of monoliths had a median  
52  
53 pore diameter comprised 703 nm and 950 nm with pore volume of 13.22 cm<sup>3</sup>/g and  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 8.31 cm<sup>3</sup>/g, respectively. The monolithic column using AIBN containing TTC1 as  
5  
6 initiator had a very narrow size distribution. At the same time, under the same  
7  
8 separation conditions, the monolithic column using AIBN containing TTC1 as  
9  
10 initiator has better efficiency values. The behaviors indicate the presence of higher  
11  
12 number of microspores and larger surface area in the globule structure of the  
13  
14 monolithic columns thermally polymerized with AIBN containing TTC1 as initiator.  
15  
16 The Fig.6 indicates that two type monolithic columns have different column efficiency,  
17  
18 it may conclude that LMA-based monolithic columns thermally initiated using AIBN  
19  
20 containing TTC1 have advantages over those using the only AIBN as initiator.  
21  
22  
23  
24  
25

### 26 **3.4.2 Monolithic column repeatability and stability**

27  
28  
29 In order to evaluate repeatability and stability of the resulting columns, the  
30  
31 monolithic columns were prepared under the optimal polymerization reaction  
32  
33 conditions, and several electrochromatographic parameters were determined by CEC.  
34  
35 The reproducibility of column production was assessed by the relative standard  
36  
37 deviation (RSD, %) from column-to-column (n = 3) and batch-to-batch (n = 3) using  
38  
39 thiourea and benzene homologous series as a model system. The results are listed in  
40  
41 Table 3. As seen from Table 3, satisfactory reproducibilities were obtained for all  
42  
43 tested parameters. Run-to-Run repeatability (n = 5) and column-to-column (n = 9)  
44  
45 stability were achieved with RSDs<1.7% and RSDs<4.0% in the studied  
46  
47 electrochromatographic parameters, respectively. The electrochromatographic  
48  
49 behaviors of the prepared monolithic column using AIBN containing TTC1 was  
50  
51 consistent with those by conventional preparation method for column.

#### 4 Concluding remarks

As a chain transfer agent, TTC1 was synthesized and added into the polymerization reaction of LMA-based monolithic columns. The influences of TTC1 amount and porogenic solvent composition were investigated. The experimental results showed that the possibility of a fine-tuning of porous and electrochromatographic properties of monolithic columns were achieved by adjusting the 1, 4-butanediol content and TTC1 amount. Under optimum conditions of preparation for monolithic columns,  $H_{\min}$  value of 7.39  $\mu\text{m}$  for naphthalene was achieved. The produced monolithic columns also exhibited good repeatability and stability. A comparison of the CEC performance with LMA-based columns thermally polymerized using AIBN without TTC1 as initiator was also carried out. The LMA-based monolithic columns initiated with AIBN containing TTC1 had better  $H_{\min}$  value and much higher permeability than those polymerized using AIBN without TTC1 as initiator. Thus, the TTC1 added to the polymerization reaction could offer an attractive way to prepare the monolithic columns.

The project was financially supported by Jiangxi Provincial Department of Education Science and Technology Project (GJJ12702), PhD research start-up capital of Shangrao Normal College (001031). The authors are grateful to the Food Security Analysis and Detection (Fuzhou University), Ministry of Education Key Laboratory and Agilent Technologies. The authors have declared no conflict of interest.
