Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about *Accepted Manuscripts* in the **Information for Authors**.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard <u>Terms & Conditions</u> and the <u>Ethical guidelines</u> still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

A novel organic-inorganic hybrid monocapped/bicapped Keggin structure $[Co^{II}(bpy)_3]_6(H_2bpy)[(Co^{II}bpy)_2(PMo_8^{VI-}Mo_4^{V}O_{40})]_3 [(Co^{II}bpy)(PMo_8^{VI}Mo_4^{V}O_{40})] \cdot 16H_2O$ (bpy = 2,2'bipyridine) was synthesized and shown to be an efficient visible light-driven catalyst for water oxidation.

The rising global energy demand and increasing adverse environmental impacts of fossil fuel consumption represent a daunting societal challenge.¹ To address this challenge, scientists have strived to develop clean and renewable energy resources, among which solar energy is a promising candidate.² The development of a scalable technology to efficiently convert solar energy to chemical fuels (e.g., photocatalytic splitting of water to hydrogen and oxygen) will meet the future energy need without environmental consequences. As a result, water oxidation, a critical step in converting sunlight to chemical energies, has received increasing attention in the past few decades.³ Significant efforts have recently been devoted to the discovery of water oxidation catalysts (WOCs) based on earth abundant elements in order to enable economical and scalable production of solar fuels.^{4,5} The design of molecular WOCs presents a significant challenge due to the highly oxidative nature of the active WOC and the reaction environment. Among organic ligands examined, 2,2'-bipyridine (bpy) is the most established ligand for synthesizing molecular WOCs owing to their oxidative stability.⁶ On the other hand, polyoxometalates (POMs), a subset of metal-oxo clusters with oxygen-enriched surfaces,⁷ have also been investigated as oxidatively stable ligands for designing active WOCs in the past few years.^{3i,8} The tetranuclear Co-based POM [Co₄(H₂O)₂(PW₉O₃₄)₂]¹⁰⁻ was, for example, demonstrated as an efficient homogeneous catalyst in visible-light-driven water oxidation using $[Ru(bpy)_3]^{2+}$ as photosensitizer and $Na_2S_2O_8$ as sacrificial electron acceptor.^{9,10,11} A number of other Co- and Ni-based POM WOCs have recently been used for visible-light-driven water oxidation reactions.^{8b,8d,10,12} As Keggin-type POMs are the most stable structures in POM chemistry,¹³ we aimed at designing Co-based POMs of Keggin-type structures for water oxidation. Herein we wish to report the synthesis and characterization of a novel organic-inorganic hybrid $\label{eq:construction} \begin{array}{ll} \hline monocapped/bicapped & Keggin structure & [Co^{II}(bpy)_3]_6(H_2bpy)_1 \\ [(Co^{II}bpy)_2(PMo_8^{VI}Mo_4^{V}O_{40})]_3[(Co^{II}bpy)(PMo_8^{VI}Mo_4^{V}O_{40})] \cdot 16H_2O, \end{array}$ 1, and its use as an efficient visible light-driven catalyst for water oxidation. In this strategy, we combine the well-established bpy ligand with stable Keggin-type POMs to design robust organic-inorganic hybrid molecular WOCs.

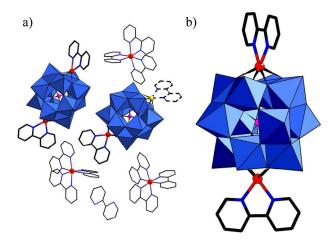

Fig. 1 a) The asymmetric unit of 1 contains one $(Co^{II}bpy)_2(PMo_8^{VI}Mo_4^VO_{40})]^3$ unit and one $[(Co^{II}bpy)_{1.5}(PMo_8^{VI}Mo_4^VO_{40})]^4$ unit along with three $Co^{II}(bpy)_3$ and one Hbpy cations. b) The bicapped Keggin structure showing coordination of the $Co^{II}bpy$ unit to four terminal oxygen atoms of the POM. All of the hydrogen atoms and lattice water molecules have been omitted for clarity. Colour code: blue polyhedra: Mo; red ball: Co; yellow ball: disordered Co; violet: P; black: C; blue: N. The disordered Co^{II}(bpy) subunit is shown with dotted lines.

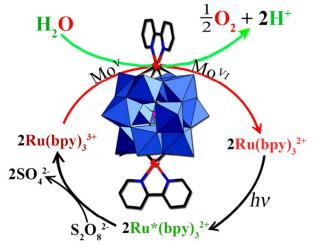

1 was synthesized hydrothermally by heating a mixture of Na₂MoO₄, Co(Ac)₂, 2,2'-bpy, 4,4'-bis(phosphonomethyl)biphenyl, Na₂HPO₄, and a small amount of 85% H₃PO₄ in water. Single-crystal X-ray diffraction studies revealed that **1** crystallizes in the monoclinic space group $P2_1/c$ (Table **S1**, ESI). Each asymmetric unit of **1** consists of two crystallographically distinct POM anions: one $[(Co^{II}bpy)_2(PMo_8^{VI}Mo_4^{VO}O_{40})]^4$ (Fig. 1). The latter unit results from an average of a 50:50 occupancy disorder of one bicapped Keggin $([(Co^{II}bpy)_2(PMo_8^{VI}Mo_4^{VO}O_{40})]^{3-})$ and one monocapped

Journal Name

Page 2 of 5

 $[(Co^{II}bpy)(PMo_8^{VI}Mo_4^{V}O_{40})]^{5-}$. The 0.5 $(Co^{II}bpy)$ units in the latter POM anion resides on the inversion center, which crystallographically relates the bicapped and monocapped Keggin structures and introduces the occupancy disorder. There are thus three bicapped Keggin structures and one monocapped Keggin structure in the formula unit of 1. In 1, the charge is balanced by six $[Co^{II}(bpy)_3]^{2+}$ and one protonated bpy as counter cations in the asymmetric unit.

Bond valence sum (BVS, Table **S2** in ESI) calculations¹⁴ gave an average valence of 5.67 for all 24 Mo atoms, corresponding to the expected valence 5.66 of $Mo_{16}^{V}M_{32}^{U}$. On the other hand, BVS calculations confirmed that all cobalt atoms are in +2 oxidation state. The assignments of oxidation states are confirmed by X-ray photoelectron spectroscopy (XPS) measurements (**Fig. S1**, ESI). Four deconvoluted peaks were observed in the Mo 3d region at 231.39, 232.51, 234.30, 235.55 eV, attributed to Mo^V 3d_{5/2}, Mo^{VI} 3d_{3/2}, Mo^{VI} 3d_{3/2} respectively.¹⁵ The binding energy values of Co atoms in **1** at the 2p region are 780.90, 786.85, 796.80 and 803.00 eV, corresponding to Co^{II} 2P_{3/2}, Co^{II} 2P_{1/2} and their respective satellite peaks.¹⁶ Thermal gravimetric analysis (TGA) indicates a weight loss of 2.35% in the range of 25-350 °C, attributing to the removal of about 16 crystal water molecules (**Fig. S2**, ESI). The experimental PXRD pattern of **1** is in good agreement with the simulated PXRD one from the single-crystal X-ray diffraction, demonstrating the phase purity of **1** (**Fig. S3**, ESI).

Scheme 1. Compound 1 catalyzes water oxidation to generate O_2 under the visible light irradiation, using $[Ru(bpy)_3]^{2+}$ as photosensitizer and $S_2O_8^{2-}$ as sacrificial electron acceptor.

The process of photocatalytic water oxidation under visible light illumination is shown in Scheme 1. A series of photocatalytic water oxidation experiments of compound 1 were carried out using a 80 mM borate buffer solution (initial pH=9.0) with $[Ru(bpy)_3]Cl_2$ as photosensitizer and Na₂S₂O₈ as sacrificial electron acceptor. Photocatalytic water oxidation reactions were carried out at different concentrations of catalyst 1 (0-10 µM, Fig. 2a) in 20 mL solutions.¹⁷ O₂ forms rapidly after irradiation and the amount of O₂ generation is quantified by online GC analyses. The total amount of generated O2 increased as the catalyst concentration increases, whereas the O₂ evolution rate decreased sharply over time. The O₂ yields (O₂ yield = $2 \times \text{mole of } O_2/\text{ mole of } Na_2S_2O_8$) increased from 5% to 17% with an increase in concentration of 1. A maximum O₂ yield of 17% corresponded to the generation of 8.4 µmol O₂ when the concentration of 1 was 10 µM. Meanwhile, the turnover number (TON, defined as mole of O₂ / mole of catalyst) slightly decreased from 51.2 to 42.2 with the catalyst concentration increasing from 2.5 to 10 µM. An initial turnover frequency (TOF, defined as mole of O_2 / mole of catalyst / Δt) in the first 300 s remains stable between 0.08 to 0.10 s⁻¹ with 10 μ M of **1**, indicating a 1st order kinetic dependence on the catalyst concentration. The relative low O_2 yield indicates that non- O_2 -evolving persulfate consumption reactions compete with the O_2 evolution process competes, which have been extensively studied earlier.¹⁸ The competing non- O_2 -evolving persulfate consumption that O_2 total yield increases as the concentration of catalyst increases (**Fig. 2a**), since the desired O_2 evolution reaction is enhanced as the concentration of **1** increases. Without **1**, a maximum amount of only 0.12 μ mol O_2 could be detected in 60 minutes under the same experimental condition, substantiating the catalytic role of **1** in the water oxidation process.

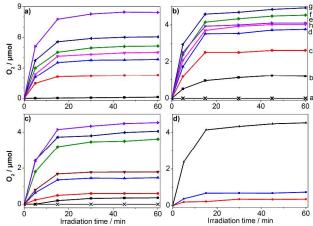

Fig. 2 Photochemical O₂ production from borate buffer solution (80 mM, pH = 9.0). **a)** 1.0 mM [Ru(bpy)₃]Cl₂, 5.0 mM Na₂S₂O₈, and various concentrations of **1** (from bottom to top): 0, 2.5, 3.75, 5, 6.25, 7.5, and 10 μ M. **b)** 5 μ M **1**, 1.0 mM [Ru(bpy)₃]Cl₂, and various concentrations of Na₂S₂O₈: a, 0.0; b, 1.0; c, 2.0; d, 3.0; e, 4.0; f, 5.0; g, 6.0; h, 7.0 mM; **c)** 5 μ M **1**, 5.0 mM Na₂S₂O₈, and various concentrations of [Ru(bpy)₃]Cl₂ (from bottom to top): 0.0, 0.1, 0.2, 0.4, 0.5, 0.8, 0.9, and 1.0 mM. **d)** 1.0 mM [Ru(bpy)₃]Cl₂, 5.0 mM Na₂S₂O₈, and 1.76 μ M mixture of Co(bpy)₃²⁺, Co(bpy)₂²⁺ and Co(bpy)²⁺ (red), 1.6 μ M Co(NO₃)₂ (blue), or 5 μ M **1** (black). Other conditions: 300W Xe lamp, 420-800 nm; total reaction volume 20 mL; vigorous stirring (1.5 × 10³ rpm).

The dependences of the O_2 generation rate on the concentrations of sacrificial electron acceptor Na₂S₂O₈ and photosensitizer [Ru(bpy)₃]Cl₂ were also examined systematically as shown in Fig. **2b** and **c**. With an increase in the concentration of $Na_2S_2O_8$ from 1 to 6 mM, the total amount of O₂ evolution increased from 1.2 to 4.9 µmol, resulting in an increase in TON from 12.0 to 49.2. When the concentration of Na₂S₂O₈ further increased to 7 mM, however, only 4.1 μ mol O₂ could be detected. Such an O₂ generation dependence on $Na_2S_2O_8$ concentration was also observed in other POM systems. $^{8b,\ 8d,\ 18a}$ The O_2 yield decreased from 13% to 6% as the concentration of Na₂S₂O₈ increased from 1 to 7 mM. When the concentration of photosensitizer [Ru(bpy)₃]Cl₂ was below 1.0 mM, there was a positive correlation between the amount of evolved O₂ and the photosensitizer concentration. When the concentration of [Ru(bpy)₃]Cl₂ was varied from 0.1 to 1.0 mM, the O₂ yield increased from 0.7% to 9.1% and the TON increased from 3.52 to 45.32. No O_2 was detected in the absence of $Na_2S_2O_8$ or $[Ru(bpy)_3]Cl_2$. It should also be noted that there are six $[Co(bpy)_3]^{2+}$ ions in each formula unit of 1. The potential catalytic activity of $[Co(bpy)_3]^{2+}$ was investigated by replacing the 1 with $[Co(bpy)_3](ClO_4)_2$ (Fig. S4). O₂ evolution was detected with a maximum amount of 0.22 µmol after 60 minutes of irradiation, corresponding to only 4.8% of the amount of O₂ generated in the

Journal Name

presence of **1**. This result indicates that $[Co(bpy)_3]^{2+}$ ions in **1** are not responsible for the observed water oxidation activity.

Under all of the tested conditions, the O₂ evolution saturates in about 15 min, consistent with the results seen for other POM-based WOCs.^{8d,18a} This phenomenon was explained by the complete consumption of $Na_2S_2O_8$ in this time period (due to non-O₂-evolving) persulfate consumption processes).^{18a} Nevertheless, when we added another 5 mM $Na_2S_2O_8$ (the same amount as the first round) to the system (5 μ M 1) after the catalysis, no more O₂ was generated upon irradiation. Similarly, no more O2 generation was observed when we added either [Ru(bpy)₃]Cl₂ (1 mM, the same amount as the first round) alone or [Ru(bpy)₃]Cl₂ and Na₂S₂O₈ at the same time after the first round of catalysis. The O₂ generation did not recover even after the addition of fresh POM catalyst into the system after the first round. In addition, after simultaneously adding all three components ($[Ru(bpy)_3]Cl_2$, Na₂S₂O₈, and fresh 1) to the illuminated mixture after the first round of photocatalytic water oxidation and adjusting pH to 9.0, still no oxygen could be detected after illumination for another hour. These results indicate that the catalyst is poisoned quickly during the first catalytic run. We also noticed that, after completion of the first round (with 5 μ M 1, irradiated 60 min), the pH of the buffer solution decreased from 8.92 to 8.52. To test the pH influence on the catalysis, we performed another photocatalytic experiment at pH 8.5 in borate buffer. The total amount of O₂ evolution was 1.5 µmol (33% of the pH 9.0 buffer at the same condition, Fig. S5, ESI). The decrease in pH is an important contributor to the loss of O₂ evolution activity after the first round.

 Co^{2+} and CoO_x (form in situ from Co^{2+}) in aqueous solution are both known to be active WOCs.^{5a, 19} The molecular WOCs also have the possibility to decompose into catalytically active Co^{2+} or CoO_x . In the case of 1, however, we have several experimental evidences to rule out either Co^{2+} or CoO_x as the active catalyst in our system. Firstly, we performed extraction of the POM after photocatalysis.^{11b} The irradiated solution (80 mM pH 9.0 borate buffer containing 5 uM 1, 1.0 mM [Ru(bpy)₃]Cl₂, and 5.0 mM Na₂S₂O₈, irradiated for 1h) was treated by adding an excess amount of tetrabutylammonium bromide to extract the POM out of the aqueous solution. Then, the amount of Co-containing species remaining in the aqueous solution was quantified by the inductively coupled plasma-mass spectrometry (ICP-MS). Only 1.6 µM Co and 7.8 µM Mo were detected in the aqueous solution, indicating less than 3.3% of 1 had decomposed. Moreover, the FT-IR spectrum of 1 extracted from the post-reaction solution shares the same pattern with the pristine sample of 1 (Fig. S6, Table S3). Furthermore, Dynamic Light Scattering (DLS) experiments were performed on the reaction mixture before and after photocatalysis for 1. A particle size of about 1.6 nm was determined for the solution of 1 both before and after the photocatalysis, corresponding to the size of the POM anion (Fig. S7 a&b). To ensure the decomposed Co^{2+} or $[Co(bpy)]^{2+}/[Co(bpy)_2]^{2+}$ is not the dominant WOC species, we determined WOC using 1.6 µM Co(NO₃)₂ or 1.76 µM $[Co(bpy)]^{2+}/[Co(bpy)_2]^{2+}/[Co(bpy)_3]^{2+}$ mixture²⁰ (the same amount as simple cobalt ions decomposed from 5 μ M 1). Only ~0.73 μ mol O₂ was observed from 1.6µM Co(NO₃)₂ and ~0.35 µmol O₂ from 1.76 μ M [Co(bpy)]²⁺/[Co(bpy)₂]²⁺/[Co(bpy)₃]²⁺ mixture, which accounts for 16.1% and 7.7% O₂ yield of 1, respectively (Fig. 2d). We also conducted a control experiment with a higher concentration of the $[Co(bpy)]^{2+}/[Co(bpy)_2]^{2+}/[Co(bpy)_3]^{2+}$ mixture (contains 35) μ M [Co(bpy)]²⁺ and [Co(bpy)₂]²⁺, the same amount of Co as that in 5 μ M 1). The O₂ yield of the mixture is still lower than that of 1 (Fig. **S8**). In contrast to **1**, formations of large nanoparticles of 60 nm/100 nm were observed by DLS in both control experiments with $Co(NO_3)_2$ and the $[Co(bpy)]^{2+}/[Co(bpy)_2]^{2+}/[Co(bpy)_3]^{2+}$ mixture,

indicating the formation of CoO_x in these cases (**Fig. S7** d&e). With these experimental results, we conclude that the active WOC in **1** is unlikely to be free cobalt ion or $[Co(bpy)]^{2+}/[Co(bpy)_2]^{2+}$ species formed from decomposition of **1**.

The photocatalytic activity of 1 after aging for 5h was also compared to that of the fresh catalyst (**Fig. S9**, ESI). The amount of O_2 evolution did not change after the catalyst solution of 1 was left to stand for 5h. We can infer that 1 is stable for at least 5h under the catalytic conditions. The UV-Vis measurement of 1 also support this conclusion: the absorption spectrum of the solution did not change after standing for 5 hours (**Fig. S10**, ESI). We also performed cyclic voltammetry (CV) on 1 (**Fig. S11**, ESI) which showed large, irreversible oxidative waves that correspond to catalytic water oxidation with an onset potential of ~0.98 V (*vs.* Ag/AgCl). From the results, we can conclude that oxidation of cobalt(II) in compound 1 to cobalt(III) species by $[Ru(bpy)_3]^{3+}$ is thermodynamically feasible.

In conclusion, we have synthesized a novel bicapped/monocapped Keggin-type POM (1) via a hydrothermal reaction and demonstrated the viability of 1 as a molecular water oxidation catalyst under photocatalytic conditions. The present WOC is built from Keggin-type POM and bpy, two of the most robust building blocks for designing molecular WOCs. The photocatalytic water oxidation activity of 1 has been studied systemically. A TON of up to 49 was observed, before the catalyst was poisoned by species generated during the catalytic process. The stability of 1 under photocatalytic conditions was demonstrated by DLS, extraction experiment, and UV-Vis and FT-IR spectra. This work also demonstrates that POM clusters have the ability to enhance the WOC activity of bipyridine-substituted cobalt complexes and thus suggests new opportunities in designing hybrid molecular WOCs using POM and metal-bpy building blocks.

We thank the National Thousand Talents Program of P.R. China, and the 985 Program of Chemistry and Chemical Engineering disciplines of Xiamen University and the US National Science Foundation (DMR-1308229) for funding support and Ms. Ruiyun Huang for administrative help.

- 17 Each formula of **1** contains three bicapped Keggin structures and one monocapped Keggin structure. The catalytic activity based on the Co^{ll}bpy unit is likely 7 times lower than the value that is calculated based on the formula of **1**.
- 18 (a) S. Tanaka, M. Annaka, and K. Sakai, *Chem. Commun.*, 2012, 48, 1653–1655; (b) K. Henbest, P. Douglas, M. S. Garley, and A. Mills, *J. Photochem. Photobiol. A.*, 1994, 80, 299–305; (c) A. B. Tossi and H. Görner, *J. Photochem. Photobiol. B*, 1993, 17, 115–125.

- 20 The [Co(bpy)₃]²⁺: [Co(bpy)₂]²⁺: [Co(bpy)]²⁺ (1:9:1, 1.76 μM total Co concentration) mixture contains 1.6μM [Co(bpy)]²⁺ and [Co(bpy)₂]²⁺. [Co(bpy)₃]²⁺ is known to be an inactive WOC. See ESI for more details.
