Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

Graphical abstract

Dynamic kinetic resolution driven, asymmetric transfer hydrogenation reactions of cyclic sulfamidate imine-5-carboxylate esters were developed. Applications of the new methodology to stereoselective syntheses of the Taxotere side-chain and (-)-*epi*-Cytosaxone are described.

Dynamic kinetic resolution driven, asymmetric transfer hydrogenation reactions of cyclic sulfamidate imine-5-carboxylate esters were developed. Applications of the new methodology to stereoselective syntheses of the Taxotere side-chain and (-)-*epi*-Cytosaxzone are described.

1,2-Amino alcohol motifs, including those found in β -amino- α -hydroxy acids, are present in a vast range of natural products and pharmaceutically related compounds.¹ In addition, the relative and absolute stereochemistry of the 1,2-amino alcohol moiety generally governs the biological activities of these substances. Therefore, the development of methods for stereoselective synthesis of members of this family has received considerable attention.^{1a,2}

Transition metal catalyzed-asymmetric transfer hydrogenation reactions (ATH)³ of carbonyl compounds containing configurationally labile stereogenic C-H centers, accompanied by dynamic kinetic resolution (DKR), have become an efficient and powerful technique for controlling the stereochemistry at two contiguous stereogenic centers. Examples of processes of this type include ATH of α -substituted- β -ketoesters,⁴ β -ketoamides,⁵ α -alkoxy- β -keto phosphonates,⁶ 1,2-diketones,⁷ α -ketoesters,⁸ and α -ketophosphonates.⁹ However, only a few reports exist describing ATH reactions of imines that are accompanied by DKR.¹⁰ In this context, we recently described a highly efficient procedure for ATH-DKR of prochiral cyclic sulfamidate imines, using HCO₂H/Et₃N as the hydrogen source and chiral Rh-catalysts (Scheme 1).^{10a-b} In this early effort, we showed that ATH of 4,5-disubstituted cyclic sulfamidate imines **2**, possessing configurationally labile stereogenic centers (C5), is accompanied by DKR. It was also observed that DKR is caused by rapid racemization at the acidic stereogenic C₅ position adjacent to the imine carbon under the reaction conditions. In fact, introduction of an aryl in place of a methyl group at C-5 of **2** leads to drastic improvement in the stereoselectivity of the ATH reaction (*eg.*, from 75% ee for **3** to 98% ee for **5**), an obvious consequence of the enhanced acidity of the H-5 (Scheme 1).^{10a}

While considering other strategies to improve the stereoselectivity of ATH-DKR reactions of cyclic imine **2**, we envisioned that introduction of carboxylate group at C-5 would also enhance the acidity of H-5 and, as a result, would promote

high levels of stereoselectivity in the ATH-DKR reaction.

- Chiral transition metal-catalysts **1a-1e**

Scheme 1

Below, we describe the results of an investigation exploring this proposal, which led to the first examples of highly efficient ATH reactions of cyclic imines **6**, which are accompanied by DKR and can be applied in the synthesis of stereochemically enriched, chiral cyclic sulfamidate-5-carboxylate esters **7**.

The racemic cyclic imine-5-carboxylate esters **6**, used in this work, were prepared from α -hydroxy- β -keto ester (**B**) and sulfamoyl chloride by using a modification of a previously described procedure (Scheme 2).¹¹

Scheme 2. Synthesis of 4-substituted sulfamidate imine-5-carboxylates **6**

Racemic 4-phenyl-5-methoxycarbonyl cyclic imine **6a** was selected as the model substrate in initial efforts aimed at the identification of the most suitable catalyst systems for the ATH reactions. Reactions of **6a** were performed using the known chiral transition metal catalysts **1a-e** (0.5 mol%) and employing

HCO₂H/Et₃N as the hydrogen source in EtOAc at rt (Table 1).

As the results given in Table 1 show, the efficiencies and stereochemical outcomes of ATH reactions of **6a** are strongly affected by both the nature of the transition metal and the diamine ligands. For example, reaction of this substrate using Ru-catalysts with diamine ligands bearing electron rich or electron deficient arylsulfonyl groups (**1c**,^{3c} **1d**,¹² **1e**^{4a}) proceed to very low conversions (Table 1, entries 3-5). However, ATH of **6a** using Ir-catalyst **1b**¹³ reaches completion in 0.5 h (conversion >99%) but takes place with a low level enantioselectivity (30% ee). Finally, the results reveal that ATH-DKR of **6a** with Rh-catalyst (*R,R*)-**1a**,¹⁴ which possesses TsDPEN and pentamethylcyclopentadienyl ligands, for 0.5 h at rt produces (*S,S*)-**7a** in the highest conversion (>99%) and level of stereoselectivity (>25:1 dr, 98% ee).

The influence of solvent on the ATH reaction of **6a** catalyzed by (*R,R*)-**1a** was investigated. In most of the solvents tested (EtOAc, CH₂Cl₂, Cl(CH₂)₂Cl, CHCl₃, toluene, DMF, MeOH, THF, and 2-propanol), ATH of **6a** takes place completely to form (*S,S*)-**7a** with high levels of stereoselectivity (>25:1 dr, 84-99% ee) (see, Table S2 in SI-1). For the purpose of experimental convenience and based on optimization of stereoselectivity, further ATH reactions were carried out in EtOAc as solvent.

The scope and limitations of the ATH-DKR reaction were explored using a variety of cyclic sulfamidate imine-5-carboxylates (**6**). All reactions were carried out in EtOAc (25 °C) under the optimized reaction conditions employing (*R,R*)-**1a** (0.5 mol%) as the catalyst and a 5:2 mixture of HCO₂H/Et₃N as the hydrogen source. The results are summarized in Table 2.

ATH of **6a** with (*R,R*)-**1a** under the optimized reaction conditions produces a mixture of stereoisomeric 4,5-*cis* sulfamidates, in which the (4*S*,5*S*)-**7a** isomer predominates (98% ee, 92% yield, Table 2, entry 1). None of the 4,5-*trans* sulfamidates are detected in the crude product mixture by using ¹H-NMR spectroscopic analysis. These results show that hydrogen addition to **6a** occurs exclusively from the less hindered face of the cyclic imine moiety.^{10a} In addition, ATH-DKR reactions of 4-phenyl-cyclic imine-5-carboxylates containing different ester moieties, such as isopropyl (**6b**) and benzyl (**6c**), also produce the corresponding cyclic sulfamidates (**7b**, **7c**) with excellent efficiencies and

^aReaction conditions: **6** (0.5 mmol), (*R,R*)-**1a** (0.5 mol%), HCO₂H/Et₃N (5:2, 0.5 mL), EtOAc (5 mL), rt. ^bDetermined by ¹H NMR analysis of the crude product mixtures (isolated yields in parentheses). ^cDetermined by using chiral HPLC. Only 4,5-*cis* products were detected by using ¹H NMR analysis of crude product mixtures. ^dAbsolute configuration of **7b-i**, **7k-q** was determined by analogy to **7a** and **7j**. ^eSee, Scheme S1 in Supplementary Information-1. ^f(*S,S*)-**1a** (0.5 mol%) was used. ^g1:1 mixture of HCO₂H/Et₃N was used as hydrogen source. ^hDetermined by using X-ray crystallographic analysis (CCDC 1007235). ⁱ0.1 mol% of (*R,R*)-**1a** (S/C = 1,000) was used. ^jee of ring-opened derivatives derived from **7r** and **7t** respectively (see, Scheme S2 in SI-1). ^kNot determined.

ATH reaction of **6a** under the optimized conditions, except in this case using the (*S,S*)-**1a** as catalyst, produces the antipodal sulfamidate (*R,R*)-**7a** with an efficiency and stereoselectivity (98% ee, 94% yield) that match those accompanying reaction using (*R,R*)-**1a** (Table 2, entry 5). ATH-DKR of cyclic sulfamidate imines possessing either electron-withdrawing or -donating groups at the *meta*- or *para*-positions on the phenyl ring leads to production of the corresponding sulfamidates in high yields and stereoselectivities. However, ATH of the cyclic imine **6e** possessing an *ortho*-methyl substituted phenyl group is sluggish, reaching only 20% conversion even after 12 h. Based on the results of recent studies which show that the HCO₂H/Et₃N (F/T) ratio has a significant effect on both the ATH rate and level of enantioselectivity,^{5b, 6,15} we employed the 1:1 instead of a 5:2 mixture of F/T as the hydrogen source for ATH of **6e**. This reaction proceeds to completion in 12 h and is attended by a slightly decreased level of stereoselectivity (92% ee) (Table 2, entries 6 and 7). Cyclic imines containing heteroaromatic moieties also serve as suitable substrates for the ATH-DKR reaction, as exemplified by the results of reactions of furan **6p** and thiophene **6q** (Table 2, entries 19 and 20). Importantly, we also found that the catalyst loading can be reduced to 0.1 mol% (S/C = 1,000) in the ATH-DKR reaction of **6j** without deterioration of optical purity when the process is carried out using a longer reaction time (Table 2, entry 13). ATH reaction of 4-alkyl substituted cyclic sulfamidate imine-5-carboxylates was also explored. The results show that the efficiencies and stereoselectivities of the processes are sensitive to the steric bulkiness of the 4-alkyl group. Thus, ATH-DKR reaction of 4-(*n*-propyl) cyclic imine **6r** is complete in 1.5 h (91% ee) but that of the 4-phenethyl containing cyclic imine **6s** requires 12 h for completion and occurs with a lower level of stereoselectivity (76% ee) (Table 2, entries 21 and 22). ATH-DKR reaction of 4-cyclohexyl-substituted cyclic imine **6t** is more sluggish resulting in only 50% conversion after 24 h. However, by employing 1:1 mixture of HCO₂H/Et₃N as the hydrogen source, reaction of **6t** reaches completion in 48 h but it takes place with a lower level of stereoselectivity (47% ee) (Table 2, entries 23 and 24).

The cyclic sulfamidates **7** produced in these reactions are valuable intermediates for the synthesis of various chiral β-amino-α-hydroxy carboxylic acids or 1,2-functionalized amines¹⁶ such as those present in the side chain of the anticancer drug Taxotere (**10**)¹⁷ and the potent cytokine modulator (-)-*epi*-cytoxazone (**12**)^{2b,18} (Figure 1).

Figure 1

In order to demonstrate the utility of the methodology developed in this effort, we employed it in the synthesis of the Taxotere side-chain **10**¹⁷ (Scheme 3).

Scheme 3 Reaction conditions: (a) (Boc)₂O, Et₃N, cat. DMAP, CH₂Cl₂, 100%; (b) i. PhCO₂NH₄, DMF, 55 °C, 12 h; ii. 1N HCl, CH₂Cl₂, 6 h, rt, 82%; (c) KCN, MeOH, 65 °C, 85%; (d) 1N NaOH, MeOH-THF, rt, 88%.

Accordingly, (*S,S*)-**7a** formed by ATH-DKR reaction of **6a** is converted to its *N*-Boc derivative, which upon treatment with PhCO₂NH₄ undergoes ring opening^{10a,19} to form (*2R,3S*)-**8a**. Selective removal of the *O*-benzoyl group in **8a** using KCN¹¹ in MeOH and subsequent hydrolysis of methyl ester **9a** produces the Taxotere side-chain **10**¹⁷ (ca. 61% overall yield over 4 steps from (*S,S*)-**7a**).

Scheme 4 Reaction conditions: (a) (Boc)₂O, Et₃N, cat. DMAP, CH₂Cl₂, 94%; (b) i. PhCO₂NH₄, DMF, 55 °C, 12 h; ii. 1N HCl, CH₂Cl₂, 6 h, rt, 100%; (c) KCN, MeOH, 65 °C, 86%; (d) NaBH₄, MeOH, rt, 92%; (e) NaH, THF, rt, 95%.

An additional example demonstrating the usefulness of the methodology is found in the synthesis of (-)-*epi*-cytoxazone (**12**) starting with (*S,S*)-**7j** (Scheme 4).^{2b,18} (ca. 70% overall yield over 5 steps from (*S,S*)-**7j**).

In summary, a convenient and highly stereoselective method for the preparation of 4-substituted cyclic sulfamidate-5-carboxylate esters **7** was developed in this investigation. The process, involving asymmetric transfer hydrogenation accompanied by dynamic kinetic resolution (ATH-DKR), uses HCO₂H/Et₃N as the hydrogen source and chiral Rh catalysts (*S,S*)- or (*R,R*)-Cp*RhCl(TsDPEN). Most of the ATH-DKR reactions probed in this study undergo rapid (30 min) and highly stereoselective under mild and experimentally convenient conditions (rt, without the need for solvent degassing or an inert atmosphere). The utility of this methodology was demonstrated by its application to syntheses of the Taxotere side-chain and (-)-*epi*-cytoxazone. This research was financially supported by grants from the National Research Foundation of Korea (2008-2004732) and Korea Research Institute of Chemical Technology (SI-1405).
