1 **Abstract**

2 Doxorubicin is a highly efficient antitumor drug, but it can induce toxicity, largely
3 affecting people's life. Metabolomics technology, a part of systems biology, can offer
4 information on the change on metabolic profiles of biofluids upon drug
5 administration. Meanwhile, the plasma metabolomics study on doxorubicin toxicity
6 using liquid chromatography-mass spectrometry technology is not very clear. In this
7 study, plasma metabolomics approach using rapid resolution liquid chromatography
8 coupled with quadruple-time-of-flight mass spectrometry technology was used to
9 investigate the toxic mechanism of doxorubicin from metabolic view. The
10 biochemical analysis and histopathological examination result showed that toxicity
11 model can be built by intraperitoneal injection of doxorubicin with the dose of 15
12 mg/kg in male Wistar rats. Metabolomics results revealed fifteen biomarkers were
13 changed due to doxorubicin-induced toxicity. Besides, arachidonic acid metabolism,
14 valine, leucine and isoleucine biosynthesis, sphingolipid metabolism,
15 glycerophospholipid metabolism and primary bile acid biosynthesis were mainly
16 responsible for the toxicity of doxorubicin. The changed metabolites and interrupted
17 pathways found in this study are meaningful and the result can lay the foundation for
18 further research on the toxicity mechanism of doxorubicin.

1 Introduction

2 Doxorubicin (DOX), an anthracycline antibiotic and a derivative of *Streptomyces*
3 bacteria, is a highly efficient antitumor drug, but its organotoxic potential (cardio-,
4 hepato-, and nephrotoxicity) limits its clinical use. DOX is mainly metabolised in the
5 liver, with doxorubicinol, doxorubicinone, and 7-deoxydoxorubicinone as its major
6 metabolites.¹⁻² Some mechanism of DOX-induced toxicity has been proposed,
7 including the inhibition of nucleic acid and protein synthesis,³ the generation of free
8 radical,⁴ induction of apoptosis,⁵ but the exact metabolic causal mechanism of
9 toxicity has not yet been fully elucidated. Thus, a simple and accurate method for
10 revealing the mechanism of DOX is urgently needed.

11 Metabolomics, is now recognised as a widely used technique to advance the
12 toxicology, disease diagnosis, and therapeutic efficacy.^{6,7} Metabolomics aims to gain
13 global information of metabolite profile in systems including cell, tissue and
14 organism under a specific condition, such as pathophysiological stimuli, drug
15 administration, environment, or other factors.⁷⁻¹⁰ Nowadays, metabolomics has
16 become a new and powerful method in the study of mechanism of drug-induced
17 toxicity. In addition, metabolomics pays more attention to small and low weight
18 molecules. It is these metabolites that are the final product in biological metabolic
19 pathway and play an important role in metabolism.¹¹⁻¹³ Therefore, the changed level
20 of specific metabolites in biofluid which can be identified by metabolomics
21 technology can reflect physiological state in some extent and can reveal the

1
2
3
4 1 mechanism of toxicity in metabolic level.
5
6

7 2 Data acquisition is firstly performed to do further data analysis and find useful
8
9
10 3 information in metabolomics study. Nowadays, mass spectrum analytical method is
11
12 4 widely used to do data acquisition in metabolomics study. Because biofluid is
13
14
15 5 complex and mixture sample, mass detector is usually coupled with a separation
16
17
18 6 chromatography system, including gas chromatography (GC) and liquid
19
20
21 7 chromatography (LC).¹⁴⁻¹⁶ When analyzed with gas chromatography-mass
22
23
24 8 spectrometry (GC-MS) technology, sample must be volatile or made volatile by
25
26
27 9 derivatization. Liquid chromatography-mass spectrometry (LC-MS) does not have
28
29
30 10 this problem and the sample preparation is relatively simple. What's more, rapid
31
32
33 11 resolution liquid chromatography (RRLC) coupled with quadruple-time-of-flight
34
35
36 12 mass spectrometry (Q-TOF-MS) has the advantage of high sensitivity and high
37
38
39 13 resolution, becoming a powerful technology in data acquisition of metabolomics.

40 14 Until now, few metabolomics study had been applied to find the toxic effect of
41
42
43 15 doxorubicin on heart issue¹⁷ or cell *in vitro*¹⁸ using GC-MS technology or nuclear
44
45
46 16 magnetic resonance (NMR) technology. Besides, Wang *et al* adopted metabolomics
47
48
49 17 technology coupled with LC-MS analysis to reveal the profiling of rat urinary
50
51
52 18 metabolites interrupted by doxorubicin administration, finding six small weight
53
54
55 19 molecular metabolites responsible for doxorubicin toxicity in urine.¹⁹ It is a fact that
56
57
58 20 the metabolites in different kinds of biofluid have some distinction, meanwhile, the
59
60 21 endogenous metabolites detected by different technology (LC-MS, GC-MS or NMR)

1 also varied. Though some study had been performed to observe the toxic
2 characteristic of doxorubicin, the plasma metabolomics investigation on doxorubicin
3 toxicity using LC-MS technology is not very clear and still need to be further studied.
4 In this study, metabolomics approach based on rapid-resolution liquid
5 chromatography coupled with quadrupole time-of-flight mass spectrometry
6 (RRLC-Q-TOF-MS) technique was applied to investigate the effect of doxorubicin
7 on plasma metabolites, determine the possible interrupted pathways related to
8 doxorubicin-induced toxicity, aim for reveal the toxic mechanism of doxorubicin and
9 provide important information for further research on doxorubicin toxicity.

10 **Experimental**

11 **Reagents and materials**

12 Doxorubicin was obtained from Shenzhen Main Luck Pharmaceuticals Inc.
13 (Shenzhen, China). The assay kits were obtained from the Biosino Bio-technology
14 and Science Inc. (Beijing, China). High performance liquid chromatography
15 (HPLC)-grade acetonitrile was purchased from Oceanpak (Goteborg, Sweden).
16 HPLC-grade formic acid was purchased from ROE (USA).

17 **Animal experiment**

18 This study was approved by the Animal Ethics Committee of Tianjin University of
19 Traditional Chinese Medicine under permit number TCM-2011-065-F02. Male
20 Wistar rats weighing 200 g to 220 g were kept in the same room at a temperature of
21 25 ± 1 °C and at humidity of $50 \pm 5\%$, on a 12 h/12 h light/dark cycle. Before the

1
2
3
4 1 experiment, the rats were acclimated with free access to food and water for one week.
5
6
7 2 The rats were randomly divided into 2 groups of 12 rats each: DOX group and
8
9
10 3 control group. DOX was first dissolved in normal saline (0.9% w/v), and then the
11
12
13 4 rats in DOX group were injected doxorubicin intraperitoneally with a single dose of
14
15
16 5 15 mg/kg. The control rats were injected intraperitoneally with 1 ml saline so that
17
18
19 6 they were exposed to the same stress. At 24 h after administration, blood samples
20
21
22 7 and liver, kidney, and heart tissues were collected. All of the procedures described
23
24
25 8 above were conducted in accordance with the Chinese national legislation and local
26
27
28 9 guidelines.

29 **Clinical chemistry and histopathology**

30
31
32 11 The serum samples were analyzed with an auto-chemistry analyzer (BIOSINO, Ltd.)
33
34
35 12 for aspartate aminotransferase (AST), creatine kinase (CK), and blood urea nitrogen
36
37
38 13 (BUN). The fixed tissues were processed, embedded in paraffin wax, cut (5 μ m
39
40
41 14 thickness), and stained with hematoxylin and eosin. Finally, the liver, kidney, and
42
43
44 15 heart tissues were observed for histopathological changes using a light microscope at
45
46
47 16 200 \times magnification.

48 **Metabolomics data acquisition**

49
50
51 18 Plasma metabolites profiling was performed by RRLC-Q-TOF-MS (Agilent, USA).
52
53
54 19 After plasma was thawed at room temperature, 300 μ L acetonitrile was added to 100
55
56
57 20 μ L of the plasma and ultrasonicated in cold water for 10 min, vortexed for one
58
59
60 21 minute, then centrifuged at 15, 000 rpm for 15 min. 10 μ L of supernatant was

1
2
3
4 1 injected onto ACQUITY UPLC HSS C₁₈ column (2.1 mm × 100 mm, 1.8 μm
5
6
7 2 particles; Waters) maintained at 40 °C at a flow rate of 0.3 ml/min. The gradient
8
9
10 3 mobile phase condition was composed of phase A (0.1% formic acid in water) and
11
12 4 phase B (0.1% formic acid in acetonitrile). The gradient started with 99% A, then at
13
14
15 5 0 min to 3 min, A: 99% to 48%; at 3 min to 7 min, A: 48% to 26%; at 7 min to 9 min,
16
17
18 6 A: 26% to 20%; at 9 min to 10 min, A: 20% to 10%; at 10 min to 12 min, A: 10% to
19
20
21 7 1%; at 12 min to 16 min, A: 1% to 1%; at 16 min to 17 min, A: 1% to 99%; at 17
22
23
24 8 min to 20 min, A: 99% to 99%. MS system was operated using the ESI⁺ mode and
25
26
27 9 the mass range was set at 50-1000 m/z in the full scan mode. The optimal capillary
28
29
30 10 voltage was set at 3.5 kV, and drying gas temperature was set at 325 °C, the drying
31
32
33 11 gas flow was set at 10 ml/min and desolvation gas flow rate was 600 l/h, nebulizer
34
35
36 12 pressure was 350 psi, the fragmentor voltage for MS was 175V and the collision
37
38
39 13 energy for MS/MS was set at 70V. All samples were maintained at 4 °C during
40
41
42 14 analysis. Before injecting samples collected in different groups, Quality control (QC)
43
44
45 15 sample, a mixture of plasma gained from each group, was first applied to detect the
46
47
48 16 instrument precision and stability. if the total chromatographic system was not stable,
49
50
51 17 the injection of plasma can not be permitted and the chromatographic acquisition
52
53
54 18 could start until the whole system was at a good and stable condition. Moreover, QC
55
56
57 19 samples were injected to test for the stability of samples and system during the
58
59
60 20 whole acquisition.

21 **Metabolomics data processing**

1
2
3
4 1 After data acquisition, a large amount of information was gained. To exclude useless
5
6
7 2 information, all the MS raw files was extracted by Agilent MassHunter Qualitative
8
9
10 3 Analysis B.04.00 software with noise elimination level 5, converting important and
11
12 4 useful information into CDF format. Automated peak detection, peak alignment, and
13
14
15 5 normalization were performed by Agilent MassHunter Mass Profiler software
16
17
18 6 (version 4.0). The data was processed by normalisation by sum (analogous to total
19
20
21 7 ion count normalization). The corresponding parameters were set as follows: Mass
22
23
24 8 tolerance (intercept 2.0 mDA, slope 5.0 ppm), Retention Time (RT) tolerance
25
26
27 9 (intercept 0.5 min, slope 0.5%), Result filters (min relative frequency 80% in at least
28
29
30 10 group), special mass excluded, neutral losses ignored, isotope peaks removed.
31
32 11 According to the former procedure, the data was processed and transformed to an
33
34
35 12 excel format, containing whole information of the Mass, RT, peak area of the
36
37
38 13 samples.

39
40
41 14 To find the changed metabolites, multivariate data analysis should be firstly
42
43
44 15 performed to select the potential biomarkers of doxorubicin-induced toxicity.
45
46
47 16 Multivariate data analysis was performed with SIMCA-P+ 12.0 software (Umetrics
48
49
50 17 AB, Umea, Sweden). The data was mean centered and scaled prior to data analysis.
51
52
53 18 We used pareto scaling in performing further analysis. Principal component analysis
54
55
56 19 (PCA), a widely used multivariate data analysis, was used to gain an overall insight
57
58
59 20 of samples from DOX group and control group. We can also remove outlier beyond
60
21 95% confidence level by PCA. Partial least squares-discriminant analysis (PLS-DA),

1
2
3
4 1 a supervised method, was subsequently applied to determine changed plasma
5
6
7 2 metabolites among control group and DOX group. The established model was
8
9
10 3 validated by cross validation and permutation tests.²⁰ The validation statistics, R^2
11
12 4 (cum) and Q^2 (cum), indicated the fitness and prediction of the model. These two
13
14
15 5 parameters were below 1 and can show a proper and good model when close to 1. In
16
17
18 6 this study, score plot was used to visualize the established model. In the score plot,
19
20
21 7 every point represented one sample and every sample included various variables.
22
23
24 8 The changed endogenous metabolites disturbed by drug administration were also
25
26
27 9 observed from the S-plot, loading plot and variable importance plot (VIP). In the
28
29
30 10 S-plot and loading plot, changed metabolites were always located far away from the
31
32
33 11 cluster. In this study, metabolites with $VIP > 1$ and variations far away from the
34
35
36 12 S-plot and the loading plot were firstly chosen as potential biomarkers. Then, an
37
38
39 13 independent sample t-test was performed on the metabolites with $VIP > 1$ using SPSS
40
41
42 14 17.0 software, and only significantly changed metabolites ($p < 0.05$) were
43
44
45 15 summarized for further study.

16 **Metabolite identification**

17
18 17 The significantly changed m/z value of the metabolites was determined, which was
19
20
21 18 the relatively accurate provided by the Q-TOF-MS analysis platform. Identification
22
23
24 19 of the candidate biomarkers was based on retention behavior, mass assignment, and
25
26
27 20 online database query. The accurate mass and structure information of candidate
28
29
30 21 metabolites were matched with those of metabolites obtained from HMDB

1 (www.hmdb.ca), METLIN (metlin.scripps.edu/) and KEGG (www.genome.jp/kegg/)
2 databases. Some biomarkers were identified based on their MS/MS fragment
3 information, which was supplied by RRLC-Q-TOF-MS analysis coupled with
4 available database information from MassBank (<http://www.massbank.jp/>). Besides,
5 other endogenesis were identified by comparing mass spectra and retention time with
6 the available reference standards.

7 **Disturbed metabolic pathways and metabolic network visualization**

8 In this study, MetPA (<http://metpa.metabolomics.ca/MetPA/faces/Home.jsp>) was
9 used to find the disturbed pathways related to doxorubicin toxicity. MetPA was a
10 web-based tool that combined the result from powerful pathway enrichment analysis
11 with the pathway topology analysis. MetPA can researchers identify the most
12 relevant pathways involved in the conditions under study. It had become an
13 important tool in metabolomics study.²¹ Besides, The selected corresponding
14 pathways were imported into Cytoscape software (<http://www.cytoscape.org/>) for
15 visualization of metabolomics result. These pathways were considered to have close
16 relationship with the mechanism of doxorubicin-induced toxicity.

17 **Results and discussion**

18 **Clinical chemistry and histopathological assessment**

19 Various clinical parameters were measured in plasma to monitor the toxic effect of
20 DOX. In the DOX group, the concentration of AST, BUN, and CK were significantly
21 increased in blood at 24 h after administration (Fig. 1). As shown in Fig. 2,

1 toxicity-related alterations including eosinophilic degeneration in the liver cell,
2 irregularly arranged cells and cytoplasmic condensation in the stripe region of heart.
3 The swelling of kidney tubules was also observed in the DOX group at 24 h after
4 administration. Combined clinical chemistry analysis with histopathological
5 examination, it can be concluded that single intraperitoneally injection of DOX with
6 the dose of 15 mg/kg actually caused liver, kidney, and heart injury in rats.

7 **Metabolic profiling analysis**

8 The typical total ion current (TIC) chromatograms of plasma (Fig. 3) in the control
9 and DOX group in positive mode were gained based on the RRLC-Q-TOF-MS
10 platform. About 4500 features were detected after MS data preprocessed. The
11 preprocessed metabolomics data was used to perform PCA, aiming to discover
12 principal components that accounted for the majority of the differences in the data.
13 In a PCA score plot, similar samples were grouped together and different samples
14 were dispersed.^{22,23} Fig. 4a showed distinctions among control group and DOX
15 group. The plasma samples in the DOX group were located far from those of the
16 control group, indicating that the plasma endogenous substances changed after
17 administration, which was concordant with our clinical chemistry analysis and
18 histopathological observations. PLS-DA was applied to determine the differences in
19 the metabolite profiles among different groups. The PLS-DA results was shown in
20 Fig. 4b, the rat plasma profiles showed changes due to DOX. In the S-plot and
21 loading plot, some metabolites in the plasma were distant from the cluster and thus

1 treated as potential biomarkers for further study (Fig. 4c and Fig. 4d).

2 The $R^2X(\text{cum})$, $R^2Y(\text{cum})$ and $Q^2(\text{cum})$ value of the established PLS-DA model
3 were 0.55, 0.986 and 0.961, respectively. The high value of Q^2 and R^2 indicated the
4 rationale of the model built in this study. What's more, the PLS-DA assessment was
5 validated by cross validation and permutation tests and the permutation statistics R^2
6 and Q^2 intercepts were 0.548 and -0.141, respectively. Besides, In the PLS-DA
7 model used for the selection of biomarkers, there were 153 variables with $VIP > 1$
8 which contributed to the separation of plasma endogenous metabolites between
9 control group and DOX group. Among these 153 variables, 96 variables exhibited a
10 significant change ($p < 0.05$), which will be performed to further biomarker
11 identification.

12 **Identification of potential biomarkers**

13 Multivariate statistical analysis facilitated the identification of biomarkers and the
14 m/z value of the significantly changed biomarkers were selected from a large amount
15 of plasma endogenous metabolites, which was the relatively accurate provided by
16 the Q-TOF-MS analysis platform. We searched the molecular of metabolites in
17 online database such as HMDB using available m/z value. The final identification of
18 biomarkers were based on MS/MS information, former reported research and
19 available commercial standard.

20 In this study, we chose 15 significantly changed metabolites in plasma among
21 control group and DOX group. Among these selected biomarkers, thirteen

1 metabolites were identified by their MS/MS information. To better understand this
2 identification, we took the ions at ($t_R = 9.56$ min, m/z 494.3236) as an example to be
3 described below. The molecular formula was supposed to be $C_{24}H_{48}NO_7P$ searched
4 by HMDB database using m/z 494.3236. In addition, the main fragment ions in
5 positive MS/MS spectrum were found at m/z 476.3, 184.0, 125.0 and 104.0, which
6 could be the ions formed by the $[M+H]^+$ of lost $-H_2O$, $-C_{19}H_{35}NO_2$ $-C_{22}H_{42}NO_3$ and
7 $-C_{20}H_{40}NO_4P$ respectively. Based on the MS/MS information, the metabolite was
8 finally identified as lysophosphatidylcholine (16:1) [LPC (16:1)]. Some biomarkers
9 were identified by their standards, such as valine and arachidonic acid. These two
10 biomarkers were identified by comparing mass spectra and retention time with the
11 available reference standards. Details of our analyses was shown in Table 1.

12 **Visualization of disturbed metabolic pathways**

13 The identified biomarkers responsible for DOX-induced toxicity played an
14 important role in specific metabolic pathways. Therefore, finding the disturbed
15 metabolic pathways can help us better understand the mechanism of DOX-induced
16 toxicity. In this study, the disturbed pathway was analyzed by MetPA. In MetPA
17 analysis, we selected the pathways with impact value above 0 as the affected
18 pathways. As shown in Fig. 5, arachidonic acid metabolism (a), valine, leucine and
19 isoleucine biosynthesis (b), sphingolipid metabolism (c), glycerophospholipid
20 metabolism (d) and primary bile acid biosynthesis (e) were disturbed in the rats of

1
2
3
4 1 DOX group. The visualization of identified biomarkers and corresponding pathways
5
6
7 2 can be seen in Fig. 6.
8

3 **Effects of doxorubicin toxicity on plasma metabolites**

4 Valine is one of amino acid in proteins. It belongs to the branched chain amino acids
5 which may play an important role in myocardial ischemia as energy substrates for
6 the heart.²⁴ It had been proved that valine was an potential biomarkers in myocardial
7 ischemia rat models.²⁵ The decreased level of valine was also observed in
8 myocardial tissue due to doxorubicin administration¹⁷, indicating the existing of the
9 relationship between valine and DOX-induced toxicity. Arachidonic acid, which
10 takes part in arachidonic acid metabolism, belongs to unsaturated fatty acids. It was
11 found that doxorubicin toxicity can result in altered P450-mediated arachidonic acid
12 metabolism.²⁶ Besides, Arachidonic acid had been previously shown to mediate
13 inflammation.²⁷ Inflammation reaction can lead to kidney parenchymal cell death
14 and acute kidney injury.²⁸ It also had been proved that inflammation can lead to
15 fibrosis of kidney, finally inducing nephrotoxicity.²⁹ DOX had been reported to
16 induce inflammatory response in the model of DOX cardiotoxicity.³⁰ Other
17 metabolic profile analysis on heart tissue induced by doxorubicin also selected
18 arachidonic acid as potential biomarker,¹⁷ supporting that arachidonic acid was
19 related to DOX-induced toxicity and DOX may induce toxicity through active
20 regulation of the inflammatory pathway. Sphingosine and sphinganine are both
21 sphingolipids, participating in sphingolipid metabolism. Phytosphingosine is a kind

1 of phospholipid that took part in sphingolipid metabolism. The changed level of
2 sphingosine, sphinganine and phytosphingosine indicated that DOX may induce
3 toxicity by regulating sphingolipid metabolism. Glycocholic acid, a bile acid, had
4 proved to be a biomarkers of liver injury.³¹ Lysophosphatidylcholine (LPC) is a
5 relevant component of human plasma originating from lecithin-cholesterol
6 acyltransferase, hepatic secretion^{32, 33} or action of phospholipase A2,³⁴ which had
7 been suggested to play a functional role in the pathogenesis of various diseases,
8 including vasodilation,³⁵ inflammation³⁶ and atherosclerosis.³⁷ The change in LPC
9 content may be related to DOX-induced toxicity. The changed level of these
10 biomarkers may reveal the mechanism of DOX-induced toxicity in some content.

11 **Conclusion**

12 In this study, plasma metabolomics technology was used to identify toxic
13 metabolites and metabolic pathways related to doxorubicin-induced toxicity,
14 providing information for the causal mechanism of system toxicity induced by DOX.
15 Male Wistar rats were treated with DOX with the dose of 15 mg/kg. Clinical
16 chemistry analysis and histopathological examination showed that DOX caused liver,
17 kidney, and heart injury in rats. The metabolomics result showed that fifteen
18 metabolites were changed due to drug administration. Besides, Network analysis
19 proposed probable pathways of DOX related to toxicity, and imported into
20 Cytoscape for visualisation of the metabolomics result. The result showed that the
21 pathways including arachidonic acid metabolism, valine, leucine and isoleucine

1
2
3
4 1 biosynthesis, sphingolipid metabolism, glycerophospholipid metabolism and primary
5
6
7 2 bile acid biosynthesis mainly involved in the toxicity of DOX. The result indicated
8
9
10 3 that the built metabolomics method can be applied to research on the mechanism of
11
12
13 4 drug-induced toxicity, benefiting for later accurate predictions of drug toxicity.
