4 23 **Abstract:** A novel small molecular weight methomyl molecule-imprinted monolith
5
6 24 (MIM) was prepared inside a polypropylene pipette tip by polymerization reaction.
7
8
9 25 Then the pipette tip-based MIM micro solid-phase extraction (PT-MIM- μ -SPE)
10
11 26 method was developed for selective extraction of methomyl in aqueous solution. The
12
13 27 extraction parameters, such as the sample flow rate, sample volume and elution
14
15 28 solvent were investigated. By combining with high performance liquid
16
17 29 chromatography-ultraviolet detector, the PT-MIM- μ -SPE method showed a good
18
19 30 linear range of 0.6-1000.0 $\mu\text{g L}^{-1}$ with a low limit of detection 0.2 $\mu\text{g L}^{-1}$. The method
20
21 31 was also applied for the pretreatment of methomyl in various environmental water
22
23 32 samples. The relative recoveries were in the range of 84.9 to 105.1% with relative
24
25 33 standard deviations less than 9.0 %. The results showed that methomyl could be
26
27 34 selectively enriched and monitored from environmental water samples.

40 Methomyl; Environmental water.

1. Introduction

Methomyl whose trade name is Lannate belongs to carbamate pesticides. It is a systemic, broad spectrum insecticide and was registered for the use on more than 100 crops worldwide for control of pests on vegetables, soybeans, cotton, some fruit crops, and ornamentals owing to its broad spectrum of biological activity. Methomyl sprayed on croplands can easily migrate to environmental water. Hence, extensive use of methomyl may cause residues in environmental water. As an acetyl cholinesterase inhibitor, methomyl can cause nerve damage to people and animals, and is harmful to the environment and human health. In order to protect human health, the maximal residue limits (MRLs) of pesticides has been established in food and drinking water by the European Union and China, etc [1,2]. European Union requires the MRLs 0.1 $\mu\text{g L}^{-1}$ for individual pesticide and of 0.5 $\mu\text{g L}^{-1}$ for total pesticides in drinking water [1], while in China, the MRLs of pesticides in drink water are in the range of 0.01-10 $\mu\text{g L}^{-1}$ (GB/T 5750.9-2006). Therefore, sensitive and selective methods are desirable in the determination of pesticides in environmental water.

For the sensitive detection of carbamate pesticides in water sample, high performance liquid chromatography (HPLC) and liquid chromatography-mass spectrometry (LC-MS) were often used due to the low thermal stability of carbamate pesticides, which were supposed to be sensitive, reliable and suitable [3-6].

Sample preparation is a crucial step during the whole analysis process especially in the analysis of trace level of pesticide residues from complicated matrix-based samples. Conventional extraction methods for the determination of pesticide residues

1
2
3
4 67 were based on liquid-liquid extraction (LLE) and solid phase extraction (SPE).
5
6 68 Compared with LLE, SPE has the advantages of simplicity, rapidly and less
7
8
9 69 consumption of organic solvents. However, the common nonselective sorbents used in
10
11 70 SPE usually result in coextraction of many matrix components. Although immune
12
13 71 affinity extraction (IAE) is capable of differentially adsorb target analytes, it still has
14
15 72 some disadvantages such as lack of stability and high cost of antibody preparation.
16
17
18 73 Molecular imprinting is a technique which can create the artificial receptor-like
19
20
21 74 binding sites with a “memory” for the shape and functional group positions of the
22
23 75 template molecule. So, molecularly imprinted polymers (MIPs) are good alternatives
24
25 76 to biological substances. MIPs can be synthesized conveniently by a mixture of
26
27
28 77 solution containing template molecule, porogenic reagent, functional monomer,
29
30
31 78 cross-linker and initiator. After polymerization, template molecules are removed and
32
33
34 79 polyporous materials with selectively functional binding sites are obtained. Due to the
35
36 80 high stability, ease of preparation, and high sensitivity, MIPs have been used widely in
37
38
39 81 different applications, such as chromatographic stationary phases [7,8], solid phase
40
41 82 extraction (SPE) [9-12], catalysis and sensing [13-18]. MIPs-based SPE is one of the
42
43
44 83 most successful and useful application. MIPs based SPE combines both the
45
46 84 advantages of MIPs and SPE, and exhibits good extraction efficiency, reusability and
47
48
49 85 selectivity to certain kinds of analytes [19], which is promising to selectively and
50
51 86 effectively extract drugs in complicated matrix. The most widely used technique for
52
53
54 87 preparing MIP materials is by conventional free-radical solution polymerization. In
55
56 88 order to acquire particles with the appropriate size for HPLC and SPE, the bulk MIPs
57
58
59
60

1
2
3
4 89 have to be crushed, grounded and sieved. The particles produced in this
5
6 90 time-consuming process are irregular in size and shape, resulting in significant loss in
7
8 91 chromatographic performance [20]. In addition, some active sites are destroyed during
9
10 92 the grinding process leading to lower MIP loading capacity. To overcome these
11
12 93 disadvantages, the molecularly imprinted monolithic (MIM) columns were prepared
13
14 94 by in situ polymerization directly inside a capillary or stainless steel or the tip of a
15
16 95 pipette. This method could avoid the tedious grinding and sieving procedures as well
17
18 96 as the problems of costly particle loss, particles in homogeneity, and molecular
19
20 97 imprinted spots loss and could easily obtained a MIM with the ideal porous structure
21
22 98 and low back pressure at a high flow rate [21]. To use the synthesized MIM directly as
23
24 99 SPE sorbents is a promising method. Recently, Zheng et al. [22] prepared a MIM
25
26 100 inside a fused-silica capillary and applied it in the extraction of fluoroquinolones from
27
28 101 milk samples. Some research groups, including ours, prepared MIM in a pipette tip
29
30 102 for the selective micro-solid phase extraction of residue level of drug and pesticide
31
32 103 from complicated matrix [23-26]. Compared with SPE, the amount of sorbents and
33
34 104 the volume of eluting solvents could be reduced greatly if the MIM prepared in a
35
36 105 fused-silica capillary or a pipette tip, so the extraction efficiency could be increased as
37
38 106 a result [27]. Besides, the amount of template molecule required during monolith
39
40 107 preparation is much less than that of other methods [28]. Since the MIM that
41
42 108 synthesized in a capillary was fragile, and required tedious pretreatment process, the
43
44 109 pipette tip-based MIM microextraction is a promising technique for the selective
45
46 110 extraction of target analyte residues in complicated matrices.

1
2
3
4 111 To the best of our knowledge, MIP sorbents using small molecular weight
5
6 112 methomyl as the template molecule have not been reported, and no attention has been
7
8
9 113 paid to make use of MIM as the sorbent for high selective extraction of methomyl
10
11 114 from complex matrices. In this work, methomyl-MIM was synthesized in a pipette tip
12
13 115 for the first time. The pipette tip could match to a syringe without any other treatment
14
15 116 to perform the molecularly imprinted monolith micro-solid phase extraction
16
17 117 (PT-MIM- μ -SPE). The MIM was applied for the selective extraction of methomyl.
18
19 118 Various experimental parameters affecting the pipette tip based methomyl-MIM- μ -
20
21 119 SPE were optimized. The optimized method based on PT-MIM- μ -SPE combined with
22
23 120 HPLC was established and applied for the determination of methomyl in various
24
25 121 environmental water samples.

7
8
9 135 Instruments Factory, China) was employed for pH measurements.
10

11 136

137 **2.2. Reagents and Chemicals**

138

139 Ethylene glycol dimethacrylate (EGDMA, 98% pure) was purchased from Acros
140 (New Jersey, USA). Methacrylic acid (MAA), Acrylamide (AM),
141 2,2'-bisisobutyronitrile (AIBN, AR), toluene (AR), dodecanol (AR), sodium
142 hydroxide (AR) and hydrochloric acid (AR) were obtained from Tianjin Kermel
143 chemical reagents development centre (Tianjin, China). methomyl, was purchased
144 from Sigma-Aldrich (St Louis, MO, USA), and its chemical structure is shown in
145 Fig. 1. Methanol (HPLC grade) and acetonitrile (HPLC grade) were ordered from
146 Tedia (Fair Lawn, New Jersey, USA). Sodium chloride was procured from Zhanyun
147 Chemical Co, Ltd. (Shanghai, China). Ultrapure water was purified on a Mill-Q water
148 purification system (Millipore Corporation, Billerica, MA, USA).

149 The stock standard solution of methomyl was prepared by weighing 2.5 mg
150 methomyl dissolved in 50 mL HPLC-grade methanol. Then the stock standard
151 solution at a concentration of 50 $\mu\text{g mL}^{-1}$ was made and stored at 4 $^{\circ}\text{C}$ in a refrigerator.
152 A series of standard solutions were daily prepared by an appropriate dilution from the
153 stock solution with ultrapure water.

154

155 **2.3. Sample preparation**

156

157 Reservoir water was collected from Danjiang Kou Reservoir (Danjiang Kou,
158 Hubei, China). South Lake water, farmland water and waste water were collected
159 from Wuhan (Wuhan, China). All of them were kept at 4 °C and filtered through a
160 0.45 µm polyether sulfone membrane which was purchased from Wuhan Shenshi
161 Chemical Industry Co. Ltd (Wuhan, China) prior to analysis.

162

163 **2.4. Preparation of Methomyl-Imprinted Monolith**

164

165 For the preparation of the methomyl-imprinted monolith, the template methomyl
166 (0.05mmol) was dissolved in porogenic solvents (50 µL toluene, 450 µL
167 1-dodecanol) in a glass vial and mixed with MAA (0.20 mmol) as the functional
168 monomer. The mixture was surged ultrasonically for 15 min. In order to make the
169 template and the monomer assemble each other better, the mixture was placed in the
170 dark for two hours. Then, 1.00 mmol of cross-linker EGDMA and 0.032 mmol (5.3
171 mg) of initiator AIBN were added and degassed by ultrasonication for about 30 min.
172 Next, 60 µL of the homogeneous solution was filled into a pipette tip which had been
173 sealed at one end. Subsequently, the other end of the pipette tip was sealed with
174 silicon rubber. After polymerization at 65 °C for 24 h, the silicon rubber was removed.
175 The resultant MIM was washed with methanol to remove the template molecules. A
176 reference, non-imprinted monolith (NIM), was prepared simultaneously like the same

1
2
3
4 177 procedure, including washing, but in the absence of the template molecule.
5
6
7 178

8
9 179 **2.5 PT-MIM- μ -SPE procedure**
10

11 180

12
13
14 181 The prepared methomyl-imprinted monolith was applied for extraction of
15
16 182 methomyl in aqueous solutions. As shown in Fig. 2, solutions were put in the syringe
17
18 183 and loaded by a SN-50C6 syringe pump (Shengnuo Medical Equipment Co., Ltd.,
19
20
21 184 Shenzhen, China). For precondition, the MIM was washing with 1.0 mL methanol and
22
23
24 185 0.5 mL water, respectively. For extraction, an aliquot of 3.0 mL sample solution was
25
26 186 loaded at a flow rate of 0.15 mL min⁻¹. Then, The MIM was washed with 0.5 mL
27
28
29 187 water at a flow rate of 0.15 mL min⁻¹ to remove the matrix interferences. Lastly, the
30
31 188 analytes were eluted with 60 μ L acetonitrile at a flow rate of 0.05 mL min⁻¹. The
32
33
34 189 eluent solution in glass-lined pipe was injected into the HPLC system with an
35
36 190 autosampler for analysis directly.
37
38
39 191

40
41 192 **3. Results and discussion**
42
43
44 193

45
46 194 In order to obtain the optimized extraction conditions, enrichment factor (EF) and
47
48
49 195 Relative recovery (RR) were used to evaluate the extraction efficiency of MIM.
50

51
52 196
$$EF = \frac{C_{\text{elu}}}{C_0}$$

53
54

55 197 The EF was defined as the ratio between the analyte concentration in eluent (C_{elu})
56
57
58 198 and the initial concentration of analyte (C_0) within the sample solution.
59
60

$$RR\% = \frac{C_{found} - C_{real}}{C_{add}} \times 100\%$$

C_{found} represents the concentration of the analyte after adding a known amount of standard to the real sample, C_{real} is the concentration of the analyte in real sample, and C_{add} refers to the concentration of a known amount of standard that was spiked in the real sample.

The imprinting factor (IF) was used to evaluate the recognition abilities of the MIM:

$$IF = \frac{EF_{MIM}}{EF_{NIM}}$$

where the EF_{MIP} is the EF of methomyl extracted by MIM and EF_{NIP} is the EF of methomyl extracted by NIM monolith under the same conditions.

3.1. Preparation and evaluation of methomyl-imprinted monolith

3.1.1. Optimization of preparation conditions

Different functional monomers will construct different binding sites with template.

To improve the recognition and selectivity property of MIM, two different functional monomers, including MAA and AM were investigated. The results showed that MAA has the higher specific recognition ability for methomyl compared with AM. To realize the better selectivity, MAA was chosen as the functional monomer. The ratio between monomer and cross-linker can affect the pore size and capacity of the

1
2
3
4 220 reticular structure of the polymer [16]. Increasing the amount of cross-linker can
5
6 221 maintain the stability of the recognition sites and lead to high selectivity for the target.
7
8
9 222 But, on the other hand, too more amount of cross-linker would result in large density
10
11 223 and bad permeability of the polymer, which would decrease the extraction efficiency,
12
13
14 224 therefore, the proper ratio is required. In this study, the molar ratios of the monomer to
15
16 225 cross-linker ranged from 1:1 to 1:6 were investigated, respectively. The results
17
18
19 226 showed when the ratio was lower than 1:3, the MIM showed bad recognition ability
20
21 227 and the mechanical stability of the polymer was poor. However, when the ratio was
22
23
24 228 higher than 1:5, the backpressure is too high to allow the mobile phase to flow
25
26 229 through the monolith. So, 1:5 was chosen as the optimized ratio of the monomer and
27
28
29 230 cross-linker, and it was selected for further optimization.

31
32
33
34

3.1.2. The characterization and specific evaluation of the MIM

35
36
37
38
39

234 The MIM morphological structure was investigated by scanning electron
40
41 235 microscope (SEM). As can be seen in Fig. 3, there were many macropores and
42
43
44 236 flow-through channels inlaid in the network skeleton of methomyl-imprinted monolith,
45
46
47 237 which provided flow paths through the column. Due to the size and density of the
48
49 238 macropore network, the monolith had a high internal porosity and, consequently, low
50
51 239 column hydraulic resistance. The pores allowed the mobile phase to flow through with
52
53
54 240 low flow resistance.

56 241 FT-IR was performed to testify the successful preparation of

1
2
3
4 242 methomyl-imprinted monolith. As shown in the supplementary material Fig. 1S, the
5
6 243 infrared spectrogram of methomyl imprinted monolith was different from that of
7
8
9 244 methomyl and MAA. The characteristic peak of MAA was around at 1690 and 1631
10
11 245 cm^{-1} , which were corresponding to the C=O and C=C stretching of MAA. Compared
12
13
14 246 with the infrared spectrogram of MAA, the stretching vibration wide peak of
15
16 247 3000-3300 cm^{-1} and the peak of 1631 cm^{-1} became weak in the infrared spectrogram
17
18
19 248 of the associated MIM and NIM complexes. The C=O stretch vibration peak of 1690
20
21 249 cm^{-1} shifted to that of 1720 cm^{-1} . These results showed that the polymers have been
22
23
24 250 successfully synthesized.

25
26 251 In order to evaluate the selectivity of the MIM, imidacloprid and carbendazim
27
28 252 were tested as non-analogues (the supplementary material for the structure detail, Fig.
29
30
31 253 2S). For sampling, methomyl, imidacloprid and carbendazim standard solutions were
32
33
34 254 mixed and diluted using deionized water at a final concentration of 200 $\mu\text{g L}^{-1}$, 1.0 mL
35
36 255 of the mixed solution was loaded on the MIM and NIM at a flow rate of 0.15 mL
37
38
39 256 min^{-1} . 60 μL acetonitrile was used to elute analytes. The eluent was analyzed by
40
41
42 257 HPLC directly. As shown in Fig. 3S, the results indicated that the MIM had a higher
43
44 258 affinity for methomyl than NIM, where IF was 2.26. And MIM had weaker extraction
45
46
47 259 ability for both imidacloprid and carbendazim than NIM monolith. All these results
48
49 260 demonstrated MIM had the specific selectivity for methomyl.

50
51 261

52 53 54 262 **3.1.3. Recognition mechanism of MIM to methomyl**

55
56
57 263

1
2
3
4 264 Based on the above results, hydrogen bonds were expected to be formed among
5
6 265 methomyl and monomers (MAA) as a key interaction force for binding site
7
8
9 266 construction. The hydroxyl groups of MAA acted as hydrogen bond donors. The
10
11 267 higher hydrogen-bonding ability of the hydroxyl group in MAA and methomyl
12
13
14 268 enhanced the strength of the hydrogen bonding between methomyl and monomers and
15
16 269 thus yielded imprinted polymers with better recognition properties. The illustration of
17
18 270 the MIM and its molecular recognition was shown in Fig. 4S. Hydrogen bonds were
19
20
21 271 formed between methomyl and MAA, which led to the formation of a self-assembled
22
23 272 complex of methomyl and MAA. According to the structure information of MAA and
24
25 273 methomyl, three MAA molecules would form three hydrogen bonds with one oxygen
26
27
28 274 atom and two nitrogen atoms of methomyl. The ratio of methomyl/MAA was 1:3,
29
30
31 275 which was in agreement with our result, in which a ratio of 1:4 was used. A bit more
32
33 276 functional monomers were always required to ensure complete interaction between
34
35 277 functional monomers and templates, because some functional monomers remained
36
37
38 278 dissociative with the templates.
39
40
41 279

42 43 44 280 **3.2. Optimization of PT-MIM- μ -SPE conditions**

45
46 281
47
48
49 282 In order to obtain the best extraction efficiency of the PT-MIM- μ -SPE method,
50
51 283 several parameters such as the flow rate, volume, pH value, and salt concentration of
52
53 284 sample, and the type and volume of eluent were optimized in this study. Sample
54
55
56 285 solutions were spiked with methomyl at 0.20 $\mu\text{g mL}^{-1}$ to perform the experiments.
57
58
59
60

1
2
3
4 2865
6 287 **3.2.1. Effect of sample flow rate**
78
9 288

10
11 289 Sample flow rate was an important parameter for MIM microextraction, which
12
13 290 was possible to affect extraction efficiency of methomyl and the time of analysis. The
14
15 291 sample flow rate was optimized in the range of 0.05-0.25 mL min⁻¹. The results
16
17 292 indicated that no significant difference of peak areas among different flow rates,
18
19 293 indicating that sample flow rate have little influence on extraction efficiency in this
20
21 294 work. Considering the analysis time and monolith pressure, 0.15 mL min⁻¹ was
22
23 295 selected for further studies.
24
25
26
27
28

29 296

30
31 297 **3.2.2. Effect of eluent type**
3233
34 298

35
36 299 The selection of an appropriate eluent is of high importance for the
37
38 300 PT-MIM- μ -SPE process. Considering the consistency to the mobile phase used in
39
40 301 liquid chromatography, the eluent is limited to solvents such as methanol, acetonitrile
41
42 302 and purified water. 1.0 mL of 0.2 $\mu\text{g mL}^{-1}$ methomyl standard solution was used in the
43
44 303 PT-MIM- μ -SPE system, and then mobile phase (methanol/water (40/60; v/v)),
45
46 304 acetonitrile and methanol as eluent were tested. The results indicated that acetonitrile
47
48 305 as the eluent exhibited the highest peak area. Thus, acetonitrile was selected as the
49
50 306 eluent in the following experiments.
51
52
53
54
55

56
57 307
58
59
60

1
2
3
4 308 **3.2.3. Effect of sample volume**
5

6 309
7

8
9 310 The effect of sample volume was monitored by loading methomyl standard
10
11 311 solution (containing $0.2 \mu\text{g mL}^{-1}$ of the analyte) from 1.0 to 5.0 mL at a constant flow
12
13 312 rate. The eluent volume (methanol) was $60 \mu\text{L}$. The results showed that EF of
14
15 313 methomyl increased with the increasing of sample volume from 1.0 to 5.0 mL. This
16
17 314 indicates that the maximal extraction capacity was not achieved even when 5.0 mL of
18
19 315 sample solution was loaded. However, RR began to decrease when the sample volume
20
21 316 increased. To achieve satisfactory extraction efficiency within a short time, 3.0 mL of
22
23 317 sample solution was selected in the PT-MIM- μ -SPE procedure.
24
25
26
27

28 318
29

30
31 319 **3.2.4. Effect of eluent volume**
32

33 320
34

35
36 321 In order to study the effect of eluent volume on the extraction efficiency,
37
38 322 different volumes of eluent (acetonitrile) were tested. The experimental results
39
40 323 showed that $60 \mu\text{L}$ eluent was sufficient to elute more than 90% analyte from the
41
42 324 monolith. Moreover, further increasing the volume of the eluent was not preferred
43
44 325 because EF decreased with the increasing of eluent volume. Thus, $60 \mu\text{L}$ of eluent
45
46 326 volume was selected for subsequent work.
47
48

49 327
50

51
52
53 328 **3.2.5. Effect of sample pH**
54

55 329
56
57
58
59
60

1
2
3
4 330 Sample pH was one of most important parameters for PT-MIM- μ -SPE which
5
6 331 may affect the molecule form of the analyte and closely relate to the interaction
7
8 332 between analytes and the MIM. The effect of the sample pH on the extraction
9
10 333 efficiency for methomyl was investigated using several buffer solutions with pH
11
12 334 2.0-9.0. The results showed that from pH 2.0 to 3.0, the peak area of methomyl
13
14 335 increased along with the increase of pH, and decreased when pH increased. The low
15
16 336 responses observed at low pH may be attributed to the protonation of methomyl
17
18 337 molecules. These protonated charged molecules were disadvantageous for the
19
20 338 formation of hydrogen bonds between MAA and methomyl which led to that the
21
22 339 methomyl molecules could not be adsorbed by the polymer. The decrease of the peak
23
24 340 area at higher sample pH could be explained by the deprotonation of carboxyl in
25
26 341 imprinted sites and the deprotonation charged imprinted sites could not adsorb analyte
27
28 342 effectively. Thus, pH 3.0 was chosen as the optimal pH of the sample.
29
30
31
32
33
34
35
36
37
38

39 344 **3.2.6. Effect of salt concentration**

40
41 345
42
43 346 The effect of salt concentration of the sample on the extraction efficiency was
44
45 347 also investigated. The results indicated that EF and RR increased as the concentration
46
47 348 of NaCl increased from 0% to 30% (w/v). Addition of salt into the sample solutions
48
49 349 could lead to the salting-out effect, and more analyte molecules would be extracted
50
51 350 onto the MIM. To obtain high extraction efficiency, 30% NaCl (w/v) was added in the
52
53 351 sample solution in the following experiments.
54
55
56
57
58
59
60

352

3.3. Evaluation of the method

354

355 By coupling with HPLC, the established method was applied for determination of
356 methomyl in environmental water samples. Analytical performance of the method was
357 validated, including linear range, coefficient (R), the limit of detection (LOD), the
358 limit of quantification (LOQ) and reproducibility. As listed in Table 1. Good linearity
359 ($R=0.9998$) was obtained in the range of $0.6-1000.0 \mu\text{g L}^{-1}$. LOD, which indicated the
360 sensitivity of the analytical method, was evaluated and found to be $0.2 \mu\text{g L}^{-1}$ ($S/N=3$).
361 LOQ was $0.6 \mu\text{g L}^{-1}$. The reproducibility of the method was determined by the
362 intra-day and inter-day precisions at the concentration of $0.2 \mu\text{g mL}^{-1}$ in spiked
363 environmental water samples for methomyl, respectively. The results showed that the
364 intra-day precisions (RSDs) was 3.4%, while the inter-day precisions (RSDs) was
365 4.1%, indicating good reproducibility of the method.

366

3.4. Real samples analysis

368

369 To evaluate its applicability and accuracy, the developed PT-MIM- μ -SPE -HPLC
370 method was applied for the determination of methomyl in environmental water
371 samples. The results were listed in Table 2, trace amounts of methomyl was detected
372 in reservoir water and farmland water. To investigate the extraction recoveries, four
373 kinds of water samples, all spiked at concentrations of $5 \mu\text{g L}^{-1}$, $50 \mu\text{g L}^{-1}$, and $500 \mu\text{g}$

1
2
3
4 374 L⁻¹ were extracted under the optimized conditions. The relative recoveries were in the
5
6 375 range of 84.9 % and 105.1 %, with RSD less than 9.0% (n=3). The chromatograms of
7
8
9 376 blank and spiked farmland water samples after treated by MIM- μ -SPE and
10
11 377 NIM- μ -SPE were shown in Fig. 4. All the results demonstrated that the proposed
12
13
14 378 method was effective and reliable for the pretreatment and determination of methomyl
15
16
17 379 in environmental water samples.
18
19
20 380

21 381 **3.5. Comparison of PT-MIM- μ -SPE-HPLC-UV with Other Methods**

22 382

23
24
25
26 383 The efficiency of the presented PT-MIM- μ -SPE-HPLC-UV method for
27
28 384 environmental water samples was compared with that of other reported methods. As
29
30
31 385 listed in Table 3, PT-MIM- μ -SPE-HPLC-UV method was obviously cheaper than
32
33
34 386 other reported methods, and the LOD by the proposed method are comparable to
35
36
37 387 those reported in other papers. All these results revealed that the PT-MIM- μ -SPE was
38
39 388 a sensitive, simple, and reproducible technique that could be used for preconcentration
40
41 389 of methomyl in environmental water samples.
42
43
44 390

45 46 391 **4. Conclusion**

47
48
49 392 In this work, a novel methomyl-MIM has been synthesized for selective extraction
50
51 393 of methomyl in aqueous samples. The monolith could be connected with syringes in
52
53
54 394 different sizes simply without any other treatment to perform μ -SPE process. The
55
56
57 395 MIM showed high selectivity and enrichment ability for methomyl. The
58
59
60

1
2
3
4 396 PT-MIM- μ -SPE followed by HPLC-DAD was developed as an analytical method for
5
6 397 the sensitive and selective determination of methomyl in environmental water samples.
7
8
9 398 The experimental results revealed that this method had high selectivity, low organic
10
11 399 solvent consumption, good extraction efficiency and linearity over the investigated
12
13 400 concentration range. The performance of this procedure in the analysis of methomyl
14
15
16 401 in environmental water sample was satisfactory.
