4 23 **Abstract:** The high performance liquid chromatography-trandem mass spectrometry
5
6 24 was applied to the determination of the quaternary ammonium compoueds, including
7
8
9 25 dodecyltrimethyl ammonium bromide, dodecyldimethylbenzylammonium chloride,
10
11 26 tetradecyldimethylbenzylammonium chloride, hexadecyldimethylbenzylammonium
12
13
14 27 chloride and didectyldimethylammonium chloride in pork, beerliver, apple, spinach,
15
16 28 rice and white suger. The analytes were extracted using methanol-water mixture as
17
18
19 29 extraction solvent, and further purified with Oasis WCX cartridge. The separation of
20
21 30 quaternary ammonium compounds was performed on a CAPCELL PAK CR 1:4
22
23
24 31 column using acetonitrile-50 mmol /L ammonium format aqueous solution containing
25
26 32 0. 1 % formic acid as mobile phase in a gradient elution mode. The mass
27
28
29 33 spectrometric detection was operated by using electrospray ion source in the multiple
30
31 34 reaction monitoring mode. The results showed that the linear range for 5 quaternary
32
33
34 35 ammonium compounds was 5.00~500. 00 µg/L, and the correlation coefficients were
35
36 36 higher than 0. 995. The limit of quantification for the analytes was 10.00 µg/L. Six
37
38
39 37 kind of real samples were analyzed and the recoveries of the analytes at three spiked
40
41 38 levels were between 76.8 % and 102.5 % with the relative standard deviations of
42
43
44 39 1.09 %~8.33 %. The present method is simple, reliable and accurate and can be
45
46 40 applied to the determination of quaternary ammonium compounds in foodstuffs.

1 Introduction

Quaternary ammonium compounds (QACs) contain a quaternary nitrogen. In the simplest case, alkyl chains of different lengths are attached to the nitrogen atom, although the quaternary nitrogen may also be part of a ring system (such as pyridine or piperidine) [1]. QACs belong to the group of cationic surfactants and are located at the phase boundary between the organic and water phase [2]. Quaternary ammonium surfactants are high-production-volume chemicals that constitute a large fraction of the cationic surfactant market[3,4]. The QACs are an economically important class of industrial chemicals. Because of their physical and chemical properties QACs are widely used as biocides, drugs and herbicides[5,6]. Disinfectants based on QACs are widely used in hospital environments and the food industry due to their low toxicity to humans and animals[7,8]. The focus on safe food and production of refrigerated food has led to the increasing use of QACs in the food industry[8,9]. The QACs were also used as fabric softeners, hair conditioners, emulsifying agents and constituents of room deodorizers, and sanitizers[10–12,2]. However, in recent years quaternary ammonium disinfectant poisoning death events have been reported[13]. The toxic effects of quaternary ammonium germicides have been described in detail[14]. Therefore, it is necessary to study residues of QACs in food.

Benzalkonium chloride (BAC) is a mixture of alkylbenzyltrimethylammonium chlorides in which the alkyl groups have a chain length from C8 to C18 [15–17]. This mixture is widely used as an active substance in anti-bacterial and antifungal products, such as preservatives and medical disinfectants[18,19]. The most common BACs are

1
2
3
4 67 C₁₂-BAC, C₁₄-BAC and C₁₆-BAC[20,21]. Other quaternary ammonium compounds,
5
6 68 such as dodecyltrimethylammonium bromide and didecyldimethylammonium
7
8
9 69 chloride are also commonly used as biocides and disinfectants.

10
11 BAC can be determined using liquid chromatograph (LC) with UV-detection in
12
13
14 71 aerosol preparations [22]and treated wood[23]. The capillary electrophoresis(CE) also
15
16 72 is an efficient separation method of ionic surfactants[24,1]. Recently, LC–MS was a
17
18
19 73 widely applied for analyzing samples because MS has higher sensitivity and
20
21
22 74 selectivity compared with LC detection[25–27,2]. Before determination of QAC,
23
24 75 sample preparation was required. The solid phase extraction (SPE) was widely
25
26 76 applied to perform the analyte concentration[28,29,5].

27
28
29 77 In this study, a HPLC–MS/MS was developed and applied for determination of
30
31
32 78 quaternary ammonium compounds in food samples. SPE was applied to the treatment
33
34 79 of the samples. The determination of the analytes in food samples have not been
35
36
37 80 reported. The present method has high sensitivity and is suitable for routine
38
39 81 determination of these analytes in real samples.

40 41 82 **2 Materials and methods**

42 43 83 **2.1 Reagents and chemicals**

44
45
46 84 Quaternary ammonium compounds, including dodecyltrimethylammonium
47
48
49 85 bromide (DTAB), dodecyldimethylbenzylammonium chloride (C₁₂-BAC),
50
51
52 86 tetradecyldimethylbenzylammonium chloride (C₁₄-BAC),
53
54 87 hexadecyldimethylbenzylammonium chloride (C₁₆-BAC) and
55
56
57 88 didecyldimethylammonium chloride (DDAC) were obtained from Sigma–Aldrich
58
59
60

1
2
3
4 89 (Shanghai, China) and the purities of the compounds are greater than 98 %. The
5
6 90 chemical structures of the compounds are presented in Fig.1. HPLC grade acetonitrile
7
8
9 91 (ACN), methanol (MeOH) and formic acid (99 %) were purchased from Fisher
10
11 92 Scientific (NJ , USA). Ammonium formate and ammonia solution (25 %) are of
12
13 93 analytical grade and supplied by Merck(Shanghai,China). C18 (200 g/3mL) Sep-Pak
14
15 94 cartridge was obtained from Supelco (Bellefonte, PA, USA). Oasis WCX (60 mg/3
16
17 95 mL), Oasis HLB (60 mg/3 mL) and Oasis MCX (60 mg/3 mL) SPE cartridges were
18
19 96 purchased from Waters Corp. (Milford, MA, USA). Ultrapure water was obtained
20
21 97 with a Milli-Q system (Millipore Co., MA, USA).

22
23
24
25
26 98 Stock solutions of individual compounds were prepared by dissolving each
27
28 99 compound in methanol at a concentration of 1000mg/L . Mixed standard solution was
29
30
31 100 prepared in methanol at 10 mg/L. Working solutions were obtained by dilution as
32
33
34 101 required. All solutions were kept in glass vials and stored at 4 °C.

35 36 102 **2.2 apparatus**

37
38
39 103 The Agilent 1100series HPLC system, equipped with a quaternary pump, auto
40
41 104 sampler, degasser and column department (Agilent TechnologiesInc., USA) was used.
42
43
44 105 Applied Biosystems API 4000 triple quadrupole mass spectrometer with electrospray
45
46 106 ionization (ESI) interface and Analyst 1.5 software (AB SCIEX,USA) was used.
47
48
49 107 Allegra™X-22R Benchtop Highspeed refrigerated centrifuge was purchased from
50
51 108 Beckman coulter,Inc. (Calif.,CA, USA). KQ-250B Ultrasonic generator was
52
53
54 109 purchased from Kunshan Instruments Inc. (Kunshan, Jiangsu, China). The
55
56 110 Vortex-Genie 2 was purchased from Scientific Industries (NY, USA).

111 2.3 Samples

112 Samples (pork, beer liver, apple, spinach, rice and white sugar) were purchased
113 from local supermarket (Changchun, China). The pork, beer liver, apple and spinach
114 were chopped and homogenized with food processor. The rice samples were
115 triturated and passed through the 2.0 mm sieve. The white sugar was used directly.
116 The spiked samples containing QACs were prepared by spiking the mixed working
117 solutions into the samples and vortexing for 5 min. The resulting pork, beer liver,
118 apple and spinach samples were stored at -18 °C and other samples were stored at
119 4 °C until analysis. Except for the experiments mentioned in Section 3.3.3, which
120 were performed with all samples, all other results were obtained with rice sample.

121 2.4 Extraction and cleanup

122 2.00 g of sample was placed into a 50 mL polytetrafluoroethylene centrifuge tube.
123 10.00 mL of methanol/water (90:10, v/v) was added into the tube. The sample was
124 vortexed for 30 s, then sonicated for 15 min, and finally centrifuged at 10000rpm for
125 5min at -4 °C. The supernatant was transferred to another 50 mL centrifuge tube. The
126 residues were re-extracted with 10.00 mL of methanol/water (80:20, v/v). All
127 supernatants were combined in the tube for further purification with Oasis WCX SPE
128 cartridge.

129 The WCX cartridge was pre-conditioned with 3 mL of methanol, followed by 6
130 mL of water. Then, the resulting supernatant was loaded at a flow rate of 3 mL·min⁻¹.
131 The cartridge was washed with 3 mL of 5 % (v/v) ammonia solution and 3 mL of
132 methanol. Next, the analytes were eluted with 6.00 mL of the mixture of formic

1
2
3
4 133 acid/methanol (2:98, v/v). The eluate was evaporated under a steam of nitrogen gas at
5
6 134 40°C. Finally, the residue was dissolved in 1.00 mL of ammonium formate aqueous
7
8
9 135 solution (0.1 % formic acid)/ acetonitrile and filtered with a 0.22 µm nylon filter
10
11 136 (Millipore, Carrigtwohill, Ireland) before analysis.

137 **2.5 LC–MS/MS analysis**

138 The chromatographic separation was performed on a CAPCELL PAK CR 1:4 (150
139 mm×2.0 mm, 5.0 µm) column in gradient elution mode. The mobile phase consisted
140 of 0.1 % formic acid – 50 mmol·L⁻¹ ammonium formate aqueous solution (A) and
141 acetonitrile (B). The gradient program is as follows: 0~3.0 min: 45 % A; 3.0~10.0
142 min:45~10 % A; 10.0~13.0 min: 10 % A; 13.0~13.1 min: 10~45 % A; 13.1~20.0
143 min: 45 % A. The flow rate of mobile phase was set at 0.30 mL·min⁻¹ and column
144 temperature was kept at room temperature. Injection volume was 10.0 µL.

145 Mass spectrometric analysis was carried out using an ESI source in positive
146 ionization mode. The operation conditions are as follows: ion spray voltage (IS), 5500
147 V; source temperature at 550.0 °C; curtain gas (CUR), 35.0 psi; ion source gas 1, gas
148 2 at 65.0 psi and 55.0 psi, respectively; collision-induced dissociation (CAD) gas, 8.0
149 psi. The Multiple reaction monitoring (MRM) mode was applied for quantitative
150 analysis. The optimized parameter values for detecting quaternary ammonium
151 compounds are shown in Table 1.

152 **3 Results and discussion**

153 **3.1 Sample preparation**

154 The some reagents, including water, methanol, ethanol, acetonitrile and acetone

1
2
3
4 155 were used as extraction solvents. The effect of type of extraction solvents on the
5
6 156 recoveries of the analytes are shown in Fig.2. When water, ethanol and acetone are
7
8
9 157 used as extraction solvents, recoveries of the target compounds are low. When
10
11 158 methanol and acetonitrile were used, the recoveries of the analytes are high and close.
12
13 159 Considering the toxicity of acetonitrile is higher than that of methanol, the methanol
14
15
16 160 was used as the extraction solvent. The effect of methanol concentration was
17
18
19 161 investigated and the experimental results are shown in Fig.3. When the methanol
20
21 162 concentrations are lower 70 %, recoveries of all the analytes are low. High recoveries
22
23 163 can be obtained for C₁₂-BAC, C₁₄-BAC, C₁₆-BAC and DTAB when 90% methanol is
24
25
26 164 used as extraction solvent. However, the recovery of DDAC is low. The recoveries for
27
28
29 165 C₁₄-BAC, C₁₆-BAC, DTAB and DDAC are high and the recovery of C₁₂-BAC is low
30
31 166 when 80% methanol is used. In order to obtain high recoveries of all the analytes, the
32
33 167 extraction was carried first using 90% methanol, and then using 80% methanol as
34
35
36 168 extraction solvents.

37
38
39 169 The SPE cartridges including C18, Oasis HLB, Oasis WCX and Oasis MCX were
40
41 170 used. When the standard solution was passed through the four types of cartridges the
42
43
44 171 recoveries of analytes were examined and the experimental results are shown in Fig.4.
45
46 172 The recoveries of QACs are very low when the C18 and Oasis MCX cartridges are
47
48
49 173 used. The recoveries of QACs range form 78.7 % to 85.2 % when Oasis HLB was
50
51 174 used. High recoveries (90.8 %~101.4 %) for all analytes were obtained when the
52
53
54 175 WCX cartridge was used. Therefore, the WCX cartridge was selected for the
55
56
57 176 following experiments.
58
59
60

1
2
3
4 177 The volume of elution solvent is also a crucial parameter that could have an effect
5
6 178 on the recoveries of analytes. Under the same experimental conditions, 10.00 mL of
7
8
9 179 formic acid-methanol (2:98, v/v) was used as the elution solvent. 1.00 mL of eluate
10
11 180 was collected in a tube each time. The each eluate was analyzed and the analytical
12
13 181 results are shown in Fig.5, the experimental results indicate that the all analytes can be
14
15
16 182 completely eluted with 6.00 mL of elution solvent. However, because all elution
17
18
19 183 solvent will be evaporated, so 10.00 mL of elution solvent should be used.

184 **3.2 Optimization of HPLC–MS/MS determination**

185 The MS/MS parameters were optimized by injecting a standard solution of 1 mg/L
186 of each analyte directly into the MS system at a flow rate of 0.01 mL/min. The ESI
187 positive and negative modes were evaluated. The results suggested that all QACs
188 were ionized in positive ion mode, so positive ion mode was chosen. MS parameters
189 for the target analytes were optimized in positive electrospray ionization full scan
190 mode. The MS/MS conditions were adjusted in collision-induced dissociation (CID)
191 mode under various collision energies. Each compound was detectable in the form of
192 $[M-Cl]^+$ ion except for DTAB, which forms a stable $[M-Br]^+$ ion. For these compounds,
193 $[M-Cl]^+$ ions and $[M-Br]^+$ ion were selected as the precursor ions. Two MRM
194 transitions were monitored and the most sensitive transition was chosen for
195 quantitative analysis. The optimal parameters for each compound are shown in Table
196 1.

197 The HPLC conditions was studied with three analytical columns including Ultra
198 C18 (150 mm×2.1 mm, 5 μ m, RESCEK), Atlantis HILIC silica (100 mm×2.1 mm, 3

1
2
3
4 199 μm , Waters) and CAPCELL PAK CR 1:4 (150 mm \times 2.00 mm, 5 μm , SHISEIDO).
5
6 200 Under the same LC gradient program and mobile phase composition, the resolution of
7
8 201 the analytes obtained with the CAPCELL PAK CR 1:4 column is higher than that
9
10 202 obtained with Ultra C18 and the Atlantis HILIC silica. The effect of the mobile phase
11
12 203 on chromatographic separation was studied. The effect of the concentration of formic
13
14 204 acid and ammonium formate in mobile phase A was examined and the results
15
16 205 indicated that when the concentrations of formic acid and ammonium formate were
17
18 206 0.1% and 50 mmol $\cdot\text{L}^{-1}$, respectively, the resolution was highest. So, 0.1 % formic
19
20 207 acid-50 mmol $\cdot\text{L}^{-1}$ ammonium formate aqueous solution/ acetonitrile was selected as
21
22 208 the mobile phase. Other parameters, such as column temperature, flow rate of mobile
23
24 209 phase and injection volume of the sample were studied in order to obtain high
25
26 210 resolution. The results showed that when the column temperature was room
27
28 211 temperature [18], the flow rate of the mobile phase was 0.3 mL/min and the volume of
29
30 212 sample was 10.0 μL the resolution was highest.

213 3.3 Method validation

214 The linear range, limit of detection (LOD), limit of quantification (LOQ), the
215 precision, and recovery of the present method were evaluated.

216 3.3.1 Linearity, LOD and LOQ

217 Under the optimal experimental conditions, the calibration curves were obtained
218 for all the target compounds. From Table 2 it is seen that the linear range is from the
219 5.00 $\mu\text{g/L}$ to 500.00 $\mu\text{g/L}$ and the correlation coefficients are greater than 0.995. The
220 LOD and LOQ for each analyte were determined as the lowest concentrations that

1
2
3
4 221 yield a signal-noise (S/N) ratio of 3.00 and 10.00, respectively. The LODs and LOQs
5
6 222 are listed in Table 2.
7

8 223 **3.3.2 Recovery and precision**

9
10
11 224 The recoveries of the analytes were evaluated by analyzing the spiked samples at
12
13 225 three spiked concentrations (10.00, 50.00 and 100.00 $\mu\text{g}\cdot\text{kg}^{-1}$). The results are
14
15 226 summarized in Table 3. The average recoveries of DTAB, C₁₂-BAC, C₁₄-BAC,
16
17 227 C₁₆-BAC and DDAC in spiked samples are from 76.8 % to 102.5 %. It can be noted
18
19 228 that relative standard deviation values are lower than 8.33 % at three concentration
20
21 229 levels. It was shown that the accuracy and the precision of the method developed are
22
23 230 acceptable.
24
25
26
27

28 231 **3.3.3 Analysis of real samples**

29
30
31 232 In order to check the applicability of the present method, the method was applied
32
33 233 to the determination of QACs in the six spiked samples including pork, beef liver,
34
35 234 spinach, apple, rice and white sugar. The recoveries and precision of analytes in the
36
37 235 six spiked samples are listed in Table 3. The total ion chromatogram of the extract of
38
39 236 rice sample is shown in Fig.6. The typical MRM chromatograms of blank and spiked
40
41 237 rice samples are shown in Fig.7.
42
43
44
45

46 238 **3.3.4 Comparison of the present method with other methods**

47
48
49 239 The performances of the present method were compared with those of
50
51 240 other methods reported for determining QACs in foodstuffs. These
52
53 241 methods include liquid-liquid extraction (LLE)[30]and QuEChERS [31].
54
55 242 The results are listed in Table 4. Compared with the reported methods,
56
57
58
59
60

1
2
3
4 243 when the present method was applied, the sample amount was smaller,
5
6 244 the toxicity of the extraction solvent was lower, the operation was simpler.
7
8
9 245 Considering the advantages, this study should be a satisfactory method.

10 11 246 **4. Conclusions**

12
13
14 247 In this study, a rapid and sensitive method was established for determination of
15
16 248 QAC residues in foodstuffs. High clean up efficiency was obtained using WCX-SPE
17
18
19 249 cartridge in the sample preparation. Under the selected experimental conditions, five
20
21 250 kinds of quaternary ammonium compounds can be completely separated in 20 min.
22
23
24 251 This method was validated with spiked samples and satisfactory recoveries were
25
26 252 obtained. The present method is relatively simple and accurate, and can be applied for
27
28
29 253 routine determination of these analytes in real samples.

Figure caption

Fig. 1 Structures of quaternary ammonium compounds .

Fig. 2 Effect of the type of extraction solvent from rice samples at concentration of $50.00 \mu\text{g}\cdot\text{kg}^{-1}$.

Fig.3 Effect of the different methanol aqueous solution from rice samples at concentration of $50.00 \mu\text{g}\cdot\text{kg}^{-1}$.

Fig.4 Recoveries of analytes obtained with different SPE cartridges from rice samples at concentration of $50.00 \mu\text{g}\cdot\text{kg}^{-1}$.

Fig.5 Recoveries of analytes obtained with different volume of elution solvent from rice samples at concentration of $50.00 \mu\text{g}\cdot\text{kg}^{-1}$

Fig.6 Total ion chromatogram of the extract of rice sample at the level of $50.00 \mu\text{g}\cdot\text{kg}^{-1}$.

Fig.7 Typical MRM chromatograms of blank rice (A) and spiked rice sample at the level of $50.00 \mu\text{g}\cdot\text{kg}^{-1}$ (B).

Fig.1 Structures of quaternary ammonium compounds .
223x143mm (96 x 96 DPI)

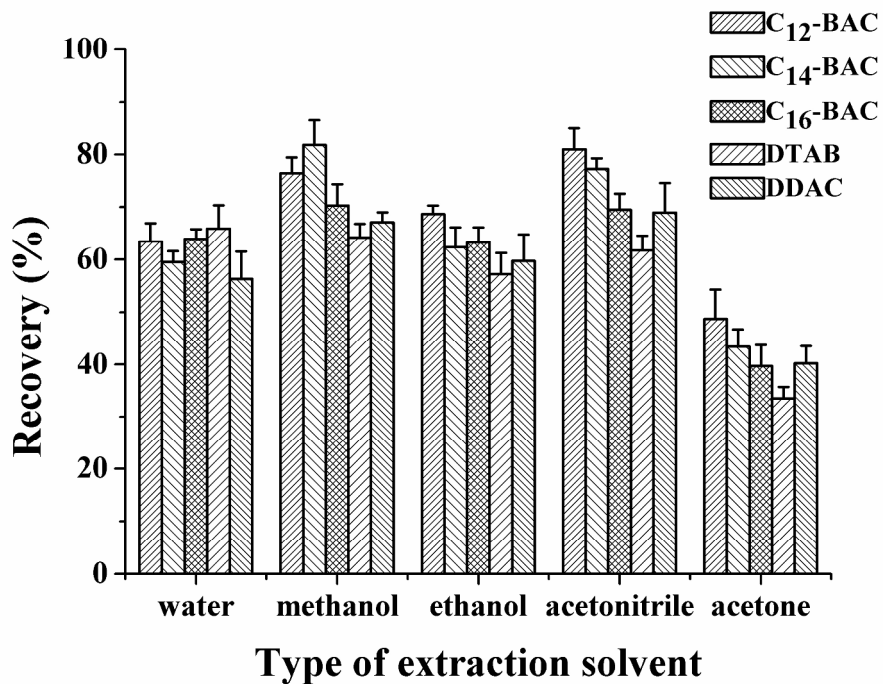

Fig. 2 Effect of the type of extraction solvent from rice samples at concentration of 50.00 $\mu\text{g}\cdot\text{kg}^{-1}$.

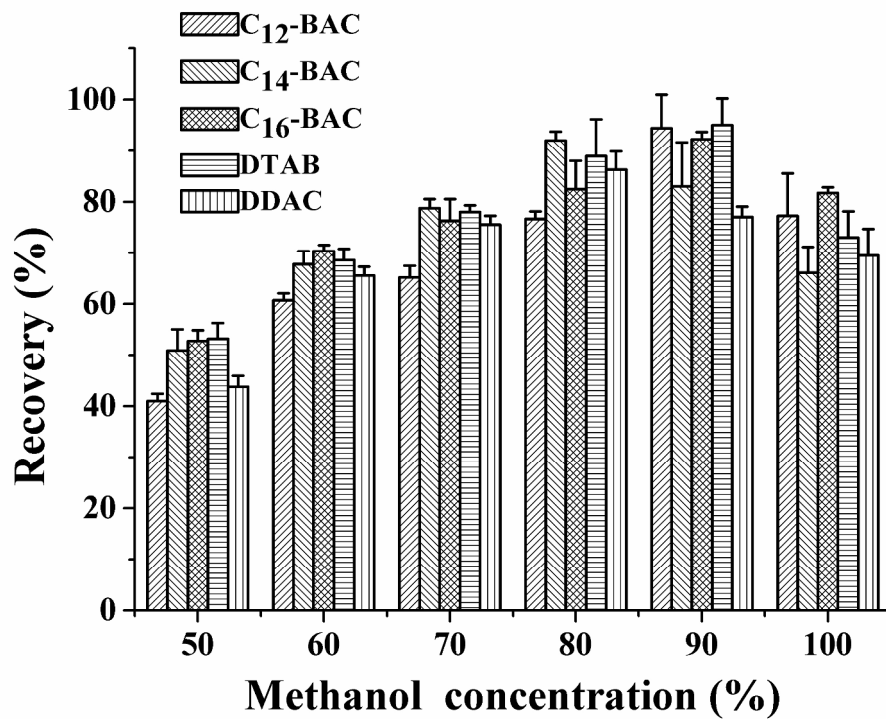

Fig.3 Effect of the different methanol aqueous solution from rice samples at concentration of $50.00 \mu\text{g}\cdot\text{kg}^{-1}$.
268x225mm (300 x 300 DPI)

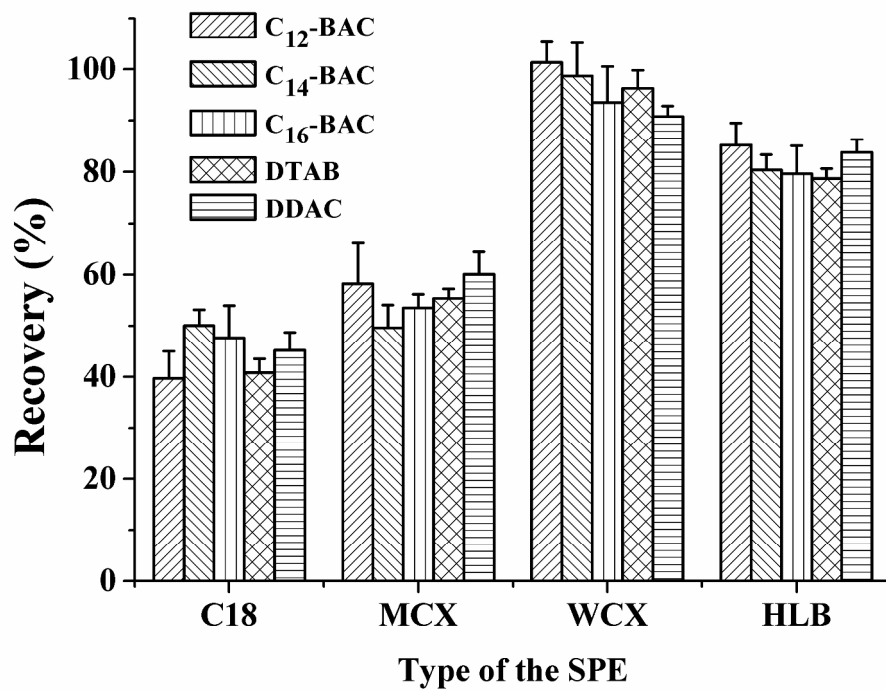

Fig.4 Recoveries of analytes obtained with different SPE cartridges from rice samples at concentration of 50.00 $\mu\text{g}\cdot\text{kg}^{-1}$.
268x216mm (300 x 300 DPI)

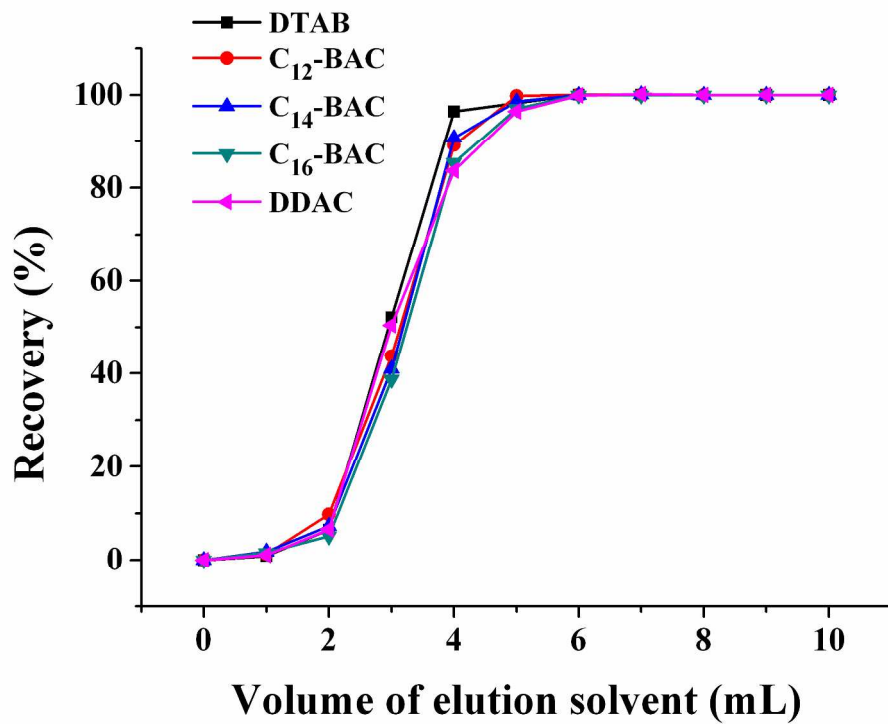

Fig.5 Recoveries of analytes obtained with different volume of elution solvent from rice samples at concentration of $50.00 \mu\text{g}\cdot\text{kg}^{-1}$
270x230mm (300 x 300 DPI)

Fig.6 Total ion chromatogram of the extract of rice sample at the level of $50.00 \mu\text{g}\cdot\text{kg}^{-1}$.
266x71mm (96 x 96 DPI)

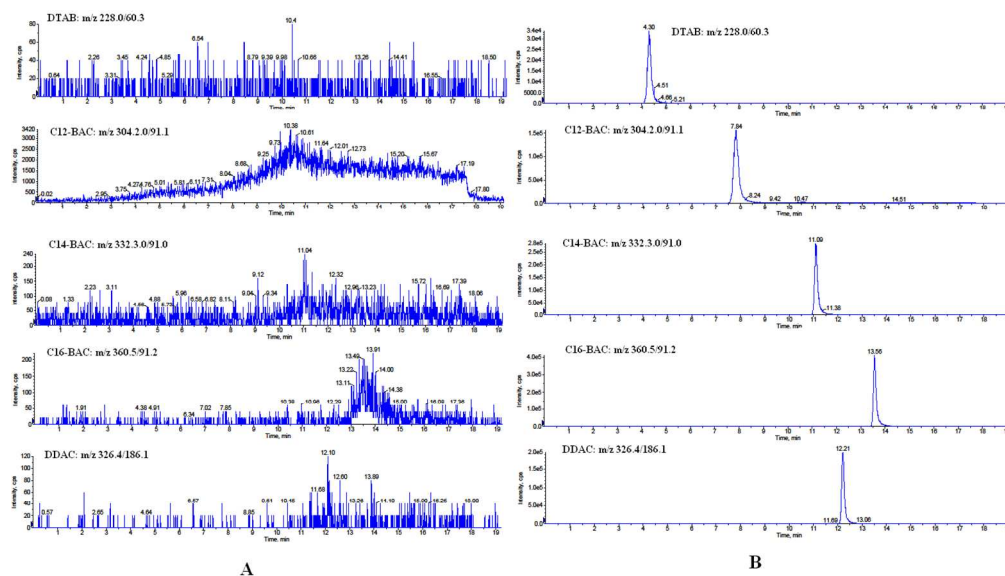

Fig.7 Typical MRM chromatograms of blank rice (A) and spiked rice sample at the level of 50.00 $\mu\text{g}\cdot\text{kg}^{-1}$ (B).

399x234mm (96 x 96 DPI)

Table 1 MS/MS parameters of the quaternary ammonium compounds.

Compounds	Precursor ion m/z	Production ions m/z	CE (eV)	DP (V)	Retention time(min)
DTAB	228.0	57.0	33	90	4.89
		60.3*	42	90	
C ₁₂ -BAC	304.0	91.1*	46	50	7.34
		212.3	29	50	
C ₁₄ -BAC	332.3	90.0*	50	95	11.25
		240.0	31	95	
C ₁₆ -BAC	360.5	91.2*	60	100	14.83
		268.3	32	100	
DDAC	326.0	57.0	40	60	18.46
		186.1*	53	60	

* Quantitative ion.

Table 2 Linear equation, correlation coefficient, linear range, LOD and LOQ

Analyte	Regression equation	Correlation coefficient	Linear range ($\mu\text{g/L}$)	LOD ($\mu\text{g/kg}$)	LOQ ($\mu\text{g/kg}$)
C ₁₂ -BAC	$A = 1.44e^5c + 2.05e^6$	0.9988	5.00-500.00	3.00	10.00
C ₁₄ -BAC	$A = 1.38e^5c + 2.54e^6$	0.9976	5.00-500.00	3.00	10.00
C ₁₆ -BAC	$A = 1.62e^5c + 4.81e^6$	0.9955	5.00-500.00	3.00	10.00
DTAB	$A = 3.05e^4c + 1.75e^5$	0.9997	5.00-500.00	3.00	10.00
DDAC	$A = 1.06e^5c + 1.48e^6$	0.9996	5.00-500.00	3.00	10.00

Table 3 Recoveries and precision for determining the analytes in spiked samples

Analyte	added ($\mu\text{g}/\text{kg}$)	C ₁₂ -BAC		C ₁₄ -BAC		C ₁₆ -BAC		DTAB		DDAC	
		Recovery/%	RSD/%	Recovery/%	RSD/%	Recovery/%	RSD/%	Recovery/%	RSD/%	Recovery/%	RSD/%
