Rapid fluorescence spectroscopic screening method for sensitive detection of thiabendazole in red wine

Abstract

In this work, a rapid, sensitive, reliable and cost-effective fluorescence spectroscopic method has been established for detection of thiabendazole (TBZ) in red wine based on second-derivative constant-wavelength synchronous fluorescence spectroscopy (DCWSFS) coupled with ultrasound-assisted liquid-liquid extraction technique. The constant wavelength difference ($\Delta\lambda$) was set at 50 nm between excitation and emission monochromators. Compared with UV-Vis absorption spectroscopy and conventional fluorescence spectroscopy, this method has the advantages in improving spectral resolution and eliminating the interference of spectral background from red wine. This method avoided the requirements of complicated purification and pretreatment procedures. The detection of TBZ is free from the interference of co-existence pesticides, demonstrating the high selectivity of this method. Satisfactory recoveries of the spiked red wine samples were obtained ranging from 85.9 to 102.8 %. The calibration curve showed good linearity in a range from 0.05 to 1.0 $\mu\text{g/mL}$ for TBZ. The detection limit ($S/N=3$) was 7.2 ng/mL and the relative standard deviation ($n=5$) value was 3.9 %. The results obtained by this method for analyzing TBZ in red wine samples correlated well with those obtained by HPLC method. This method would be an attractive alternative for rapid screening of TBZ in large amounts of samples.

7 **Introduction**
8

9
10 Red wine has been one of the most popularly consumed drinks in the world. It has
11 shown good health-care effect on anti-aging, weight loss, beauty and its prevention
12 and cure of different diseases such as cardiovascular disease, cerebral thrombosis and
13 cancer ^{1, 2}. However, pesticides are commonly used to treat pests and diseases of
14 grapes in vineyard, which may cause pesticide residues in grapes and thus may induce
15 the residues in wine through the wine-making process. As a result, pesticide residue is
16 quite a potential health threat to people through wine consumption ^{3,4}.

25
26

27 Benzimidazole fungicides are effective pesticides and extensively applied for the
28 pre- or post-harvest treatment of a great variety of crop diseases caused by various
29 fungi. Thiabendazole (2-(4-thiazolyl) benzimidazole, TBZ) is one of the most widely
30 used compounds to treat crop diseases such as mold, rot, blight and stain ⁵. After
31 treating crops and then entering the environment, pesticides can be transported in
32 air-soil-water-plant systems and may be absorbed by plant tissues and then exist in
33 fruits and vegetables or their processed products. Most of the fungicides cause severe
34 damage to human health and their residues have been found to be very persistent in
35 water, soil, crops and food for quite a long time ⁶⁻¹⁰. In order to prevent consumers
36 suffering from noxious pesticide damage, maximum residue levels (MRLs) have been
37 established by the European Union (EU) and the Codex Alimentarius Commission
38 (CAC) for a great quantity of pesticide residues in food ¹¹⁻¹³. Therefore, it is of great
39 significance to determine pesticide residues in wine.

1
2
3
4 Common analytical methods used for the determination of benzimidazole
5
6 fungicides include high-performance liquid chromatography with ultraviolet or
7
8 fluorescence detection (HPLC-UV/FLD) ¹⁴ and liquid chromatography with mass
9
10 spectrometry (LC-MS) ¹⁵. For above analyses, the samples were first extracted with
11
12 methanol, acetonitrile or dichloromethane, and then the extract was purified on
13
14 different kinds of solid phase absorption column. Fractions eluted from the columns
15
16 were subsequently measured by HPLC-UV/FLD or LC-MS. These techniques often
17
18 consume large volumes of toxic organic solvent, especially in pre-separation and
19
20 clean-up procedures and they are extremely time-costing and labor-consuming.
21
22 Moreover, the maintenance of HPLC-UV/FLD or LC-MS is complicated and costly.
23
24 These disadvantages restrict the development of rapid determination of benzimidazol
25
26 fungicides in food samples. Therefore, it is indispensable to establish a rapid, reliable,
27
28 and cost-effective method for evaluating and screening thiabendazole in food.

29
30
31 Since benzimidazol fungicides exhibits native fluorescence, highly sensitive
32
33 fluorescence method coupled with sequential injection analysis or chemometrics has
34
35 been proposed for determination of thiabendazole in mushroom sample ¹⁶ or
36
37 environmental samples ^{17, 18}. Fluorescence method also has been used as the detection
38
39 technique in HPLC method ¹⁹. HPLC ²⁰ and capillary electrophoresis ²¹ have already
40
41 been proposed for determination of thiabendazole in grape or wine. However, to the
42
43 best of our knowledge, there has been no report on a fluorescence spectroscopic
44
45 method for direct detection of thiabendazole in red wine samples without resorting to
46
47 chromatographic separation and purification procedures. Because the emission

1
2
3
4 spectrum obtained from the conventional fluorescence spectroscopy commonly
5
6 suffers from light scattering interference and broad-band fluorescence features, it is
7
8 still hard to utilize conventional fluorescence spectroscopy in this study.
9

10
11 Compared with the conventional fluorescence spectroscopy, synchronous
12
13 fluorometric method can overcome the light scattering interference, narrow the broad
14
15 band fluorescence features, simplify the spectrum and improve the selectivity and the
16
17 spectral resolution of fluorescence spectroscopy²²⁻²³. Constant-wavelength
18
19 synchronous fluorescence spectroscopy (CWSFS) is quite commonly used, which is
20
21 achieved by maintaining a constant wavelength-difference $\Delta\lambda$ ($\Delta\lambda = \lambda_{em} - \lambda_{ex}$) between
22
23 excitation and emission monochromators²⁴. According to the scanning speeds and the
24
25 wavelength differences between excitation and emission monochromators, several
26
27 other synchronous fluorescence methods have been developed, including
28
29 constant-energy synchronous spectroscopy (CESFS), variable-angle synchronous
30
31 fluorescence spectroscopy (VASFS) and matrix-isopotential synchronous fluorescence
32
33 spectroscopy (MISFS)²⁵⁻²⁹. Besides, based on the ability in narrowing band and
34
35 amplifying minor spectral features, derivative technique has been extensively applied
36
37 in analytical chemistry to effectively enhance the sensitivity and reduce the
38
39 background or matrix interference^{30, 31}. The incorporation of synchronous
40
41 fluorescence spectroscopy and derivative technique shows synergetic effects and can
42
43 further improve the sensitivity and the selectivity in contrast to the conventional
44
45 fluorescence spectroscopy³². The incorporated technique can play a critical role in
46
47 separating the overlapping spectrum without the request of complicated physical
48

1
2
3
4 pre-treatment procedures. It has been widely applied to determine analytes in complex
5
6 matrices^{33, 34}.
7

8
9 The matrix of the red wine sample is extremely complex due to the existence of
10
11 phenolic compounds, pigments, sugar, organic acids, vitamin, mineral element, amino
12
13 acids and other unknown components, which has a great influence on the accurate
14
15 analysis of TBZ. In general, a series of purification and pre-separation processes are
16
17 required before instrumental analysis, which naturally make the entire analysis
18
19 process more tedious and time-consuming. Based on the obvious synergistic effects
20
21 between synchronous fluorescence spectroscopy and derivative technique, this
22
23 method can effectually overcome matrices or background interference of red wine
24
25 samples and largely simplify sample pretreatment process without resorting to
26
27 complicated purification and chromatographic separation procedures.
28
29
30
31
32

33
34 The aim of this work was to develop a rapid, simple, reliable and sensitive
35
36 fluorescence spectroscopic method for detection of thiabendazole in red wine. Based
37
38 on second-order derivative constant-wavelength synchronous fluorescence
39
40 spectroscopy (DCWSFS), high sensitivity and selectivity have been achieved.
41
42 Complicated chromatographic separation and purification procedures were avoided in
43
44 the sample preparation and the entire analysis time was greatly shortened to about half
45
46 an hour. This approach has been used for detection of TBZ in different brands of red
47
48 wine samples. Spiked recovery tests were carried out for validation, with average
49
50 recovery values between 85.9 and 102.8 %. This method was compared with HPLC
51
52 method to further confirm the analytical power of the proposed approach.

Experimental

Materials and reagents

Thiabendazole standard (purity $\geq 99.9\%$) was obtained from J&K Scientific Ltd. (China). 100.0 mg/L thiabendazole-methanol stock solution was prepared in 25.0 mL brown volumetric flask. This solution was stored at 4 °C to avoid exposure to direct light. The solutions of lower concentrations were prepared by properly diluting the stock solution with methanol. Methanol (HPLC grade) and the other solvents (analytical grade) were purchased from Shanghai Reagent (China). Ultrapure water was acquired by a Millipore Milli-Q water purification system.

Apparatus

All synchronous fluorescence spectra were achieved on a laboratory-constructed, computer-controlled spectrofluorometer, which was provided with a 150 W xenon lamp. The slit band passes were set at 5 nm for both excitation and emission monochromators, which were commanded by a computer via a program package written in Turbo C 2.0³⁵. The data of synchronous fluorescence spectra were obtained by the computer through the program package. The second-order derivative synchronous fluorescence spectra were directly recorded by an electronic differentiator system attached to the spectrofluorometer. Besides the common fluorescent excitation and emission spectra, the instrument supplies all kinds of synchronous fluorescence spectra, including constant-wavelength, constant-energy, variable-angle and matrix-isopotential synchronous spectra. This instrument was applied successfully in previously reported work³⁶⁻³⁸. A UV-Visible

1
2
3 spectrophotometer (U-3900, Hitachi, Japan) was used to obtain the spectra and
4
5
6 methanol was used for baseline measurement. HPLC analysis was completed on a
7
8
9 Shimadzu LC-15C system equipped with a Shimadzu RF-20A fluorescence detector
10
11 (Shimadzu (China) co. Ltd., Shanghai Branch, Shanghai, China). The ultrasonic
12
13 extraction procedure was performed on an ultrasonic cleaner (Ningbo Xinzhi
14
15 Biotechnology Co., Ltd., Ningbo, China) and the rotary evaporator (YRE-52 C) was
16
17 purchased from Gongyi Yuhua instrument Co., Ltd., Henan, China.
18
19
20

21 22 Sample preparation

23
24 The analyzed red wine samples were purchased in the supermarket and they were kept
25
26 at 4 °C avoiding exposure to direct light. 1.0 mL of red wine was put into a 100 mL
27
28 volumetric flask, to which 2.0 mL ultrapure water was added. This aqueous phase was
29
30 extracted with 8.0 mL of dichloromethane in an ultrasonic cleaner for 8 min. The
31
32 lower organic phase was separated and collected. This process was repeated in
33
34 duplicate. All organic extracts were combined and then evaporated to dryness by a
35
36 rotary evaporator at 35 °C water bath. The residue was re-dissolved with 5.0 mL of
37
38 methanol.
39
40
41
42
43
44

45 46 Analysis of TBZ

47
48 2 mL of the extract was poured into a 1×1 cm quartz cuvette and then measured by
49
50 spectrofluorometer. All synchronous fluorescence spectra were recorded by
51
52 spectrofluorometer with a 50 nm wavelength-difference ($\Delta\lambda$) between excitation and
53
54 emission monochromators at a scan speed of 240 nm min⁻¹ and the emission
55
56
57
58
59
60

1
2
3
4 wavelength ranging from 330 to 480 nm, by which the second-order derivative
5
6 fluorescence spectra were obtained within one minute. Second-order derivative
7
8 synchronous spectra were recorded by the electronic differential system attached to
9
10 the spectrofluorometer. The continuous standard addition method which could
11
12 overcome the possible matrix effects was applied to calculate the concentration of
13
14 TBZ in the red wine extracts. Calibration curve was obtained by continuous addition
15
16 of TBZ standard solution to red wine extract. All experiments were completed at
17
18 ambient temperature.
19
20
21
22
23

24 25 Method validation

26
27 In order to validate the accuracy of this method, the results obtained by DCWSFS
28
29 were compared with those obtained by HPLC method. HPLC analysis was completed
30
31 on a Shimadzu LC-15C system equipped with a Shimadzu RF-20A fluorescence
32
33 detector. The excitation and emission wavelength for analyzing TBZ were set at 305
34
35 nm and 345 nm, respectively. A Diamonsil-C18 column (250 mm×4.6 mm ×5 μm,
36
37 Dikma, China) was applied at room temperature. The isocratic mobile phase was
38
39 composed of methanol-water (50:50, v/v) at a total flow rate of 0.8 mL/min. The
40
41 elution conditions of HPLC method was adapted on the basis of reference method ³⁹.
42
43
44
45
46 The injection volume was 20 μL.
47
48
49
50

51 **Results and Discussion**

52 Spectra analysis of thiabendazole and wine sample

53
54
55
56 Because red wine contains large amounts of pigment and other unknown fluorescence
57
58
59
60

1
2
3
4 compounds, serious matrix effect exists in the extract after simple extraction. In order
5
6 to further eliminate the interference of spectral background from red wine and to
7
8 propose a suitable method for direct accurate analysis of TBZ in wine extract,
9
10 different spectroscopic methods were investigated, including UV-Vis absorption
11
12 spectroscopy, conventional fluorescence spectroscopy and constant-wavelength
13
14 synchronous fluorescence spectroscopy. As shown in Fig. 1a, the absorption bands of
15
16 TBZ and blank wine sample were extremely overlapped and high background signal
17
18 was observed in red wine located at about 300 nm. Direct quantitative analysis of
19
20 TBZ in wine extract was impossible by using UV-Vis absorption spectroscopy. Fig. 1b
21
22 showed the conventional fluorescence emission spectra of TBZ and blank wine
23
24 sample; TBZ exhibits a broad emission peak located at about 355~365 nm in
25
26 methanol with an excitation maxima located at 315 nm and the blank wine sample
27
28 showed an extremely wide background interference peak located at about 390~450
29
30 nm. The emission spectrum of spiked wine sample indicated that the emission peak of
31
32 TBZ was still dramatically interfered by the spectral background of red wine. It was
33
34 still a challenge to eliminate the spectral background interference and achieve direct
35
36 accurate quantitative analysis of TBZ by conventional fluorescence spectroscopy.
37
38 Herein, in order to eliminate spectral background interference and obtain a narrower
39
40 band of TBZ for accurate analysis, we proposed a constant-wavelength synchronous
41
42 fluorescence spectroscopic approach in this work. To achieve the synchronous
43
44 fluorescence spectra, a value of 50 nm was selected as the optimum wavelength
45
46 difference ($\Delta\lambda$) between excitation and emission monochromators because this value
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 is close to the Stokes shift of TBZ and TBZ exhibits its highest fluorescence signal at
5
6 this wavelength difference. In the case of synchronous fluorescence spectra (Fig.2a),
7
8 the synchronous fluorescence peak of TBZ in spiked wine sample was obviously
9
10 narrowed and more prominent in contrast to its conventional fluorescence emission
11
12 peak (Fig.1b). As shown in Fig.2b, the peak of TBZ was further narrowed
13
14 accompanied with intensity greatly improved while synchronous fluorescence method
15
16 was combined with second-order derivative technique owing to the obvious
17
18 synergistic effect between them. The original small peak of TBZ was further enlarged
19
20 by using second-order derivative technique, which was advantageous to quantification
21
22 and could effectively improve the sensitivity of the measurement. Besides, this
23
24 derivative synchronous technique reduced the interference from other fluorescent
25
26 compounds existing in red wine sample and eliminated spectral background
27
28 interference exclusively (Fig.2b, black line). Compared with UV-Vis absorbance
29
30 spectroscopy and conventional fluorescence emission spectroscopy, second-order
31
32 derivative constant-wavelength synchronous spectrofluorometry provided a method to
33
34 measure directly TBZ in red wine samples without complicated pre-treatment
35
36 processes.
37
38
39
40
41
42
43
44
45

46 The matrix of red wine sample is extremely complex due to the existence of
47
48 pigments, phenolic compounds and other unknown components. As shown in Fig.2a,
49
50 there was a wide interference peak of other fluorescence compounds located at about
51
52 430 nm in wine sample, whose shape and signal intensity almost remained consistent
53
54 for different brands of red wine samples according to our study, which may produce a
55
56
57
58
59
60

1
2
3
4 similar matrix effect in different wine samples. The complicated matrices of red wine
5
6 sample may create serious matrix effect to induce the fluorescence quenching of TBZ.
7
8 As shown in Fig.3, due to the existence of the matrix effect, the slope of calibration
9
10 equation of TBZ in wine sample ($S=899.6$) was smaller than that in pure methanol
11
12 solvent ($S=1310.3$). Although the incorporation of derivative technique can eliminate
13
14 the interference of spectral background signal, it can not eliminate the influence on
15
16 measurement sensitivity. Besides, in order to further eliminate the matrix effect on the
17
18 measurement sensitivity, the continuous standard addition method was used and
19
20 performed by continuously spiking approximate concentration of TBZ standard
21
22 solution into the red wine extract for four times to match matrices of red wine. And
23
24 the quantification of TBZ was achieved by measuring its peak-valley height, which
25
26 exactly matched the height between the maximum at 365 nm and the consecutive
27
28 minimum at 376 nm at second-order derivative synchronous spectra (Fig.2b).
29
30
31
32
33
34
35
36

37 Selection of spectral analysis solvent

38
39 The influences of four solvents (methanol, dichloromethane, acetonitrile and ethyl
40
41 acetate) on the fluorescence of TBZ were investigated in the corresponding optimum
42
43 values of $\Delta\lambda$. As shown in Fig.4a, pure ethyl acetate exhibited its solvent interference
44
45 peak located in about 350~390 nm, which overlapped seriously with the second-order
46
47 derivative spectra of TBZ and influenced the fluorescence signal of TBZ. Therefore,
48
49 ethyl acetate was not suitable for analyzing TBZ. The spectra of other three solvents
50
51 had no significant influence on the spectra of TBZ. Fig.4b showed the second-order
52
53 derivative synchronous spectra of the TBZ standard solution, the results indicated that
54
55
56
57
58
59
60

1
2
3
4 TBZ exhibited higher fluorescence intensity in methanol than that in other two
5
6 solvents. So methanol was selected as spectral analysis solvent for TBZ to further
7
8 improve measurement sensitivity since the fluorescence intensity of TBZ in methanol
9
10 is the highest.
11
12

13 14 15 Optimization of extraction conditions 16

17
18 In order to obtain the optimal extraction efficiency of TBZ, major factors including
19
20 the selection of extraction solvent, the volume of extraction solvent and extraction
21
22 time were investigated. Experiments were performed with 1 mL red wine sample
23
24 spiked with 0.5 $\mu\text{g/mL}$ of TBZ. Parameters were maintained constant except the
25
26 tested one and all experiments were completed at ambient temperature.
27
28
29
30

31 32 Selection of extraction solvent 33

34
35 The extraction solvent is one of the major factors that affect the extraction efficiency
36
37 of the target compound. In this work, the commonly used organic solvents in
38
39 laboratory have been investigated, including acetonitrile, methanol, acetone,
40
41 dimethylsulfoxide, tetrahydrofuran, ethyl acetate, dichloromethane and
42
43 hexamethylene. When acetonitrile, methanol, acetone, dimethylsulfoxide and
44
45 tetrahydrofuran were selected as extract solvent, wine-water phase and organic phase
46
47 dissolved each other, the organic phase was difficult to be thoroughly separated from
48
49 mixtures even with the help of centrifugal machine and the organic extract was so
50
51 deeply red to cause serious matrix effects. However, when dichloromethane, ethyl
52
53 acetate and hexamethylene were selected as extract solvent, organic phase can be
54
55
56
57
58
59
60

1
2
3 automatically separated from the wine-water phase and there was no red pigment
4
5
6 dissolving in organic solvents to further reduce matrix interference. The results shown
7
8
9 in Fig.5 indicated that dichloromethane showed the best extraction efficiency, and
10
11 hexamethylene showed the worst, because hexamethylene showed bad solubility for
12
13 TBZ and resulted in low extraction efficiency of TBZ. Therefore, dichloromethane
14
15 was selected as the extraction solvent.
16
17
18
19

20 Effect of volume of dichloromethane

21
22 To achieve satisfactory recovery of TBZ, different volumes of dichloromethane (2, 4,
23
24 6, 8, 10 and 12 mL) were investigated and the results were shown in Fig.6a. The
25
26 recovery increased as the volume of dichloromethane increased from 2 to 8 mL.
27
28 When the volume of dichloromethane further increased over 8 mL, there was a clear
29
30 decrease of extraction efficiency, which may be owing to the increasing of the matrix
31
32 effect caused by the co-extraction from red wine sample with larger volume of
33
34 extraction solvent. Thus, 8 mL of dichloromethane was selected as the optimal
35
36 volume.
37
38
39
40
41
42

43 Effect of extraction time

44
45 The effect of the extraction time was investigated from 2 to 12 min (Fig.6b). The
46
47 results indicated that the recovery increased as the extraction time increased from 2 to
48
49 12 min. And there was no distinct increase to the recovery of TBZ when extraction
50
51 time further increased over 8 min. Therefore, 8 min was considered to be the optimal
52
53 extraction time in the following work. And the extraction procedure satisfied the
54
55
56
57
58
59
60

1
2
3
4 requirement of rapid extraction.
5
6

7 Analytical features of the proposed method

8
9
10 The calibration curve was performed by plotting the peak-valley height of the
11 second-order derivative synchronous fluorescence intensity of TBZ versus its
12 corresponding concentration. As shown in Table 1, the calibration equation was
13 calculated as $I=48.4+908.6C$ in the range of 0.05-1.0 $\mu\text{g/mL}$ with correlation
14 coefficient higher than 0.99. The limits of detection and quantification of the proposed
15 method were calculated via the analysis of a blank red wine sample ($n=11$). The blank
16 red wine sample was found to have no detectable concentration of TBZ utilizing the
17 proposed method. As shown in Table 1, the detection limit (LOD) and quantification
18 limit (LOQ) of TBZ, defined as $3\text{ SD}/k$ and $10\text{ SD}/k$, were 7.2 ng/mL and 23.9 ng/mL ,
19 respectively, where SD was the standard derivation of the 11 blank signals and k was
20 the slope of the calibration equation. The precision of this method was further
21 assessed by the application of the proposed method for analysing TBZ in a spiked red
22 wine sample (spiked with 0.5 $\mu\text{g/mL}$ of TBZ, $n=5$) and the relative standard deviation
23 value was 3.9 %, demonstrating a good precision of the proposed method.

43
44

45
46 Method validation

47
48 The level of TBZ was not detected in real red wine samples by the proposed method.
49
50 A spiked recovery experiment was performed to estimate the accuracy of the
51 proposed method. The recovery tests were performed by utilizing the whole processes
52 (extraction and measurement) to different brands of wine samples, to which different
53
54
55
56
57
58
59
60

1
2
3
4 amounts of TBZ had been added. The extract was then determined by both the
5
6 proposed method and the HPLC method. As shown in Table 2, the recoveries of TBZ
7
8 obtained by the proposed method ranged from 85.9 to 102.8 % with relative standard
9
10 deviation (RSD, n=3) between 1.8 and 7.8 %. The results acquired by the HPLC
11
12 method have also been shown in Table 2. The results obtained by these two methods
13
14 correlated well, which further confirmed the accuracy and feasibility of the proposed
15
16 method.
17
18
19

20 21 22 Interference study

23
24 In order to evaluate the availability of this method for the determination of TBZ in
25
26 real samples, other interfering pesticides which could tend to coexist in real samples
27
28 were added to 0.5 µg/mL thiabendazole standard solution and their effect on the
29
30 fluorescence signal of TBZ was then tested. Common pesticides, which are widely
31
32 used and may be formulated along with thiabendazole such as imazalil, were
33
34 investigated. The results were shown in Table 3. The tolerance concentration was
35
36 greater than 50 µg/mL for benomyl, carbendazim, imazalil, procymidone, and 10
37
38 µg/mL for thiophanate-methyl when the level of thiabendazole was 0.5 µg/mL in their
39
40 mixture standard solution. It can be concluded that thiabendazole can be determined
41
42 in the existence of higher concentrations of possibly interfering pesticides in real
43
44 samples.

52 53 **Conclusions**

54
55
56 In this work, a rapid, simple, sensitive and economic fluorescence spectroscopic
57
58
59
60

1
2
3
4 method was developed for the detection of TBZ in red wine samples with simple
5
6 pretreatment procedures. The entire analysis process including extraction and
7
8 determination was simplified and accomplished in a short time (less than 0.5 h),
9
10 which was in a contrast to complicated chromatographic separation and purification
11
12 procedures. Based on the obvious synergistic effect between synchronous
13
14 fluorescence spectroscopy and derivative technique, this method can effectively
15
16 enhance the spectral resolution and eliminate the matrix interference of red wine. The
17
18 selective analysis of TBZ was achieved even when possibly interfering pesticides in
19
20 real samples are present with higher concentrations. The comparisons between this
21
22 method and HPLC method in spiked red wine samples further validated the analytical
23
24 power of the proposed approach. This method would be an attractive alternative for
25
26 rapid screening of TBZ in large amounts of samples.
