This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
1D, 2D and 3D coordination polymers of 1,3-phenylene diisonicotinate with Cu(I)/Cu(II): Cu_2I_2 building block, anion influence and guest inclusions

Gargi Mukherjee, and Kumar Biradha*

The reactions of a flexible bidentate ligand 1,3-phenylene diisonicotinate (L) with Cu(I/II) salts afforded coordination polymers with varied dimensionalities and guest inclusion capabilities. Complexation of L with CuI resulted in a 2D-network with (4,4) topology and inclusion of guest molecules such as CHCl_3, bromobenzene, nitrobenzene and benzonitrile. The treatment of L with Cu(PF_6)_2 and Cu(ClO_4)_2 resulted in one-dimensional network containing M_2I_2 macrocycles and a 4-fold interpenetrated three dimensional network having quartz topology respectively. The 1D-networks included CHCl_3 as guests and interpenetrated 3D-network includes tetrahedral water clusters.

Coordination polymers are being studied extensively due to their intriguing structures and applicative aspects such as gas sorption, separation, catalysis, gels and photoluminescence. The synthesis of new ligands and exploration of their coordination abilities to form coordination polymers had developed as an active area of research during the past decade as there is a direct correlation between structures and properties. A large amount of CPs reported to date corresponds to bis(pyridyl) or bis carboxylate ligands. Although, the coordinating groups, pyridine and carboxylate, play a major role in the formation of CPs, the backbone that connects these functional groups play a more significant role in tailoring the network topologies and geometries and nature of the cavities of the CPs. We have recently initiated studies on CPs of bis(pyridyl) ligands containing secondary amides and phenyl or alkyl groups -(CH_2)_n- as backbone. These studies revealed that CPs containing ligands with shorter spacers such as -(CH_2)_2- or -(CH_2)_4- exhibit versatility in producing 1D chains containing cavities, open 2D-networks, chiral 2D-networks and interpenetrated 2D-networks (both parallel and perpendicular mode). On the other hand, the ligands with phenyl, hexyl or octyl spacers have consistently formed 2D-networks which are further linked by amide-to-amide hydrogen bonds.

Fromm group and others have explored the network geometries of ethanediyli bis(isonicotinate) with Cu(I) halides and AgNO_3. It was observed that diverse types of 1D-chains were afforded depending on the use of solvents. Further, M(II) halide (Zn, Hg, Co) complexes of the same ligand were also reported to yield iso-structural metallamacrocycles with inclusion of guest molecules. Furthermore, the role of spacers containing ester groups which anchor bis-pyridyl moieties in tailoring the network geometries and properties were demonstrated by Hosseini group. A set of ester-pyridine ligands containing various spacers (hexaethylene glycol, 1,1'-spirobi(indane), dibromo fluorine, isomannide, (R)-6,6'-dibromo-1,1'-binaphthyl) were synthesized and their combination with different metal salts produced a variety of novel networks including double stranded interwound linear networks, double stranded interwoven, triple stranded and quadruple-stranded helices. In this paper, we wish to present our studies on CPs of angular bis-pyridyl ligand (L) containing m-phenylene and ester functionalities as backbone. We note here that the corresponding amide based derivative of L was explored to form CPs and CP based gels, to the best of our knowledge to date no CPs of L are explored. Generally, angular or V-shaped ligands are known to form helical coordination networks with transition metal ions. Studies on CPs derived from N,N'-bis-(4-pyridincarboxamidate),1,3-benzene and its reverse analogue N,N'-bis-(4-pyridyl)isophthalamidate with transition metal salts (e.g., Cu(II) and Zn(II)) revealed to yield mainly 1D networks.

The ligand 1,3-phenylene diisonicotinate (L) was synthesized by reacting resorcinol with isonicotinic acid in chloroform in the presence of dicyclohexylcarbodiimide (DCC). The Cu(I) and Cu(II) metal salts were considered for complexation with L, as we have shown earlier that related amide containing ligands have more propensity to form crystalline complexes with these salts. The diffusion of a CH_3CN solution of CuI into a MeOH solution containing ligand L and liquid aromatic guest resulted in bright orange coloured crystals of complexes {{Cu_2L_2}(L_2)(2 guest)}_{1-4}, containing CHCl_3 (1), nitrobenzene (2), benzonitrile (3) and bromobenzene (4), respectively, as guests. The single crystal X-
ray diffraction analyses revealed that all contain 2D-networks, and 1 crystallized in P2(1)/c while 2-4 crystallized in P2(1)/n space group (Figure 1). The asymmetric unit of all contain one unit of each Cu(I), iodide, ligand L, and guest molecule. The Cu(I) and F form CuI₂ SBU in which each Cu(I) adopts a tetrahedral geometry as two L and two F are coordinated to it. The isonicotinoyl planes of ligand L are nearly perpendicular to its central Cu₂-ring in all the four complexes (74.96, 83.74; 67.55, 83.66; 70.55, 82.62; 66.69, 86.20). However the position of C=O groups differ, they point in opposite direction in 1 while they are on the same side in 2-4 (Figure 2a).

Interestingly, the Cu-Cu distance in Cu₂I₂ SBU was found to be much shorter (2.634 Å) in 1 than the other three (2.854, 2.776 & 2.822 Å) complexes. Nevertheless, in all the structures, the Cu₂I₂ SBU acts as four connected planar node with four units of L are linked to it and results a 2D network of (4,4) topology containing rhomboidal cavities of dimension 12.6x32.8 Å. The layers found to be highly corrugated such that there exist continuous channels within the layers. In other words, the 2D-layer can also be described as the joining of 1D-helices which run along b-axis (Figure 1e). These helices contain elliptical channels that are occupied by a column of guest molecules (Figure 1d). Chloroform molecules were not located in 1; however, aromatic guest molecules in 2, 3 and 4 were located and found to form a dimeric column along b-axis via C–H–O (2.799, 3.283 Å), C–H–N (3.566 Å), and C–H–Br (3.838, 3.974 Å), respectively (Figure 1f). In 1, the Cu(I) SBU’s are joined by the ligand with a distance of 16.716 Å.

The layers pack via the interdigitation of adjacent helices which occurs through aromatic interactions between the pyridyl moieties and the central phenyl rings (4.299, 4.180 Å) and O=C=O interactions (Figure 2). Although the geometry of ligand is different in 1 and 2-4, the interior environment of the channel remains similar given the interdigitation of the layers. The solvent accessible volume amount to 31.7%, 29.7%, 31.8% and 31.5% respectively in 1-4. We note here that previously the amide analogue of 1 which contains -HN-C₂H₂-NH- in place of -O-C₂H₉-O- of 1 was shown by us to form similar type of 2D-layers with CuI₂ SBU. These layers found to include only CHCl₃/CHBr₃ molecules as a guest across the layers but not within the layer as was shown here.

The reactions of L with Cu(I) metal salts such as Cu(PF₆)₂ and Cu(ClO₄)₂ are also investigated to study the network geometries of the resultant materials, guest inclusion properties, anion interaction and also to understand the difference between SBU based and non SBU based complexes. The reaction of L with Cu(PF₆)₂ and Cu(ClO₄)₂ resulted in the crystals of complexes [{Cu(L)(H₂O)₂}2(PF₆)₃(CHCl₃)],₅, and [{Cu₂(L)₃(H₂O)₃}ClO₄]₆, respectively, in MeOH-H₂O-CHCl₃ solvent system.

The crystal structure analysis of 5 reveals that it crystallized in monoclinic C2/c space group and the asymmetric unit is constituted by one unit of each Cu(I), L, PF₆ ion, half chloroform and coordinated water molecules (Figure 3). The Cu(I) centres adopt octahedral environment with four ligand units at equatorial sites and two water molecules at axial sites. The geometry of the ligand is somewhat similar to the one observed in the complex 1, however it resulted in the formation of 1D-network containing M₂L₂ macrocycles which facilitated given the angular nature of the ligand. The CHCl₃ molecule is situated at the centre of M₂L₂ macrocycles. The 1D-networks are linked to 2D-network via O–H–O hydrogen bonds between coordinated H₂O and O=C of ester group (Figure 3b). We note here, similar type of hydrogen bonding was also observed in the CPs of amide analogues. The layers packed on each other via C–H–O and edge-to-face (3.56 Å) aromatic interactions. It is found that these cavities in 1D-chain are suitable only for CHCl₃, unlike 1-4, as the reactions with other guest molecules failed to produce crystalline materials.

Complex 6 crystallizes in C₂ space group (Figure 4) and the asymmetric unit is constituted by two Cu(II) ions with occupancies of 1 and 0.5, three units of L, anions and water molecules. The Cu(II) centres exhibit two coordination modes: square pyramidal (Cu1) and distorted octahedral geometry (Cu2). The Cu1 and coordinated H₂O (Cu-O 2.267(10) Å) lies on the glide plane and connected to four units of L in equatorial positions (Cu-N: 1.984(7), 2.032(7) Å). Whereas, the Cu2 exhibits distorted octahedral geometry with two water molecules at axial sites, one of which exhibits very weak interaction (2.649 Å) and removed during final refinement, due to very high thermal motion, using PLATON squeeze option. The three ligands almost have similar conformational geometries with overall length (N-atom to N-atom) of 13 Å. Although the metal centre has square planar coordination with respect to pyridyl groups, the angular nature of the ligand results in tetrahedral building block. The depiction of Cu(II) centres as nodes and ligands as node-connections reveals that the network has quartz-type topology and the voids of each network are filled by 4-fold interpenetration of such networks. Despite of 4-fold interpenetration, the structure contains three types of channels: two channels were filled by water tetramers and the third one is filled by anions which hydrogen bond to coordinated water. It is interesting to mention here that the water tetramers found to exhibit distorted tetrahedron geometries with O–O distances ranging from 2.2 to 3.2 Å.

The UV-vis absorption spectra of the free ligand (L) and complexes 1-3 in solid state were recorded at room temperature. L shows peaks at 267 and 300 nm (Figure 5a). Complex 1 shows broad absorption in the range 250-550 nm with three intense peaks at 268, 352 and 520 nm. Similar type of absorption behaviour was also observed for the complexes 2 (256, 350, 507 nm) and 3 (263, 350, 510 nm) with a blue shift in all three peaks compared to 1. The blue shift of absorption edges can be correlated with the longer Cu–Cu distances in SBUs of 2 (2.854 Å) and 3 (2.776 Å) compared to 1 (2.634 Å). Further solid state luminescence study, at the excitation wavelength of 325 nm, was carried out on complexes 1-3 at room temperature (Figure 5b) to notice if there are any apparent differences in their emission properties. An emission (reddish yellow) peak of complex 1 was observed at 637 nm. As for complex 2, it is blue shifted to 633 nm, and becomes sharper compared to 1, while complex 3 exhibits emission band at 634 nm which is broader compared to 1. The luminescent emission of these complexes can be attributed to strong cuprophlic interactions observed in the complexes. At room temperature all three complexes show a low-energy (LE)
broad emission centred around 630 nm. Based on the previous reports on the Cu(I) clusters, the LE emissions are assigned to iodide-to-copper charge transfer transition (XMCT, X=halogen).\textsuperscript{15}

In conclusion, exo-bidentate bis-pyridyl ligand L was shown to form coordination networks of versatile topologies with Cu(I) salts. The networks observed here includes 1D chain with cavity occupied by anion and CHCl\textsubscript{3} guest molecules, two-dimensional (4,4) network with elliptical channels which are occupied by variety of guest molecules, and three-dimensional 4-fold interpenetrated network with quartz topology which accommodates water tetramers. The angular nature of the ligand imparted some helicity in to the two-dimensional and three-dimensional networks.
