This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
A New Strategy to Achieve La$_2$O$_2$CN$_2$:Eu$^{3+}$ Novel Luminescent One-dimensional Nanostructures

Xiaomin Guo, Jinxian Wang, Xiangting Dong*, Wensheng Yu and Guixia Liu

**Introduction**

Recently, inorganic rare earth (RE) compounds containing several kinds of anions have been paid much attention as optical materials. Different kinds of anions can make their structure, physical and chemical properties unique and multiple. The structure of (REO)X$_n$ is composed of alternating layers of the (REOX)$_{2n+}$ complex cations and X$^{n-}$ (X=S, Cl, Br, CO$_3$, SO$_4$, CN$_2$) anions$^9$. The (REOX)$_{2n+}$ structural unit is very stable, which is assumed to be the reason for the exceptional luminescence properties of the RE oxycyanides$^{25}$. The exceptional luminescence and structural properties of the RE oxycyanides give an excellent opportunity to study the changes in the optical properties of a given RE$^{3+}$ ion when the structure of the host is changed$^{26,27}$. Europium ions doped luminescent materials as the main and outstanding red emitting phosphors have attracted much attention of the scientists, and the $^7F_0→^5D_J$ (J=0-4) transitions of Eu$^{3+}$ ions result in important applications in displays$^{8,9}$, optical telecommunications$^{18,19}$, and laser devices$^{11,12}$. More recently, their unique advantages have been envisaged in biosensing and medical diagnosis$^{15,18}$. Lanthanum oxycyanamide (La$_2$O$_2$CN$_2$) is the new luminescent matrix, which has potential applications in the fields of electroluminescent devices, polarizers and laser host materials. The luminescence properties of Ln$_2$O$_2$CN$_2$:RE$^{3+}$ (Ln=La, Y and Gd; RE=Pr and Eu) have been reported$^{13,14}$. All the homologous Ln$_2$O$_2$CN$_2$:RE$^{3+}$ compounds were synthesized following the solid-state metathesis (SSM) method, and the morphologies of the products are only bulk particles. Presently, no reports on the preparation of La$_2$O$_2$CN$_2$:Eu$^{3+}$ nanofibers and nanoribbons are found in the literatures.

Nanofiber and nanobelt are new kinds of one-dimensional nanostructures with special morphologies. They have attracted increasing interest of scientists owing to their anisotropy, large length-to-diameter ratio and width-to-thickness ratio, unique optical, electrical and magnetic performances$^{19-28}$. Research on the fabrication and properties of nanofibers and nanobelts has become one of the popular subjects of study in the realm of nanomaterials. Electrospinning is one technique that allows fabrication of continuous fibers with diameters ranging from tens of nanometers up to micrometers$^{29}$. It has been found that the electrospinning technology have already been applied in the fields of ultrafiltration, tissue engineering, catalysis, as well as devices that include solar cells, transistors, sensors, memories, etc$^{29-36}$. In this paper, Eu$^{3+}$ doped La$_2$O$_2$CN$_2$ nanofibers and nanoribbons were successfully prepared by calcinating the electrospun PVP/[(La(NO$_3$)$_3$+Eu(NO$_3$)$_3$] composites followed by cyanamidation, and the structure, morphology and PL properties of the resulting samples were investigated in detail. In addition, the formation mechanisms of La$_2$O$_2$CN$_2$:Eu$^{3+}$ nanofibers and nanobelts are also proposed. More importantly, the new strategy and construct technique are of universal significance to fabricate other rare earth oxycyanamide nanostructures with various morphologies.

1 Experimental Sections

2.1 Chemicals

Polyvinyl pyrrolidone (Mw=90000, AR) were purchased from Tianjin Bodi Chemical Co. Ltd. N,N-dimethylformamide (DMF, AR) was bought from Tiantai Chemical Co. Ltd. La$_2$O$_3$ (99.99%) and Eu$_2$O$_3$ (99.99%) were supplied by China Pharmaceutical Group Shanghai Chemical Reagent Company. Nitric acid (HNO$_3$, AR) was bought from Beijing chemical Co. Ltd. All chemicals were directly used as received without further purification.

2.2 Fabrication of La$_2$O$_2$CN$_2$:x%Eu$^{3+}$ nanofibers

La$_2$O$_2$CN$_2$:x%Eu$^{3+}$ [x=1, 3, 5, and 7, x stands for molar...
percentage of Eu\(^{3+}\) to (Eu\(^{3+}\)+La\(^{3+}\)) nanofibers were prepared by calculating the electrospray. PVP/[La(NO\(_3\)]\(_3\)+Eu(NO\(_3\)]\(_3\)] composites by cyanamidation. In the typical procedure of preparing representative La\(_2\)O\(_2\)CN\(_2\):3%Eu\(^{3+}\) nanofibers, 0.9716 g of La\(_2\)O\(_3\) and 0.0325 g of Eu\(_2\)O\(_3\) were dissolved in dilute HNO\(_3\) (1:1, volume ratio) at elevated temperature to form RE(NO\(_3\)]\(_3\)+6H\(_2\)O powders (RE=La\(^3+\), Eu\(^{3+}\)) by evaporating the excess HNO\(_3\) and water from the solution by heating. The RE(NO\(_3\)]\(_3\)+6H\(_2\)O powders were dissolved in 15.8 g of DMF. Then 2.2 g of PVP was added into the above solution under stirring for 4 h to form homogeneous transparent spinning solution. In the spinning solution, the mass ratio of PVP, rare earth nitrate and DMF is 11:10:79. Subsequently, the above spinning solution was loaded into a hypodermic syringe with a stainless steel needle tip of the syringe while the cathode was connected to the anode of the DC high power supply was connected to the Fe net collector plate. The positive voltage applied to the tip was 13 kV and the solidification distance was 18 cm. The ambient temperature was 18-25 °C, and the relative humidity was 40%-60%. The flow rate of the spinning solution was determined by the contents of PVP in solutions because PVP can adjust the viscosity of solutions. PVP/[La(NO\(_3\)]\(_3\)+Eu(NO\(_3\)]\(_3\)] composite nanofibers were obtained on the collector with the evaporation of DMF. Then the above composite nanofibers were calcined at a rate of 1 °C/min and remained for 8 h at 700 °C. Then, La\(_2\)O\(_2\)CN\(_2\):3%Eu\(^{3+}\) nanofibers were obtained. The La\(_2\)O\(_2\)CN\(_2\):3%Eu\(^{3+}\) nanofibers were loaded into a graphite boat-shaped crucible and calcination temperature was decreased to 200 °C with a rate of 1 °C/min and remained for 12 h under a flow of gaseous ammonia. Then, the calcination temperature was increased to 950 °C at the heating rate of 1 °C/min and the solidification distance was 15 cm, and the other preparation conditions were the same as those of the La\(_2\)O\(_2\)CN\(_2\):3%Eu\(^{3+}\) nanofibers. Other series of La\(_2\)O\(_2\)CN\(_2\):x%Eu\(^{3+}\) (x=1, 5 and 7) nanofibers were prepared by the similar procedures except for different doping molar concentrations of Eu\(^{3+}\) ions.

2.3 Synthesis of La\(_2\)O\(_2\)CN\(_2\):3%Eu\(^{3+}\) nanobelts

RE(NO\(_3\)]\(_3\)+6H\(_2\)O (RE = La\(^3+\), Eu\(^{3+}\)) powders were prepared by dissolving 0.9716 g of La\(_2\)O\(_3\) and 0.0325 g of Eu\(_2\)O\(_3\) in dilute HNO\(_3\) (1:1, volume ratio) at elevated temperature. After evaporating, the obtained RE(NO\(_3\)]\(_3\)+6H\(_2\)O powders were dissolved in 14.0 g of DMF. Then 4.0 g of PVP was added into the above solution under stirring for 12 h to form homogenous transparent spinning solution. In this spinning solution, the mass ratio of PVP, rare earth nitrate and DMF is 20:10:70. The positive voltage applied to the tip was 8 kV and the solidification distance was 15 cm, and the other preparation conditions were the same as those of the nanofibers. Thus PVP/[La(NO\(_3\)]\(_3\)+Eu(NO\(_3\)]\(_3\)] composite nanobelts were obtained on the collector with the evaporation of DMF. Then the above composite nanobelts were calcined at a rate of 1 °C/min and remained for 8 h at 700 °C, and La\(_2\)O\(_2\)CN\(_2\):3%Eu\(^{3+}\) nanobelts were obtained. La\(_2\)O\(_2\)CN\(_2\):3%Eu\(^{3+}\) nanofibers were fabricated through cyanamidation of the obtained La\(_2\)O\(_2\)CN\(_2\):3%Eu\(^{3+}\) nanofibers using the same process, as described in section 2.2. The variant preparation conditions for preparing the La\(_2\)O\(_2\)CN\(_2\):3%Eu\(^{3+}\) nanofibers and nanobelts were listed in Table 1.

2.4 Characterization methods

X-ray diffraction (XRD) analysis was performed using a Rigaku D/max-RA XRD diffractometer with Cu Kα radiation of 0.15406 nm. The size and morphology of the products were investigated by an XL-30 field emission scanning electron microscope (SEM) made by FEI Company. The purity of the products was examined by OXFORD ISIS-300 energy dispersive X-ray spectrometer (EDX). The specific surface areas of the nanostructures were measured by a V-Sorb 2800P specific surface area and pore size analyzer made by Gold APP Instrument Corporation. The excitation and emission spectra of samples were recorded with a Hitachi F-7000 fluorescence spectrophotometer using a Xe lamp as the excitation source. In order to compare the PL intensity of the samples, all the determination conditions remain identical. All the measures were performed at room temperature.

3 Results and discussion

3.1 XRD analysis

Fig.1 shows the XRD patterns of the La\(_2\)O\(_2\)CN\(_2\):Eu\(^{3+}\) nanofibers with different molar concentration of Eu\(^{3+}\). As seen from Fig. 1, the characteristic diffraction peaks of all samples are observed in 20 range of 10°–90°, all of which can be readily indexed to those of the tetragonal crystal phase with primitive structure of La\(_2\)O\(_2\)CN\(_2\) (PDF No. 83-0304), and the space group is 14/mmm. No other impurity phase can be detected at the current doping concentrations, indicating that the Eu\(^{3+}\) ions are completely inserted into the La\(_2\)O\(_2\)CN\(_2\) host lattice through replacing the La\(^{3+}\) ions. However, the diffraction peaks of all samples are shifted to the higher diffraction angles compared with those of the La\(_2\)O\(_2\)CN\(_2\) (PDF No. 83-0304), as shown in the insets of Fig. 1, 2, due to the different ionic radii between La\(^{3+}\) and Eu\(^{3+}\), meaning that the lattice constants of La\(_2\)O\(_2\)CN\(_2\):Eu\(^{3+}\) nanostructures have been slightly changed. The lattice constants are calculated using the following expression:

\[
\sin^2 \theta = \left( \frac{\lambda}{2a} \right)^2 \left( h^2 + k^2 \right) + \left( \frac{\lambda}{2c} \right)^2 l^2
\]

where \(\lambda\) value is 1.5406 Å, \(a\), \(b\), and \(c\) are diffraction indexes, and the lattice constants of La\(_2\)O\(_2\)CN\(_2\):Eu\(^{3+}\) nanoparticle are \(a=b=4.07\) Å and \(c=12.21\) Å respectively. The same structures are obtained for the La\(_2\)O\(_2\)CN\(_2\):3%Eu\(^{3+}\) nanostructures and nanofibers, as manifested in Fig. 2.
nanofibers greatly decrease due to loss of the PVP and associated annealing and cyanamidation at 950°C, the diameters of the La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanobelts (d) of PVP/[La(NO$_3$)$_3$+Eu(NO$_3$)$_3$] composite nanobelts with the thickness from 120 nm to 230 nm, as revealed in Fig.3b. The SEM image from the Au film coated on the surface of the sample for SEM observation. No other elements are found in the samples, indicating that the La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanostructures are highly pure.

### 3.2 Morphology observation
The morphologies of the products are characterized by scanning electron microscope (SEM). Fig. 3 demonstrates the representative SEM images of the composite nanofibers, composite nanobelts, La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanofibers and La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanobelts. From the SEM image of Fig. 3a, it can be noticed that the PVP/[La(NO$_3$)$_3$+Eu(NO$_3$)$_3$] composite nanofibers have smooth surface and uniform diameter. After annealing and cyanamidation at 950°C, the diameters of the nanofibers greatly decrease due to loss of the PVP and associated organic components, as-formed La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanofibers have relatively smooth surface and uniform diameter ranging from 120 nm to 230 nm, as revealed in Fig.3b. The SEM image of PVP/[La(NO$_3$)$_3$+Eu(NO$_3$)$_3$] composite nanobelts with the thickness of 230 nm (shown in the inset of Fig. 3c) is manifested in Fig. 3c, the composite nanobelts are smooth and uniform. Clearly, uniform La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanobelts with the thickness of 192 nm are synthesized and have relatively smooth surface, as indicated in Fig. 3d. Preliminarily, we can conclude that the cyanamidation process can retain the morphologies of the nanofibers and nanobelts used as precursors.

### 3.3 BET analysis
The specific surface areas of the La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanofibers and nanobelts are determined by BET method. The measured BET surface area adsorption isotherms of La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanostructures are shown in Fig.6. The adsorption saturation capacity of nanofibers and nanobelts, which are obtained

**Fig. 3** SEM images of PVP/[La(NO$_3$)$_3$+Eu(NO$_3$)$_3$] composite nanofibers (a), La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanofibers (b), PVP/[La(NO$_3$)$_3$+Eu(NO$_3$)$_3$] composite nanobelts (c) and La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanobelts (d)

**Fig. 4** Distribution histograms of the diameters of PVP/[La(NO$_3$)$_3$+Eu(NO$_3$)$_3$] composite nanofibers (a), La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanofibers (b) and the widths of PVP/[La(NO$_3$)$_3$+Eu(NO$_3$)$_3$] composite nanobelts (c) and La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanobelts (d)

**Fig. 5** EDX images of La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanofibers (a) and nanobelts (b)

---
respectively from the Fig. 6, are 3.45 mL, 3.15 mL, respectively. The BET model surface areas are calculated using the following formula:

$$\text{BET} = \left( \frac{V_m}{10^3} \right) \times 6.02 \times 10^{23} \times 1.62 \times 10^{-19}$$

where $V_m$ is the adsorption saturation capacity, and the BET model surface areas of nanofibers and nanobelts are calculated to be 15.0 m$^2$·g$^{-1}$ and 13.7 m$^2$·g$^{-1}$, respectively. Remarkably, the specific surface area of La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanofibers is bigger than that of La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanobelts.

**Fig. 6** BET surface area adsorption isotherms of La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanofibers (a) and nanobelts (b)

### 3.4 Photoluminescence properties

Fig. 7 illustrates the excitation (monitored by 622 nm) and emission (excited by 284 nm) spectra of the La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanofibers. The excitation spectrum (Fig. 7a) exhibits one broad band in the range from 250 to 350 nm. The predominant peak at 284 nm is associated with the charge-transfer band (CTB) of Eu$^{3+}$-O$_2$$^-$, the CTB of La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ corresponds to the electron transition from the 3p orbital of O$^-$ to the 4f orbital of Eu$^{3+}$. In the longer wavelength region, the characteristic f-f transition peaks (at 367 nm, $^7$F$_{0}$$\rightarrow$^7$D$_{0}$; 383nm, $^7$F$_{0}$$\rightarrow$^5$D$_{2}$; 395nm, $^7$F$_{0}$$\rightarrow$^5$D$_{4}$; 417nm, $^7$F$_{0}$$\rightarrow$^5$D$_{6}$; 468nm, $^7$F$_{0}$$\rightarrow$^5$D$_{8}$) of Eu$^{3+}$ ions can be observed with very weak intensity compared with that of the CTB.

The emission (excited by 284 nm) spectrum of La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanofibers is shown in the Fig. 7b. The luminescence from the $^5$D$_{0}$ level of the Eu$^{3+}$ ion is found to be efficient, whereas emission from the higher excited states $^5$D$_{1,2}$ is quenched due to the multi-phonon processes. The spectrum is characterized by an intense, characteristic red emission of predominant peaks which splits into two peaks at 614 nm and 622 nm originating from the transition along with dominating electric dipole transitions $^5$D$_{0}$$\rightarrow$^7$F$_{2}$, indicating that Eu$^{3+}$ occupies a site with no inversion center low symmetries in the La$_2$O$_2$CN$_2$:Eu$^{3+}$ nanofibers. The magnetic dipole transitions $^5$D$_{0}$$\rightarrow$^7$F$_{0}$, $^5$D$_{2}$$\rightarrow$^7$F$_{1}$, especially $^5$D$_{0}$$\rightarrow$^7$F$_{3}$ are weak. These transitions are hypersensitive to crystal-structure and chemical surroundings.

**Fig. 7** Excitation (a) and Emission (b) spectra of the La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanofibers

Fig. 8 demonstrates the PL spectra of La$_2$O$_2$CN$_2$:Eu$^{3+}$ nanofibers doped with various concentrations of Eu$^{3+}$ ions. The inset is the dependence of its PL intensity on the Eu$^{3+}$ content in the La$_2$O$_2$CN$_2$ matrix. PL decay curves of La$_2$O$_2$CN$_2$:Eu$^{3+}$ nanofibers with different doping concentrations of Eu$^{3+}$ ions, and the strongest excitation and emission spectra can be obtained when the doping molar concentration of Eu$^{3+}$ is 3%. Obviously, the luminescence intensity of La$_2$O$_2$CN$_2$:Eu$^{3+}$ nanofibers increases with the increase of the concentration of Eu$^{3+}$ from the beginning, reaches a maximum value with the Eu$^{3+}$ concentration of 3%, and then decreases with further increase in Eu$^{3+}$ concentration. While considering the mechanism of energy transfer in phosphors, the concentration quenching can be explained in more detail by critical distance (Rc), and the critical distance (Rc) between Eu$^{3+}$ ions for energy transfer can be calculated using the formula that was proposed by Blasse and Grabmaier as below:

$$R_c = 2 \times \left( \frac{3}{4\pi N} \right)^{\frac{1}{3}}$$

where $V$ is the volume of the unit cell, $X_c$ is the critical concentration of activator ions and $N$ is the number of formula unit per unit cell. In case of La$_2$O$_2$CN$_2$:3%Eu$^{3+}$ nanofibers, $X_c=0.03$, $V=0.2022$ nm$^3$ and $N=4$. Therefore, the average distances Rc between Eu$^{3+}$ ions for energy transfer is calculated to be $R_c=1.4766$ nm when the doping optimum molar concentration is 3%.

**Fig. 8** Excitation (a) and Emission (b) spectra of La$_2$O$_2$CN$_2$:Eu$^{3+}$ nanofibers doped with various concentrations of Eu$^{3+}$ ions. The inset shows the dependence of its PL intensity on the Eu$^{3+}$ content in the La$_2$O$_2$CN$_2$ matrix. PL decay curves of La$_2$O$_2$CN$_2$:Eu$^{3+}$ nanofibers with different doping concentrations of Eu$^{3+}$ ions. The insets are excited by 284 nm and monitored at 622 nm.
The results were observed in the references[22,23]. The results are that the nanofibers have more surface luminescence centers than the nanobelts, as a result, the nanofibers have stronger luminescence than the nanobelts. Similar results were observed in the references[22,23].

Fig. 9 Luminescence decay curves of La2O2CN2:3%Eu3+ nanofibers doped with various concentrations of Eu3+ ions

Fig. 10 Excitation (a) and Emission (b) spectra of La2O2CN2:3%Eu3+ nanofibers and nanobelts

Fig. 11 Luminescence decay curves of La2O2CN2:3%Eu3+ nanofibers and nanobelts. Fig. 10 demonstrates the comparison between the excitation and emission spectra of the La2O2CN2:3%Eu3+ nanofibers and nanobelts measured under the same conditions. It can be found that the nanofibers have higher PL intensity than that of nanobelts. From above BET analysis, it is found that the specific surface area of the La2O2CN2:3%Eu3+ nanofibers and nanobelts determined by BET method are 15.0 m²/g and 13.7 m²/g, respectively. Remarkably, the specific surface area of the nanofibers is bigger than that of the nanobelts, implying that the nanofibers have more surface luminescence centers than the nanobelts, as a result, the nanofibers have stronger luminescence than the nanobelts. Similar results were observed in the references[22,23].

Fig. 11 depicts the luminescence decay curves of La2O2CN2:3%Eu3+ with different morphologies excited by 284 nm and monitored at 622 nm. The curves also can be well-fitted into a double-exponential function and the fitted lifetime is τ=1.023 ms for the La2O2CN2:3%Eu3+ nanofibers higher than that (0.946 ms) for the La2O2CN2:3%Eu3+ nanobelts. The results reveal that the fluorescence lifetime is direct proportion to the luminescence intensity.

3.5 CIE analysis

In general, color can be represented by the Commission Internationale de L’Eclairage (CIE) 1931 chromaticity coordinates. Fig.12a shows the chromaticity coordinates of La2O2CN2:x%Eu3+ [x=1, 3, 5 and 7] nanofibers, and the chromaticity coordinates are respectively determined to be [(0.612, 0.354), (0.617, 0.355), (0.601, 0.349), (0.625, 0.352)]. The chromaticity coordinates of La2O2CN2:3%Eu3+ nanofibers (0.617, 0.355) and nanobelts (0.577, 0.359) are represented in Fig.12b. These results indicate that the color emissions can be tuned by changing the concentration of doping activator ions and the morphologies of nanostructures. These nanostructures could show merits of red emissions, which are considered to be promising candidates for application in LEDs.

According to the above analysis, we advance the formation mechanisms of La2O2CN2:Eu3+ nanostructures, as shown in Fig. 13. PVP, Eu(NO3)3 and La(NO3)3 were mixed with DMF to form spinning solution. PVP acted as template during the formation of La2O2CN2:Eu3+ nanostructures. La3+, Eu3+ and NO3- were mixed or absorbed onto PVP to form PVP[(La(NO3)3+Eu(NO3)3)] composite nanofibers and nanobelts via electrospinning. Because the viscosity of the spinning solution for fabricating nanofibers was lower, and the applied voltage was higher, the spinning velocity was faster. The charge repulsion force acted on the radial direction of the jets had not enough time to stretch the jets into belt shape, resulted in the formation of composite nanofibers. Whereas the viscosity of the spinning solution for preparing nanobelts was higher, and the applied voltage was lower, so that the spinning velocity was slower. The charge repulsion force had adequate time to stretch the jets into belt shape, led to the formation of composite nanobelts. The morphologies of the composite nanostructures were basically retained after performing the following calcination and cyanamidation process. During calcination process, PVP was decomposed soon and carbonized, as well as nitrates were decomposed and oxidized to produce NO2, and eventually evaporated from the composite fibers and belts. With the increase in the calcining temperature, La3+ and Eu3+ ions could combine with O2 coming from air, to form La2O3:Eu3+ crystallite, and many crystallites were combined into nanoparticles, and finally these nanoparticles were mutually connected to generate La2O3:Eu3+ nanofibers and nanobelts. Afterwards, the above products were cyanamidated in a graphite boat under the flowing NH3. In the cyanamidation process, the carbon from graphite boat reacts with the flowing ammonia gas to produce H2CN2 and H2, then the as-prepared La2O2:Eu3+ reacts with H2CN2 and graphite to produce La2O2CN2:Eu3+, CO and H2 in the high temperature. During the process, graphite boat is not only a container, but also a reactant substance through reacting with NH3 and La2O3:Eu3+ in composite nanofibers and nanobelts via electrospinning.
the heating process. Reaction schemes for formation of La$_2$O$_2$CN$_2$:Eu$^{3+}$ nanostructures proceed as follows:

$$\text{PVP}([\text{La(NO$_3$)$_3$}+\text{Eu(NO$_3$)$_3$}] + \text{O}_2 \xrightarrow{700^\circ C} \text{CO}_2 + \text{H}_2\text{O} + \text{NO}_2 + \text{La}_2\text{O}_3:Eu^{3+})$$

$$2\text{NH}_3 + \text{C} \rightarrow \text{H}_2\text{CN}_2 + 2\text{H}_2$$

$$\text{La}_2\text{O}_2\text{CN}_2:Eu^{3+} + \text{CO} + \text{H}_2$$

If the La$_2$O$_2$Eu$^{3+}$ nanofibers were cyanamidated in a traditional corundum boat-shaped crucible loaded with some carbon rods (S2) under the flowing NH$_3$ in the same heating process, La$_2$O$_2$CN$_2$:Eu$^{3+}$ cannot be obtained except La$_2$O$_3$:Eu$^{3+}$, which is confirmed by XRD patterns of the product, as indicated in Fig. 14. On the other hand, if La$_2$O$_2$:Eu$^{3+}$ nanofibers or nanobelts directly mix with the liquid H$_2$CN$_2$, the H$_2$CN$_2$ and H$_2$CN$_2$ nanofibers or nanobelts into pieces when heating. Cyanamidation technology we proposed here is actually a solid-gas reaction, which has been proved to be an important method, not only can retain the morphology of precursor, but also can fabricate pure phase La$_2$O$_2$CN$_2$:Eu$^{3+}$ nanostructures.

4 Conclusions

In summary, pure tetragonal phase La$_2$O$_2$CN$_2$:Eu$^{3+}$ nanofibers and nanobelts with space group of I4/mmm have been successfully prepared. The as-prepared La$_2$O$_2$CN$_2$:Eu$^{3+}$ nanostructures have relatively smooth surface, the diameter of the nanofibers is 173.6±1.67 μm, and the width of the nanobelts is 622 nm originated from the energy levels transition $^7$F$_{0} \rightarrow ^{5}D_{0}$ of Eu$^{3+}$, indicating that Eu$^{3+}$ occupies a site without inversion symmetry in the La$_2$O$_2$CN$_2$:Eu$^{3+}$ nanostructures. The strongest luminescence of La$_2$O$_2$CN$_2$:x%Eu$^{3+}$ nanofibers is obtained when doping concentration of Eu$^{3+}$ is 3%. The nanofibers have the stronger photoluminescence than the nanobelts under the same measuring conditions. Color-tuned luminescence of La$_2$O$_2$CN$_2$:Eu$^{3+}$ nanostructures can be obtained by changing the doping concentration of Eu$^{3+}$ and the morphologies of nanostructures. The new strategy and construct technique are of universal significance to fabricate other earth oxycyanamide nanostructures with various morphologies.
