5

6 25 Due to catechins (CCs) play an important role in human health, we proposed a new CCs
7
8 26 detection method relying on a novel fluorescence “off-on” switch system. Water-soluble cationic
9
10 27 polythiophene derivatives, denoted as poly
11
12 28 3-{{[1-(2-hydrazino-2-oxopropyl)piperidin-4-ylidene]methyl}thiophene hydrochloride
13
14 29 (PMTH • HCl), was prepared as a novel fluorescent material. Initially, the fluorescence of
15
16 30 PMTH • HCl can be quenched by Cu²⁺, as the spontaneous formation of Cu²⁺ - PMTH • HCl
17
18 31 assembling dyads, resulting in fluorescence turn off. Then, on addition of CCs in Cu²⁺ -
19
20 32 PMTH • HCl, Cu²⁺ was separated from PMTH • HCl, producing free PMTH • HCl and stable
21
22 33 complex Cu²⁺-CCs, so as to turn on the fluorescence signal of PMTH • HCl. Meanwhile, the
23
24 34 mechanisms of fluorescence quenching and recovery were discussed to provide new thoughts to
25
26 35 design sensor based on water-soluble conjugated polymers. This fluorescence “off-on” signal was
27
28 36 sensitive to the concentration of CCs. Under optimized condition, the fluorescence intensity was
29
30 37 linear to CCs concentration varying from 1.0×10⁻⁸ to 9.0×10⁻⁶ mol/L (γ = 0.9968), with a detection
31
32 38 limit of 3.34×10⁻⁹ mol/L. Therefore, an efficient, sensitive, highly selective and practically
33
34 39 applicable detection system for CCs has been designed.

1. Introduction

Tea, including green and red tea, is becoming a more popular drink in the world, due to a number of bioactive chemicals, particularly rich in catechins (CCs). CCs, belonging to the family of flavonoids, have been shown to play an important role in human health with attention to their various biological and pharmacological effects¹⁻⁴, such as anti-carcinogenic activities, anti-oxidant activities, anti-inflammatory and reducing obesity. Therefore, a simple and reliable analytical method for the detection of CCs is a pressing need in developing high quality tea product. To date, many methods such as electrochemical detection^{4,5}, high-performance liquid chromatography⁶⁻⁹ and chemiluminescence¹⁰ have been established for assaying CCs. However, these protocols are insensitive, time-consuming and laborious. In recent years, researchers made significant progress in developing “off-on” switch system¹¹⁻¹⁵. The “off-on” switch system could provide accurate results because of the specific adsorption and it is not restricted in the detection compared with “turn-off”^{16,17} or “turn-on” switch system¹⁸⁻²⁰.

Fluorescent probes play an important role in designing fluorescence sensors. Water-soluble conjugated polymers (CPs)²¹⁻²⁵ as optical transducers provided a useful platform for constructing high sensitive chemo-sensors and bio-sensors, owing to good water solubility, light-harvesting, electrical, and strong fluorescence properties. Meanwhile, CPs have the characteristics of amplification and superquenching properties²⁶⁻²⁸, thanks to delocalized electronic structures, the rapid transfer of excitation throughout an isolated conjugated polymer chains²⁹ is supported. As a result, CPs offered many sensing advantages³⁰⁻³⁴ for fluorescence sensors compared with quantum dots^{35,36} and small molecule dyes³⁷.

Based on the above facts, we used a novel water-soluble conjugated polymer denoted as poly

68 3-[[1-(2-hydrazino-2-oxopropyl)piperidin-4-ylidene]methyl]thiophene hydrochloride

69 (PMTH • HCl) to develop a novel “off-on” switch system for the detection of CCs. In the system,

70 the fluorescence of PMTH • HCl was efficiently quenched by the quencher Cu^{2+} , so as to turn off

71 the fluorescence signal. Based on the stronger affinity between CCs and Cu^{2+} , addition of CCs can

72 remove Cu^{2+} away from PMTH • HCl, resulting in fluorescent turn-on.

73 2. Experimental

74 2.1. Reagents and apparatus

75 All chemicals were of guaranteed analytical grade. Double distilled water was used in all

76 experiments. CCs were purchased from Sigma-Aldrich.

77 Infrared spectra (IR) were recorded in potassium bromide pellets on a Perkin Elmer 1750. ^1H

78 NMR and ^{13}C NMR was measured on a Bruker AV III400. Fluorescence measurements were

79 carried out on a RF-5301 fluorescence spectrophotometer.

80 2.2. Synthesis of PMTH • HCl

81 PMTH • HCl was synthesized according to literature ³⁸. Firstly,

82 4-(thiophen-3-ylmethylidene)piperidine was used as starting material and then through

83 nucleophilic addition reaction, hydrazinolysis reaction, and oxidative polymerization. PMTH

84 was obtained after purification treatment by chromatography. PMTH • HCl was synthesized by

85 acidification in chloroform. The structure is described as follows (Scheme 1).

86 (Scheme 1)

87 2.3. Fluorescence measurement

88 1.0 mL (1.0×10^{-5} mol/L) of Cu^{2+} was added to a solution of 1.0 mL (2.5×10^{-5} mol/L) of

89 PMTH • HCl and 10 mL of Tris-HCl solution (pH 7.8) in 10 mL colorimeter tube. Upon addition of

90 CCs in PMTH • HCl, fluorescence recovered. The fluorescence spectra were recorded with
91 emission at 515 nm, excitation at 410 nm and slit width at 10 nm.

92 2.4 Preparation of samples

93 For sample analysis, 1.0 g green tea or 5.0 g sun cream was immersed in anhydrous ethanol
94 (4:1 v/v) containing 0.10 mol/L HCl for 3 h. The mixture was filtrated and evaporated under
95 vacuum. The residue was dissolved in double distilled water. Human serum was mixed with
96 anhydrous ethanol (1:4 v/v), and then the mixture was allowed to stand at room temperature for 12
97 h. The supernatant was diluted 5 times after centrifugation.

98 3. Results and discussions

99 3.1. Fluorescence intensity changes of PMTH • HCl caused by Cu²⁺

100 Fluorescence spectroscopy could be used to explain the interaction between PMTH • HCl and
101 Cu²⁺ such as quenching mechanism. The fluorescence reduction efficiency increased quickly in
102 the first few minutes of reaction and the quenching system could maintain at least 6 h. On addition
103 of Cu²⁺, the fluorescence intensity of PMTH • HCl decreased, which indicated the strong
104 interaction of PMTH • HCl and Cu²⁺. When the Cu²⁺ concentration was less than 1.6×10⁻⁷ mol/L,
105 the fluorescence intensity was linear with the Cu²⁺ concentration (Fig. 1 (a)). Meanwhile, It could
106 be deduced that the molar ratio between PMTH • HCl and Cu²⁺ was 1:1, approximately.

107 The quenching mechanisms are usually divided into static quenching and dynamic quenching,
108 where static quenching results from the formation of non-luminous complex or intermolecular
109 complex between fluorophor and quenching agent and dynamic quenching is due to the collision.
110 In general, the values of quenching rate constant (K_q) were greater than the limiting diffusion rate
111 constant of the biopolymer (2 × 10¹⁰ L/mol·s), which indicated that the quenching mechanism of

1
2
3
4 112 followed a dynamic quenching. In order to testify that it is dynamic quenching, Stern-Volmer
5
6 113 equation was used:

7
8
9 114
$$I_0/I = 1 + K_{SV}[Cu^{2+}] = 1 + K_q\tau_0[Cu^{2+}] \quad (1)$$

10
11 115 Where I_0 and I are the fluorescence intensities in the absence and presence of quencher,
12
13 116 respectively. K_{SV} and K_q are the Stern-Volmer dynamic quenching constant and the quenching rate
14
15 117 constant. τ_0 , the lifetime of PMTH • HCl, is 10^{-8} s, approximately. According to the linear
16
17 118 regression plots of I_0/I vs. $[Cu^{2+}]$ (Fig. 1 (b)), the value of K_q is 8.98×10^{14} L/mol·s. Thus, the
18
19 119 suitable quenching follows a static quenching.

20
21
22
23
24 120 (Fig. 1)

25
26 121 In order to evaluate the binding affinity or the binding constant (K), the following equation
27
28 122 was used:

29
30
31 123
$$\lg [(I_0-I)/I] = \lg K + n \lg [Cu^{2+}] \quad (2)$$

32
33 124 The linear regression plots of $\lg [(I_0-I)/I]$ vs. $\lg [Cu^{2+}]$ which were analyzed at three different
34
35 125 temperatures (293K, 298K and 303K) yields $\lg K$ as the intercept and n (the number of bonding
36
37 126 sites) as the slope (Fig. 2). The calculated results were shown in Table 1. The large binding
38
39 127 constant indicated that the binding affinity is strong and Cu^{2+} was strong ion chelator to form
40
41 128 stable complex with PMTH • HCl. Meanwhile, the value of n and the molar ratio between
42
43 129 PMTH • HCl and Cu^{2+} testified the original description that the quenching mode was static.

44
45
46
47
48 130 (Fig. 2)

49
50
51 131 (Table 1)

52
53
54 132 There are four binding forces between macromolecule and small molecule³⁹: H-bonding,
55
56 133 Vander Waals, hydrophobic strength, and electrostatic. Vant't Hoff equation was used to study the
57
58
59
60

1
2
3
4 134 binding force between PMTH • HCl and Cu²⁺;

5
6 135
$$\ln (K_2 / K_1) = (\Delta H / R) \cdot (1 / T_1 - 1 / T_2) \quad (3)$$

7
8
9 136
$$\Delta S = -(\Delta G - \Delta H) / T \quad (4)$$

10
11
12 137
$$\Delta G = -RT \ln K = \Delta H - T\Delta S \quad (5)$$

13
14 138 Where ΔH , ΔS and ΔG are enthalpy change, entropy change and free enthalpy change,
15
16 139 respectively. According to the views of Ross⁴⁰, The negative ΔH and ΔS values are associated
17
18 140 with H-bonding and Van der Waals. The positive ΔH and ΔS values are characterized by
19
20 141 hydrophobic strength. Very low positive or negative ΔH and positive ΔS values are associated
21
22 142 with electrostatic interactions. The calculated results are revealed in Table 2. The negative ΔG
23
24 143 value indicated that it is a spontaneous process. The negative entropy (ΔS) and enthalpy (ΔH)
25
26 144 values indicated that the interaction forces were H-bonding and Van der Waals.

27
28
29
30
31 145 (Table 2)

32
33
34 146 *3.2 Performance evaluation of the fluorescence “off-on” switch system*

35
36 147 In this type of system, PMTH • HCl was allowed to interact with the quencher (Cu²⁺), which
37
38 148 can be attributed to strong Cu-N binding. Upon addition of CCs to Cu²⁺ - PMTH • HCl, oxygen
39
40 149 atom could bond with Cu²⁺ (Scheme 2). Therefore, CCs could remove Cu²⁺ away from
41
42 150 PMTH • HCl, which lead to the recovery of PMTH • HCl fluorescence (Fig. 3). The mechanism was
43
44 151 described in Scheme 3.

45
46
47
48 152 (Scheme 2)

49
50
51 153 (Fig. 3)

52
53
54 154 (Scheme 3)

55
56 155 The stability constants for complexes of CCs-Cu²⁺ and Cu²⁺- PMTH • HCl have been
57
58
59
60

1
2
3
4 156 determined by a potentiometric titration technique⁴¹⁻⁴⁴. The stability constants of CCs-Cu²⁺ and
5
6 157 Cu²⁺-PMTH • HCl were 10^{10.18} and 10^{7.50}, respectively. Therefore, CCs were stronger chelators
7
8
9 158 than PMTH • HCl to form more stable complexes with Cu²⁺, resulting in the fluorescence signal of
10
11 159 PMTH • HCl turn on.

12
13
14 160 When the molar ratio between CCs and Cu²⁺ was 1:1, the fluorescence recovered efficiency
15
16 161 was maximum. The recovered fluorescence was stable. The fluorescence recovered linearly by the
17
18
19 162 CCs concentration within the range of 1.0×10⁻⁸ to 9.0×10⁻⁶ mol/L (n = 5). The equation of the
20
21 163 calibration curve was $\Delta I = 79.615 + 11.496 c / (\mu\text{mol/L})$, r = 0.9968, $\Delta I = I_0 - I$, where I₀ and I were
22
23
24 164 the fluorescence intensity before and after the addition of CCs, respectively. Based on S/N = 3, a
25
26 165 limit of detection (3.34×10⁻⁹ mol/L) was obtained.

27 28 29 166 *3.3 Optimization of experimental condition*

30
31 167 Due to hydroxyl existing in structure of CCs, pH has a great influence on sensitivity of the
32
33
34 168 fluorescence “off-on” switch system. When pH was less than 4, the fluorescence of PMTH • HCl
35
36 169 could not be quenched by Cu²⁺ or stable complexes could not be formed between Cu²⁺ and
37
38
39 170 PMTH • HCl. When pH was more than 9, phenolic hydroxyl could react with base. Meanwhile,
40
41 171 Cu²⁺ can catalyze the oxidation of CCs. The fluorescence intensity achieved maximum in the
42
43
44 172 range of 7.2 to 8.6. The optimum pH 7.8 can be used in all subsequent experiments.

45
46 173 In order to achieve optimal fluorescence efficiency, the incubation time and temperature play
47
48
49 174 important roles in designing the fluorescence “off-on” switch system. The fluorescence intensity
50
51 175 achieved maximum value after incubating for 30 min at room temperature. Although the
52
53
54 176 incubation time was shortened after rising temperature, the stable time of the system was
55
56 177 shortened and the operation became complicated. Therefore, 30 min and room temperature were
57
58
59
60

1
2
3
4 178 used as the optimal experimental condition.
5

6 179 *3.4 Specificity of the “off-on” switch system*
7

8
9 180 The specificity of the system was investigated by testing the assay in response to common
10
11 181 ions, different amino acid, starch and sucrose. The concentrations were at least 50 times greater
12
13 182 than that of CCs (4.0×10^{-6} mol/L) under the same conditions. The results (Table 3) demonstrated
14
15 183 that the proposed method could be applied in the detection of CCs with high specificity.
16
17

18
19 184 (Table 3)
20

21 185 *3.5 Application to detection of samples*
22

23
24 186 In order to demonstrate the feasibility of the new fluorescence “off-on” chemodosimeter for
25
26 187 practical analysis, it was used to detect the recovery efficiency of different concentrations of CCs
27
28 188 in real sample, such as human serum by standard addition methods. The recovery efficiency was
29
30 189 in the range of 96.5% -105% and RSD was below 3.02% (Table 4).
31
32

33
34 190 (Table 4)
35

36 191 *3.6 Comparison of methods*
37

38 192 The analytical performance of the fluorescence “off-on” switch system was compared with
39
40 193 the previously reported methods in Table 5. Compared with previous methods, the proposed
41
42 194 method shows relatively higher sensitivity and lower detection limit.
43

44 195 (Table 5)
45

46 196 **4. Conclusion**
47

48
49 197 In summary, an excellent sensitive, specificity and fast detection method for CCs has been
50
51 198 constructed by using PMTH • HCl as a fluorescence “off-on” probe. In the fluorescence “off-on”
52
53 199 switch system, Cu^{2+} was modified with the ligand for binding with PMTH • HCl, resulting in turn
54
55
56 200 off the fluorescence of PMTH • HCl. Addition of CCs led to the recovery of fluorescence based
57
58
59
60

1
2
3
4 201 on the stronger binding affinity between CCs and PMTH • HCl. The fluorescence “off-on” switch
5
6 202 system with the limit of detection as low as 3.34×10^{-9} mol/L provides a sensitized recognition
7
8
9 203 platform for CCs and possesses promising application in sample analysis.

Tables

Table 1 The quenching constant of the interaction between $[\text{Cu}^{2+}]$ and PMTH • HCl at different temperatures.

T / (K)	K / (L/mol)	n	γ
293	3.162×10^7	1.048	0.9988
298	2.505×10^7	1.063	0.9983
303	1.950×10^7	1.078	0.9986

Table 2 Thermodynamic parameters of the Cu^{2+} - PMTH • HCl system.

T / (K)	$\Delta G / (\text{J/mol})$	$\Delta S / (\text{J/mol} \cdot \text{K})$	$\Delta H / (\text{J/mol})$
293	-4.207×10^4	-1.042×10^7	-3.569×10^4
298	-4.221×10^4	-1.067×10^7	-3.569×10^4
303	-4.229×10^4	-1.077×10^7	-3.569×10^4

Table 3 Effects of interferences

interferents	C / (mol/L)	Interference level / (%)
urea	8.0×10^{-4}	1.83
L-histidine	8.0×10^{-4}	1.45
L-serine	8.0×10^{-4}	0.90
Al^{3+}	8.0×10^{-4}	3.78
glucose	4.0×10^{-4}	2.87
sucrose	4.0×10^{-4}	1.63
L-proline	4.0×10^{-4}	0.83
Fe^{3+}	4.0×10^{-4}	1.79
Mn^{2+}	4.0×10^{-4}	4.35
DL-alanine	2.0×10^{-4}	2.94
L-tryptophan	2.0×10^{-4}	4.12
L-arginine	2.0×10^{-4}	1.79
L-cysteine	2.0×10^{-4}	2.57

Table 4 Determination of CCs in real samples ($n = 9$)

Sample	Amount found ($\mu\text{mol/L} \pm \text{RSD}\%$)	Added ($\mu\text{mol/L}$)	Recovered ($\mu\text{mol/L} \pm \text{RSD}\%$)	Recover (%)
Green tea extract 1	2.92 ± 1.56	2.0	5.02 ± 1.06	105.0
		4.0	6.85 ± 1.98	98.25
Green tea extract 2	1.82 ± 1.22	2.0	3.75 ± 1.12	96.5
		4.0	5.93 ± 2.09	102.75
Human serum	0.28 ± 2.26	2.0	2.23 ± 3.02	97.5
		4.0	4.41 ± 1.62	103.25

Table 5 Comparison of analytical parameters for the determination of CCs

Methods	Reagents or condition	Linear range (mol/L)	Detection limit (mol/L)	Reference
fluorimetry	PMTH·HCl	1.0×10^{-8} to 9.0×10^{-6}	3.34×10^{-9}	This paper
electrochemical	multiwalled carbon nanotube paste electrode	1.0×10^{-7} to 2.69×10^{-6}	1.70×10^{-8}	4
electrochemical	ionic liquid, n-octylpyridinium hexafluorophosphate carbon paste electrode	5.0×10^{-7} to 1.25×10^{-5}	1.32×10^{-7}	5
HPLC	monolithic column	1.62×10^{-6} to 2.60×10^{-6}	3.57×10^{-7}	6
HPLC	solid-phase extraction	1.0×10^{-8} to 1.0×10^{-6}	1.0×10^{-7}	7
HPLC	sulfated- β -cyclodextrin	4.06×10^{-6} to 3.25×10^{-4}	3.57×10^{-7}	8
HPLC	liquid chromatography in tandem mass spectrometry	1.09×10^{-8} to 1.379×10^{-6}	2.60×10^{-9}	9
