Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about *Accepted Manuscripts* in the **Information for Authors**.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard <u>Terms & Conditions</u> and the <u>Ethical guidelines</u> still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

COMMUNICATION

Specific antibody-induced fluorescence quenching for direct and labelfree immunoassay

Xin Li^{a,b,c,&} Jiawen Lei ^{a,b,c,&} Peiwu Li ^{a,b,c,d,e,*} Qi Zhang ^{a,b,c,e,*} Liangxiao Zhang ^{a,b,e} Wen Zhang ^{a,b,e} Zhaowei Zhang ^{a,b,e}

⁵ A simple, direct and label-free immunoassay was proposed based on a specific immune binding reaction induced fluorescence quenching of the analyte. Aflatoxin B₁ (AFB₁) was taken as the model analyte, whose intrinsic fluorescence was quenched by the specific anti-AFB₁ monoclonal antibody.
 ¹⁰ This immunoreaction-induced fluorescence quenching was utilized to quantitatively determine AFB₁.

As a rapid, easy and low-cost method, immunoassay is widely used in the analysis of drug metabolites, plant hormones, proteins, microorganisms and other biological interests based on the ¹⁵ specificity and selectivity of antibody reagents generated.¹ The immunoassay methods include labelled and label-free technologies, and the former was rapidly developed in recent years along with the technological progress of labelling materials, such as the enzyme, radiation, fluorescent, luminescent and ²⁰ nanoparticle materials.² These materials improved the sensitivity of the assay by orders of magnitude, which facilitates its largescale use. For example, to determine the highly-toxic metabolite aflatoxin B₁ (AFB₁), the competitive and labelled immunoassay method was widely applied for rapid detection.³ The used marker ²⁵ determines sensitivity of an immunoassay to a large extent but the quality of the used antibody is important as well.

In contrast with labelled ones, label-free technologies, such as immunodiffusion⁴ and FRET⁵, require only one reaction step all over the assay procedure. The label-free method achieves a direct ³⁰ and short-time consuming determination. It showed promise in real-time determination and played an important role in analyzing bio-molecules and monitoring the reactions.⁶

AFB₁, with intrinsic fluorescence, was selected as an analyte to search for a simple, label-free and direct immunoassay. As we ³⁵ have known that the fluorescence immunotechnologies for AFB₁ analysis were based on the fluorescence of labeled materials.⁷

[&] These authors contributed equally to this work.

⁵⁰ However, the intrinsic fluorescence signal of AFB₁ was seldom utilized for immunoassay.⁸

Here we aim to perform AFB₁ determination by scanning and evaluating the intrinsic fluorescence signals of AFB₁ before and after immunoreaction with specific anti-AFB₁ antibodies and ⁵⁵ nonspecific antibodies and proteins. It was unexpectedly found that the intrinsic fluorescence of AFB₁ could be effectively quenched by the specific anti-AFB₁ antibodies. The fluorescence change was shown in Scheme 1, in which the colour intensity around AFB₁ represented its fluorescence intensity.

Scheme 1. Schematic representation of the fluorescence of AFB₁ 70 was quenched by the specific anti-AFB₁ antibody.

To study the selectivity of this antibody-induced fluorescence quenching (AIFQ) phenomenon, the following proteins were utilized to investigate whether they could quench the fluorescence of AFB₁: two anti-AFB₁ monoclonal antibodies (1C11⁹ and 3G1¹⁰, ⁷⁵ whose sensitivities for AFB₁ measured by ELISA are 0.0012 ng/mL and 1.6 ng/mL, respectively), a non-specific monoclonal antibody (1H2, which was specific for ochratoxin A and had no cross-reactivity with AFB₁¹¹), a non-specific polyclonal antibody (pAb, rabbit anti-mouse polyclonal antibody) and nonspecific ⁸⁰ proteins of bovine serum albumin (BSA) and ovalbumin (OVA). For each test, the concentration of AFB₁ was 50 ng/mL and the volume was 1mL. The added amount of each protein was 40 µL in concentration of 1 mg/mL. As shown in Fig. 1, only 1C11 antibody could significantly induce fluorescence quenching and

- ⁸⁵ 79.6% of the fluorescence intensity was quenched. Meanwhile, 3G1 can quench it only by 26.2%. 1H2, pAb, BSA and OVA have no quenching effect. These results indicated that only anti-AFB₁ antibodies could quench its intrinsic fluorescence and different anti-AFB₁ antibodies possessed different quenching
 ⁹⁰ efficiencies. The non-specific antibodies and proteins could not
- induce fluorescence quenching.

According to our previous report,¹² this immunoreactioninduced fluorescence quenching may mainly be attributed to hydrogen bond and hydrophobic interactions formed by the Ser-²⁰ H49 and Phe-H103 of the antibody and the benzene ring and its neighboring furan ring of the AFB₁, which changed the conjugated system of AFB₁. However, two different anti-AFB₁ antibodies have different quenching efficiencies. The detailed quenching mechanism and the cause of this difference are under ²⁵ investigation in our recent study.

In this work, this AIFQ phenomenon was proposed to develop a direct and label-free immune technology for quantitative determination of analytes with intrinsic fluorescence. AFB₁ was employed as a model analyte, and the specific antibody 1C11 was ³⁰ selected in the following experiment. Afterwards, AFB₁ analysis in peanut samples was employed to validate this AIFQ immunoassay method.

With a chain of conjugated bonds and heteroatoms, AFB₁ has intrinsic fluorescence and displays a maximum emission ³⁵ wavelength of ca. 440 nm when excited at 365 nm.¹³ AFB₁ is highly toxic but of a low concentration in food and feedstuff. European Commission has strictly set the maximum limit of AFB₁ to 5 ng/mL.¹⁴ However, the fluorescence intensity of AFB₁ at a low concentration is not high enough. Thus, the fluorescence ⁴⁰ quenching phenomenon is not obvious after the combination reaction with the specific anti-AFB₁ antibody 1C11 (Fig. 2). For 20 ng/mL of AFB₁ standard solution, only 26.6% of the fluorescence was quenched. Then, the limit of detection (LOD) of this AIFQ immune method used for AFB₁ detection is of a high ⁴⁵ level and the method possesses a low sensitivity.

In order to improve the sensitivity of this method, the fluorescence intensity of the initial AFB₁ solution was enhanced. As reported in previous studies, β-cyclodextrin, 2, 6-Di-Omethyl-β-cyclodextrin and other fluorescence enhancers were ⁵⁰ used to enhance fluorescence signals.¹⁵ In this study, 2, 6-Di-Omethyl-β-cyclodextrin was used to increase the fluorescence strength of AFB₁, making the quenching phenomenon more obvious. The substantial enhancement of the fluorescence emission of aflatoxins with an unsaturated furan ring in the ⁵⁵ presence of aqueous solutions of 2, 6-Di-O-methyl-βcyclodextrin is well known. In addition, there are several applications described to use these host-guest inclusion complexes for mycotoxin determination. The changes, i.e., an enhancement of the mycotoxin fluorescence upon inclusion, can ⁶⁰ be understood being a result of induced significant changes in the physical and chemical properties of AFB₁ as guest molecule. The fluorescence intensity was significantly enhanced with the presence of the enhancer (Scheme 1).

AFB, of 20 ng/mL in 10% methanol-water

Fig. 2 Fluorescence of AFB₁ at ca. 440 nm when excited at 365 nm, before and after the immunoreaction with 20 μL 1C11 of 1 ⁸⁰ mg/mL, using and not using a fluorescence enhancer (2, 6-Di-O-methyl-β-cyclodextrin).

The results in Fig. 2 indicated that the fluorescence intensity at 440 nm was enhanced 4.3 times. After the immune reaction with 1C11, 80.1% of the enhanced fluorescence of AFB₁ was ⁸⁵ quenched. Meanwhile, the maximum fluorescence wavelength for AFB₁ remains unchanged (Supporting Information, Fig. S1).

To employ this method in AFB₁ analysis in real samples, some organic solvents were used in the sample extraction process and these solvents were evaluated to study their effects on 90 fluorescence detection. The extraction of AFB1 in food and feedstuff is normally performed with 70% (v/v) methanol-water. As high concentration of methanol and other organic solvents may affect the activity of the antibody, the methanol concentration was optimized to minimize the effect on the 95 antibody activity. The evaluation results of 10% and 20% methanol-water indicated that 10% methanol had less negative effect on the antibody than 20% methanol. Therefore, AFB₁ dissolved in 10% (v/v) methanol-water was used for further experiments. The fluorescence of AFB1 was enhanced by adding 100 2, 6-Di-O-methyl-β-cyclodextrin, and then the specific anti-AFB₁ antibody 1C11 was added into the mixture to perform immunoreaction. The fluorescence scanning results validated that the fluorescence intensity of AFB₁ decreased sharply after the immunoreaction with 1C11 in the solvent of 10% (v/v) methanol-105 water.

To obtain an apparent quenching phenomenon and the highest utilization efficiency of 1C11, the amount of 1C11 was optimized. Serial amounts of 1C11 were added into the mixture of AFB₁ (20 ng/mL, 1 mL) and 2, 6-Di-O-methyl-β-cyclodextrin (0.01 mol/L, 500 µL). After the immunoreaction, the fluorescence of the products was measured. The results in Fig. 3 indicated that 10-200 µg 1C11 showed similar quenching efficiencies. Therefore, 10 µg was used for immunoreaction to save cost. According to the molecular weights of AFB₁ and the monoclonal antibody, the

60

65

number of molecules of AFB_1 can be calculated, which equals to that of the mAb. The results indicated that each mAb could only react with one molecule of AFB_1 , and after the AFB_1 reacted with the antibody, the fluorescence of AFB_1 was quenched.

Fig. 3 Optimization of the amount of the anti-AFB₁ antibody 1C11.

To shorten the detection procedure, the quenching efficiencies after different reaction time were studied. The fluorescence of the mixture of AFB₁, the enhancer and the 1C11 antibody was scanned after reaction of 3, 5, 8, 15, 20, 30, 40, 50 and 60 min, respectively. The results in Fig. 4 demonstrated that this antibody could quench most of fluorescence in 3 min. Along with the increase of the reaction time, the quenching efficiency weakly increased. At 15 min, the reaction was almost complete and showed acceptable fluorescence quenching efficiency within the shortest analysis time. Therefore, the reaction time of 15 min was o chosen as the optimal time parameter.

Based on the optimized parameters, this direct and label-free immune technology was used to quantitatively analyze AFB₁. For AFB₁ standard solutions of 0.1, 0.2, 0.5, 1, 2, 5, 10 and 20 ng/mL, the fluorescence intensities before and after the immunoreaction ⁵⁰ with 1C11 were detected for 10 times separately. The intensity values at 440 nm were shown in Fig. S2 (Supporting Information). Then, a standard quenching curve for AFB₁ standard solution was established. As shown in Fig. 5, the calibration curve showed good linearity ($r^2 = 0.9998$) for AFB₁ from 1 ng/mL to 20 ng/mL. ⁵⁵ The LOD for AFB₁ was determined as 0.35 ng/mL, calculated by adding three times the signal-to-noise ratio to the background value.

⁷⁰ **Fig. 5** A standard curve of the quenched fluorescence intensity for different concentrations of the AFB₁ standard, y = 33.67x + 13.68, $r^2 = 0.9998$, n = 10.

This suggests a sensitive and easy method for AFB₁ analysis. Moreover, this method enables fluorescence quenching with ⁷⁵ specific antibodies and could overcome the interference from other materials that give similar fluorescence signals. On one hand, this method is significantly simple and time-saving compared with conventional immunoassay methods. On the other hand, this method is environmentally-benign as it does not need ⁸⁰ highly toxic antigens, which is also friendly to operators and reduces detection costs.

To investigate the matrix effects of the samples on the quantitative analysis, AFB_1 in real food sample extraction was studied by this AIFQ method. The AFB_1 -free peanut sample was so first validated by HPLC. Then, 20 g blank sample was extracted with 50 mJ 70% (y(y)) methods have a single for 2 min. But

- with 50 mL 70% (v/v) methanol-water by grinding for 2 min. By filtrating with double filter paper, the filtrate was collected in a 50 mL tube, and cleaned twice with the alumina column to alleviate the matrix effect of the peanut. The product was spiked with
- ⁹⁰ AFB₁ standard solution and then diluted with water until the final proportion of methanol was 10% and AFB₁ was of the serial concentrations of 0, 0.1, 0.2, 0.5, 1, 2, 5, 10 and 20 ng/mL. The fluorescence quenching experiments were performed in the above optimized conditions and the fluorescence of AFB₁ spiking ⁹⁵ solutions was measured. The evaluation results indicated that the fluorescence quenching was obvious even with the presence of the sample matrix. For fluorescence intensities of serial concentrations of AFB₁, a calibration curve (y = 35.95x + 69.63, $r^2 = 0.9959$) similar to the curve in Figure 5 was also obtained, ¹⁰⁰ which showed good linearity ($r^2 = 0.9959$) from 1 ng/mL to 20
- ng/mL (Supporting Information, Figure S3). The results demonstrated that this method could successfully overcome the matrix effects of real samples and could be employed in accurate determination of AFB_1 in the peanut samples.

¹⁰⁵ To study the application of this AIFQ mothod, the AFB₁ spiked peanut samples were detected with this method. Meanwhile, these samples were detected with HPLC method for validation. The AFB₁-free peanut sample was spiked with AFB₁ at the concentrations of 10, 20 and 50 µg/kg and then was kept at room ¹¹⁰ temperature overnight. These samples' pre-treatment for AIFQ method was the same as the above sample preparation process. The samples' pre-treatment for HPLC detection was according to the reported method.¹⁶ The results obtained by AIFQ and HPLC assay were summarized in Table 1. These results indicated that ¹¹⁵ the recoveries of AIFQ method were consistent with those from ¹¹⁰

HPLC, showing good application of this AIFQ method in peanut sample analysis. The LOD value of this AIFQ method is not high enough, which may be caused by the fluorescence detector's low resolution. The research on improving the sensitivity will be s further studied in the following study.

Conclusions

10 In summary, we proposed a novel label-free immunoassay method based on specific immunoreaction fluorescence quenching, using AFB₁ as an example analyte. This method was applied to perform the detection of AFB1 in peanut samples and the results indicated that the method could be successfully used to ¹⁵ analyze AFB₁ in the complex sample matrix. During the assay, AFB₁ could be specially recognized by its corresponding antibody, which induces a fluorescence quenching phenomenon on AFB₁. The other specific antibodies and proteins, however, cannot react with AFB₁ so as to induce fluorescence quenching. 20 In a direct and label-free way, this fluorescence quenching phenomenon on the target analyte with intrinsic fluorescence signals could be widely employed in determination of AFB₁ and other analytes. This method is easy, fast, low-cost and friendly to operators and the environment. Nevertheless, it is only suitable 25 for the target with intrinsic fluorescence and only specific antibodies could effectively quench the fluorescence. The preparation of specific and sensitive antibodies is essential and very important, which could be obtained by the monoclonal and recombinant antibody technology. The study on the detailed 30 fluorescence quenching mechanism could provide guidance for the production of recombinant antibody. Moreover, the equipment with a higher resolution could be utilized to obtain much higher distinguish ability and better sensitivity.
