## On-line micelle to solvent stacking in capillary electrophoresis for the preconcentration of three antihistamines from human plasma

Xiumin Yang, Shujing Liu, Chun Wang, Zhi Wang\*

Department of Chemistry, College of Science, Agricultural University of Hebei,

Baoding 071001, China

Electropherograms of blank human plasma (A) and human plasma spiked at  $2.0 \mu\text{g mL}^{-1}$  each of the antihistamines and  $4.0 \mu\text{g mL}^{-1}$  IS (B). The insert was the zoomed electropherogram of the main part of the electropherogram B. Peak identification: 1 – palmatine (IS), 2 – diphenhydramine, 3 – chlorpheniramine, 4 – promethazine, U – unknown.

**Abstract**

A new on-line concentration method of micelle to solvent stacking in capillary electrophoresis was developed for the determination of three antihistamine drugs (chlorpheniramine, diphenhydramine and promethazine) in human plasma. Palmatine was used as an internal standard. The main parameters that affect the separation and detection sensitivity of the method were investigated and optimized. Under the optimized conditions, the sensitivity enhancement factors obtained by the developed method for diphenhydramine, chlorpheniramine and promethazine were 63, 43 and 111, respectively. The method showed a good linearity in the range of 0.6-60.0  $\mu\text{g mL}^{-1}$  for the three antihistamines with the correlation coefficients varying from 0.9971 to 0.9996. The limits of detection ( $S/N = 3$ ) were 0.1-0.2  $\mu\text{g mL}^{-1}$ . The relative standard deviations for intra-day ( $n = 8$ ) and inter-day ( $n = 5$ ) analysis were found to be less than 9.1%. The recoveries of the method for the analytes were in the range from 89.7% to 108.0%. The method is feasible for fast screening of the antihistamine drugs in plasma.

**Keywords:** Capillary electrophoresis; Micelle to solvent stacking; Antihistamine; Plasma

## 21 Introduction

22 The antihistamine drugs are mainly used to treat seasonal allergic rhinitis, urticaria, pruritus, and  
23 insect bites and stings caused by excessive release of histamine.<sup>1</sup> Diphenhydramine,  
24 chlorpheniramine and promethazine are widely used antihistamines, which act by physically  
25 blocking the H<sub>1</sub> receptors and stopping histamine from reaching its target. Therefore, they could  
26 help to reduce the troublesome symptoms associated with allergy.<sup>2</sup> However, the improper use of  
27 these antihistamines may cause severe sedative effects including low blood pressure and  
28 decompensation.<sup>3</sup> The intravenous use of promethazine can cause tissue necrosis and it is not  
29 recommended. Several cases of overdose with diphenhydramine have also been reported; its effects  
30 include seizures and Brugada syndrome, in both cases due to the blockade of type Ia sodium  
31 channels.<sup>4</sup> To ensure their safe use and for the study of their metabolism and pharmacokinetics, it is  
32 necessary to establish simple and efficient approaches for the determination of the antihistamine  
33 drugs in biological samples.

34 To date, many methods have been developed for the determination of antihistamines in biological  
35 samples such as gas chromatography,<sup>5</sup> liquid chromatography<sup>6-11</sup> and capillary electrophoresis  
36 (CE).<sup>2,13,14</sup> Among these techniques, CE is the simplest and it requires much smaller amount of both  
37 samples and organic solvents. However, unfortunately, due to the small inner diameter of the  
38 capillary and the small sample injection amount, the detection sensitivity of CE sometimes is not  
39 good enough for trace analysis especially for biological samples when the common UV detection  
40 was used. To overcome this disadvantage, the most facile way to improve the sensitivity of CE is  
41 on-line preconcentration.

42 Micelle to solvent stacking (MSS), which was first introduced by Quirino in 2009,<sup>12</sup> is a novel

1  
2  
3  
4 43 on-line preconcentration technique for CE. The analyte focusing was based on the reversal of the  
5  
6  
7 44 direction of the effective electrophoretic mobility of the analytes at micelle to solvent stacking  
8  
9  
10 45 boundary (MSSB) formed between the sample solution and background solution (BGS). MSS is not  
11  
12 46 only efficient, rapid and easy to operate, but also can be used in different separation modes  
13  
14  
15 47 including capillary zone electrophoresis (CZE), micellar electrokinetic chromatography and  
16  
17 48 non-aqueous capillary electrophoresis.<sup>13</sup> Moreover, it can be applied for the concentration of some  
18  
19  
20 49 analytes from complex matrix samples.<sup>14-18</sup>  
21

22  
23 50 In this study, a simple, efficient and sensitive method for the quantitative determination of the  
24  
25 51 antihistamines (chlorpheniramine, diphenhydramine and promethazine) in human plasma sample  
26  
27  
28 52 was developed via on-line concentration of the analytes by MSS in CZE.  
29

## 32 33 34 35 54 **Experimental**

### 36 37 38 39 55 **Apparatus**

40  
41  
42  
43 56 All CE experiments were performed on a Beckman P/ACE MDQ CE System (Fullerton, CA,  
44  
45 57 USA) equipped with an auto sampler and a diode array detector. An uncoated fused-silica capillary  
46  
47 58 (Yongnian Ruifeng Optical Fiber Factory, Hebei, China) of 50 cm (effective length, 41.5 cm) × 50  
48  
49 59 μm i.d. was used throughout the experiments. Data acquisition and instrument control were carried  
50  
51 60 out using Beckman P/ACE MDQ 32 Karat software. The separation was performed at 25 °C with a  
52  
53  
54 61 voltage of 20 kV being applied. Unless otherwise stated, the detection wavelength was set at 200  
55  
56 62 nm. The conductivities were measured using a Delta 326 conductivity meter (Mettler Toledo,  
57  
58  
59 63 Shanghai, China).

## 64 Reagents, chemicals and materials

65 Chlorpheniramine maleate, diphenhydramine hydrochloride, promethazine hydrochloride and  
66 palmatine chloride (Internal standard, IS) (all >99%) were purchased from Chinese National  
67 Institute for the Control of Pharmaceuticals and Biological Products (Beijing, China). Sodium  
68 dodecyl sulfate (SDS) was purchased from Sigma-Aldrich (St. Louis, MO, USA). Sodium  
69 dihydrogen phosphate ( $\text{NaH}_2\text{PO}_4$ ), sodium hydroxide (NaOH), hydrochloric acid (HCl), methanol  
70 (MeOH) and acetonitrile were the products of Kaitong Chemical Reagent Co., Ltd. (Tianjin, China).  
71 MeOH and acetonitrile were of HPLC grade and other reagents were of analytical grade. All the  
72 reagents were used without further purification. All the solvents were filtered through a 0.45  $\mu\text{m}$   
73 Micro Science membrane filter (Tianjin Automatic Science Instrument Co., Ltd. Tianjin, China).  
74 The water used throughout the work was double-distilled using SZ-93 automatic double-distiller  
75 (Shanghai Yarong Biochemistry Instrumental Factory, Shanghai, China). Blank human plasma was  
76 obtained from the Baoding Blood Donor Service (Baoding, China).

77 A mixture stock solution containing each of chlorpheniramine maleate, diphenhydramine  
78 hydrochloride, promethazine hydrochloride at 1.0  $\text{mg mL}^{-1}$  and a stock solution of palmatine  
79 chloride at 1.0  $\text{mg mL}^{-1}$  were prepared in acetonitrile and stored in refrigerator at 4  $^\circ\text{C}$ . The BGS  
80 was prepared fresh every day and sonicated for 10 min prior to use.

## 81 Preparation of samples

82 For spiked plasma sample, a 100  $\mu\text{L}$  aliquot of blank human plasma sample was mixed with 20  
83  $\mu\text{L}$  of an appropriate concentration of the mixture solution and 20  $\mu\text{L}$  of 20  $\mu\text{g mL}^{-1}$  IS solution in a  
84 1.5 mL centrifugal tube. Then, 160  $\mu\text{L}$  acetonitrile was added and the mixture was vortexed for 1

1  
2  
3  
4 85 min. After the sample was centrifuged at 10 000 rpm for 10 min, the acetonitrile phase was  
5  
6  
7 86 separated, and then 100  $\mu\text{L}$  of the supernatant was transferred to a 0.5 mL vial and evaporated to  
8  
9  
10 87 dryness under a nitrogen stream. The residue was reconstituted in 100  $\mu\text{L}$  of sample matrix (10 mM  
11  
12 88  $\text{NaH}_2\text{PO}_4$  containing 10 mM SDS, pH 7.5) for CE analysis.  
13  
14  
15

16 89 For human plasma samples, a 100  $\mu\text{L}$  aliquot of human plasma sample was transferred to a 1.5  
17  
18  
19 90 mL centrifugal tube, to which 20  $\mu\text{L}$  of 20  $\mu\text{g mL}^{-1}$  IS solution and 180  $\mu\text{L}$  acetonitrile was added.  
20  
21  
22 91 Then, the sample was handled in the same way as described above for the spiked plasma sample.  
23  
24

## 25 92 **General electrophoresis procedure**

26  
27  
28

29 93 Prior to first use, the new capillary was flushed at 20 psi with MeOH for 20 min,  $\text{H}_2\text{O}$  for 10 min,  
30  
31  
32 94 1.0 M NaOH for 20 min,  $\text{H}_2\text{O}$  for 10 min and finally with BGS for 10 min. At the beginning of each  
33  
34  
35 95 working day, the capillary was conditioned at 20 psi with 0.1 M HCl for 5 min,  $\text{H}_2\text{O}$  for 5 min and  
36  
37  
38 96 then with BGS for 5 min. Between consecutive runs, the capillary was flushed with 1.0 M HCl for 5  
39  
40  
41 97 min, then with  $\text{H}_2\text{O}$  for 3 min and finally with the BGS for 3 min.  
42

43 98 For MSS, the analytes were prepared in sample matrix (10 mM  $\text{NaH}_2\text{PO}_4$  containing 10 mM SDS  
44  
45  
46 99 at pH 7.5). The BGS was 30 mM  $\text{NaH}_2\text{PO}_4$  (pH 7.5) containing 55% MeOH (v/v). The  
47  
48  
49 100 conductivities of the solutions were measured and the ratio of the conductivity between the BGS  
50  
51  
52 101 and sample matrix was 1.2 : 1. The sample solution was introduced into the capillary by  
53  
54  
55 102 hydrodynamic injection at 0.5 psi for 60 s. The ratios of the corrected peak areas (peak  
56  
57  
58 103 area/migration time) between the analytes and the IS were used as quantification signals.  
59

## 59 104 **Results and discussion**

60

### Effect of the pH of BGS

The electroosmotic flow (EOF) is proportional to the  $\zeta$  (zeta) potential of the capillary wall. It has been known that the EOF increases with the increase of the BGS pH due to the increase in the  $\zeta$  potential in CZE.<sup>19</sup> Therefore, pH will influence the migration time and separation efficiency of the analytes. In this study, the effect of the pH of BGS was evaluated in the range between 7.0 and 9.0. As a result, a complete separation of all the compounds was achieved at pH 7.5. Therefore, the pH at 7.5 for the BGS was chosen.

### Effect of organic solvent content

The concentration of MeOH in BGS is critical for MSS process. A sufficient MeOH in BGS will decrease the affinity between micelles and analytes, and then cause the reversal of effective electrophoretic mobility of the analytes in MSS. Otherwise, MSS will not occur. In this study, the 30 mM NaH<sub>2</sub>PO<sub>4</sub> buffers containing 40%, 45%, 50%, 55% or 60% (v/v) of MeOH, respectively, were tested to evaluate the influence of the organic solvent content on the separation. As a result, the maximum peak height was found when the concentration of MeOH was 55% in the BGS. In the experiments, the BGS containing different concentrations of acetonitrile was also investigated and the results indicated that the analytes could not be separated completely in such cases. Therefore, 55% MeOH was adopted.

### Effect of the concentration of NaH<sub>2</sub>PO<sub>4</sub> in BGS

The effect of the concentration of NaH<sub>2</sub>PO<sub>4</sub> in BGS was investigated by changing its concentration in the range from 10 to 50 mM (pH 7.5) while the MeOH concentration was kept

1  
2  
3  
4 125 constant at 55%. Consequently, as the concentration of  $\text{NaH}_2\text{PO}_4$  was increased from 10 to 30 mM,  
5  
6  
7 126 the resolution for all the analytes was improved. However, when the concentration of  $\text{NaH}_2\text{PO}_4$  was  
8  
9  
10 127 further increased to 40 mM or 50 mM, the peaks for the analytes became broadening with peak  
11  
12 128 heights being decreased slightly. Based on the above results, 30 mM  $\text{NaH}_2\text{PO}_4$  in BGS was  
13  
14  
15 129 selected.

### 17 130 **Effect of the concentration of SDS in sample matrix**

19  
20 131 For MSS to occur, the concentration of SDS should be higher than its critical micelle  
21  
22  
23 132 concentration to form micelles. However, the concentration should not be too high. Otherwise, the  
24  
25  
26 133 affinity between analytes and micelles would be too strong to reverse the effective electrophoretic  
27  
28 134 mobility of the analytes at MSSB, which should result in the failure of the MSS. To explore the  
29  
30  
31 135 effect of the SDS concentration in sample matrix on the resolution and focusing efficiency of the  
32  
33  
34 136 analytes, different concentrations of SDS (2.0 - 20 mM) were prepared in 10 mM  $\text{NaH}_2\text{PO}_4$  (pH 7.5)  
35  
36 137 and used as the sample matrix for evaluation. As a result, both the peak heights and peak areas for  
37  
38  
39 138 all the three analytes were increased with increased concentration of SDS from 2.0 to 10 mM. And  
40  
41  
42 139 then, when the concentration of SDS was changed from 10 to 20 mM, the peak height and peak area  
43  
44 140 for promethazine decreased slightly while the peak heights and peak areas for the other two analytes  
45  
46  
47 141 remained almost unchanged. Based on the above results, 10 mM SDS was chosen for further  
48  
49  
50 142 studies.

### 52 143 **Injection of sample solution**

54  
55 144 The effect of sample injection was studied by hydrodynamic injection at 0.5 psi with varying  
56  
57  
58 145 injection times (15, 30, 45, 60 and 75 s). The BGS consisted of 30 mM  $\text{NaH}_2\text{PO}_4$  (pH 7.5)  
59  
60 146 containing 55% MeOH. The sample matrix was 10 mM  $\text{NaH}_2\text{PO}_4$  containing 10 mM SDS. When

1  
2  
3  
4 147 the injection time was increased from 15 s to 60 s, the peak heights for the analytes were increased;  
5  
6  
7 148 however, when the sample was injected at 0.5 psi for 75 s, the peaks became broader and the  
8  
9  
10 149 separation between chlorpheniramine and promethazine became incomplete. Therefore, the  
11  
12 150 injection of sample at 0.5 psi for 60 s was selected.  
13

### 14 151 **Method validation**

16  
17 152 In order to validate the applicability of the developed method for the determination of the  
18  
19  
20 153 antihistamines in plasma samples, the features of this method in terms of linear range, repeatability  
21  
22  
23 154 and limits of detection (LODs) were evaluated. Calibration curves for antihistamines were  
24  
25  
26 155 investigated over the concentration range of 0.6-60  $\mu\text{g mL}^{-1}$  in human plasma samples with the  
27  
28 156 analyte concentration points at 0.6, 1.2, 3.0, 6.0, 12.0, 30.0 and 60.0  $\mu\text{g mL}^{-1}$  using 4.0  $\mu\text{g mL}^{-1}$   
29  
30  
31 157 palmatine as the IS. For each concentration level, five replicate determinations were performed  
32  
33  
34 158 under the optimum experimental conditions. The ratios of corrected peak area (peak area/migration  
35  
36 159 time) of the analytes to that of the IS were used as quantification signals. As a result, within the  
37  
38  
39 160 concentration range investigated, a good linearity existed for all the analytes with the correlation  
40  
41  
42 161 coefficients ( $r$ ) between 0.9971 and 0.9996. The LODs were calculated as the concentrations  
43  
44 162 corresponding to the signal three times of the baseline noise and the LODs of the antihistamines in  
45  
46  
47 163 human plasma samples were estimated to be in the range of 0.1-0.2  $\mu\text{g mL}^{-1}$ .  
48

49  
50 164 The precisions of the developed method were evaluated in terms of intra-day and inter-day  
51  
52 165 variations by the analysis of the spiked samples at the concentration of 0.6  $\mu\text{g mL}^{-1}$  in human  
53  
54  
55 166 plasma sample in the same day and on the five consecutive days, respectively. As shown in Table 1,  
56  
57  
58 167 the intra- and inter-day RSDs were lower than 7.5% and 9.1%, respectively, indicating a good  
59  
60 168 precision of the method.

1  
2  
3  
4 169 The focusing efficiency of the method was assessed by the comparison of its performance with  
5  
6  
7 170 that of normal CZE, as illustrated in Fig. 1. The mixture solution containing three antihistamines at  
8  
9  
10 171 150.0  $\mu\text{g mL}^{-1}$  and IS at 40.0  $\mu\text{g mL}^{-1}$  was prepared in BGS. Then, it was injected into the capillary  
11  
12 172 at 0.5 psi for 3 s in normal CZE. For the current method, mixture solution containing each of the  
13  
14  
15 173 analytes at 2.0  $\mu\text{g mL}^{-1}$  and the IS at 4.0  $\mu\text{g mL}^{-1}$  prepared in sample matrix was determined under  
16  
17  
18 174 the optimum conditions. The sensitivity enhancement factors (SEFs) in terms of peak height were  
19  
20 175 calculated according to the following equation:<sup>20</sup>

$$\text{SEF} = \frac{\text{quantification signal in the current method}}{\text{quantification signal in normal CZE}} \times \text{dilution ratio} \quad (1)$$

21  
22  
23 176  
24  
25  
26  
27 177 According to the above equation (1), compared with the conventional CZE injection procedure,  
28  
29  
30 178 the SEFs in terms of peak height were 63, 43 and 111 for diphenhydramine, chlorpheniramine and  
31  
32 179 promethazine, respectively.

33  
34  
35 180 The recoveries of the method were evaluated by analyzing the spiked human plasma samples at  
36  
37  
38 181 2.0, 7.5 and 15.0  $\mu\text{g mL}^{-1}$  each of the three antihistamines and at 4.0  $\mu\text{g mL}^{-1}$  of the IS. Fig. 2 shows  
39  
40 182 the electropherograms obtained by MSS-CZE for both the blank human plasma sample and the  
41  
42  
43 183 spiked human plasma sample with each antihistamine at 2.0  $\mu\text{g mL}^{-1}$ . The results showed that no  
44  
45  
46 184 significant interferences from the matrix were observed for the quantification of the analytes. As  
47  
48  
49 185 listed in Table 2, the recoveries of the method for diphenhydramine, chlorpheniramine and  
50  
51 186 promethazine in human plasma samples were 92.5-107.2%, 89.7-102.7% and 100.7-108.0%,  
52  
53  
54 187 respectively. The precisions expressed as RSDs ( $n = 5$ ) for the determination of the three  
55  
56 188 antihistamines were less than 7.6%.

### 58 59 189 **Comparison of the current method with other techniques**

60  
190 To evaluate the performance of the current method, a comparison of the current method with

1  
2  
3  
4 191 other reported relevant methods in respect of linearity, LODs and RSDs was made. As listed in  
5  
6  
7 192 Table 3, in comparison with the reported methods used for the determination of antihistamines, the  
8  
9  
10 193 sensitivity of the present method was comparable or even better than LC<sup>6,10</sup> and CE<sup>21</sup> methods, but  
11  
12 194 was inferior to GC-MS<sup>5</sup> and LC-MS<sup>10</sup> methods. However, more expensive MS detectors were  
13  
14  
15 195 required in those cases.

## 17 196 **Conclusions**

19  
20 197 In this work, a simple new method has been developed for the analysis of three antihistamines  
21  
22  
23 198 by using the novel CE on-line preconcentration technique MSS in CZE mode. The results  
24  
25  
26 199 demonstrated that the current method has high enrichment factor, good precision and sufficient  
27  
28 200 sensitivity with a short analysis time for the analysis of the antihistamines in human plasma sample.  
29

## 243 **Figure Captions**

244 **Fig. 1.** Comparison of the electropherograms obtained by normal CZE (A) and MSS-CZE (B). (A)  
245 Normal CZE: sample was  $150 \mu\text{g mL}^{-1}$  each of the analytes and  $40 \mu\text{g mL}^{-1}$  IS prepared in BGS;  
246 injection at 0.5 psi for 3 s. (B) MSS-CZE: sample was  $2.0 \mu\text{g mL}^{-1}$  each of the antihistamines and  
247  $4.0 \mu\text{g mL}^{-1}$  IS. Detection: 200 nm; Voltage: 20.0 kV; Peak identification: 1 – palmatine (IS), 2 –  
248 diphenhydramine, 3 – chlorpheniramine, 4 – promethazine, U – unknown.

249 **Fig. 2.** Electropherograms of blank human plasma (A) and human plasma spiked at  $2.0 \mu\text{g mL}^{-1}$   
250 each of the antihistamines and  $4.0 \mu\text{g mL}^{-1}$  IS (B). The insert was the zoomed electropherogram of  
251 the main part of the electropherogram B. Peak identifications are the same as those in Fig. 1.  
252

254 **Table 1**

255 The performance characteristics of the method

	Diphenhydramine	Chlorpheniramine	Promethazine
Range ( $\mu\text{g mL}^{-1}$ )	0.6-60.0	0.6-60.0	0.6-60.0
<i>r</i>	0.9996	0.9996	0.9971
LOD ( $\mu\text{g mL}^{-1}$ )	0.1	0.2	0.2
Intra-day RSD <sup>a</sup> ( <i>n</i> = 8) (%)	6.8	7.1	7.5
Inter-day RSD <sup>a</sup> ( <i>n</i> = 5) (%)	8.2	8.1	9.1
SEF	63	43	111

256 <sup>a</sup>The concentration of three antihistamines were 0.6  $\mu\text{g mL}^{-1}$ .
